PSYCHO'LOGY. (Gr. ψυχὴ, *the soul*, and λόγος, *discourse.*) In its larger acceptation, may be taken as synonymous with mental philosophy. The word is more frequently used in reference to the lower faculties of the mind, and the classification of the phenomena which they present. All psychology is built on experience, either immediate, or revived by the memory and imagination. But, in reflecting on our intellectual faculties, we discover in them certain laws, which, as soon as they are presented to us, we at once recognise as universal and necessary; certain conditions without the fulfilment of which we are sensible that no act of intellection could have taken place. This universality is something very different from the empirical truth, as a matter of fact, which we attribute to the laws of association, which are, indeed, universal, but which might, for aught we can see, have been different from what they are. Corresponding to this distinction, German writers have discriminated between a higher, or rational, and a lower, or empirical psychology: the first, that of Kant, who sought, in all our mental faculties, to determine that only which is necessary and immutable; the second, that of Hartley, who treats all our intellectual acts as alike objects of mere history, dependent for their validity only on the fact that they do really recur in such and such order. The psychology of Aristotle was of the latter description. He, consequently, regarded the science as forming one of the physical sciences, or those which are conversant with the contingent and changeable. Many pregnant psychological truths are discoverable in that philosopher's work on the soul; in particular, the doctrine of association, the master-light of all sound experimental psychology, owes its first enunciation to him. Among later writers who have made valuable contributions to the science may be enumerated Hobbes, Locke, Hartley, and Sir Thomas Brown. The value of these authors' writings in this peculiar province cannot be too highly appreciated. It is only when psychology intrudes upon the domain, or usurps the attributes, of the higher philosophy, that its claims need to be resisted. As a preparation for metaphysical and theological thought, and, indeed, as an indispensable requisite for the science of man, whether history, politics, or ethics, it is not easy to exaggerate its importance.

PSYCHOMA'NCY. (Gr. ψυχη, and μαντεια, *prophecy.*) A species of divination, in which the dead were supposed to appear as spirits, to communicate the wished for information.

PSYCHRO'METER. (Gr. ψυχρος, *cool*; μετρον, *measure.*) An instrument invented by Professor August of Berlin, for measuring the tension of the aqueous vapour contained in the atmosphere. It consists of two very sensible thermometers, one of which, when an observation is to be made, has its bulb kept moistened, but so that no drop of water remains suspended from it. The thermometers being then freely exposed to the air, the temperature indicated by each is observed, and also the height of the barometer, from which data the tension of the vapour is computed by means of this formula:—

$$e = e' - 0{\cdot}00081482\,(t - t')\,b\,;$$

where b is the height of the barometer (in Paris lines), t the temperature of the air (in centesimal degrees), t' the temperature of the wet bulb, e' the tension of vapour corresponding to the temperature t', and e the tension of the vapour actually contained in the air. The instrument is described in the work of August, *Sur les Progrès de l'Hygrométrie dans les Derniers Temps*, Berlin, 1830; also in the *Lehrbuch der Meteorologie* of Kœmptz; and *Quetelet's Correspondence Mathématique et Physique*, 3me série, tome 2.

PTERODA'CTYLE, *Pterodactylus.* (Gr. πτερον, *a wing*, δακτυλος, *a digit.*) The name of a genus of extinct reptiles, in which the second digit of the hand is of extreme length, and is considered to have supported an aliform expansion of the skin.

PTE'ROPODS, *Pteropoda.* (Gr. πτερον, and πους, *a foot.*) The name of a class of Mollusks, comprehending those which have a natatory wing-shaped expansion on each side of the head and neck.

PTERY'GIANS. *Pterygia.* (Gr. πτερυξ, *a wing.*) A name applied by Latreille to a group of Mollusks, corresponding to the Cephalopods and Pteropods of Cuvier, both of which have locomotive organs, composed of wing-like expansions of the skin.

PTERY'GODA. (Gr. πτερυξ.) Latreille has given this term to two small, hard, moveable bodies, in the form of little elytra, directed backwards, and terminating at the origin of the wings. They arise from the two sides of the anterior extremity of the trunk, near the exterior base of the two first legs, instead of from the second segment of the trunk, like true elytra. They are present in Lepidopterous and Strepsipterous insects.

PTERY'GOID. (Gr. πτερυξ, and ειδος, *form.*) Wing-shaped. The name is applied to processes of the sphenoid bone, which complete the osseous palate behind, and form distinct bones in the oviparous vertebrate animals.

PTI'SAN. (Gr. πτισσω, *I bruise.*) A weak diluent drink.

PTOLEMAIC SYSTEM. *See* ASTRONOMY.

PTOLEMA'ITES. A sect of ancient heretics among the Gnostics, who maintained that the Mosaic Law came partly from God, partly from Moses, and partly from the traditions of the Jewish doctors. (See *Mosheim's Church History.*)

PTY'ALISM. (Gr. πτυαλιζω, *I spit.*) An increased flow of saliva. Salivation.

PUBE'SCENT. (Lat. pubescens, *hairy.*) In Zoology, when a part or whole is covered with very fine recumbent short hairs.

PU'BLICANS. (Lat. publicani.) The farmers of the public revenue of Rome. They formed two distinct classes; the farmers-general of the revenues, who were regarded as belonging to one of the most honourable grades of citizens, and deputies or under publicans of an inferior caste, whose reputation was on a par with that of the most degraded citizens. Hence, in the New Testament, the τελωναι, a word rendered publicans by the Latin translators, are almost always placed in juxtaposition with sinners. (See *Milman's Hist. of Christianity.*) This term was also applied as a nickname to the Albigenses, which see.

PUBLIC SAFETY, COMMITTEE OF. (French Revolution.) This famous body was formed out of the convention, April 6. 1793, and invested with very general powers to provide for the supposed welfare of the state; even the power of arrest and imprisonment was soon conferred upon it. After the downfall of the Girondist party (*see* GIRONDISTES), this committee became the virtual government of France, by a decree of Dec. 4. 1793. Its members were, at this period, elected every month, but in general the same were re-elected. From this period its history is, in effect, that of the revolution. It appointed tribunals, composed of committees, invested with sovereign power to try offences against the state, over the whole country. It was in the committee of public safety that the opposition to Robespierre originated; but, on the overthrow of that personage, its powers were limited by the convention; and, on the introduction of the new constitutiton of October, 1794, it became extinct along with the assembly out of which it had been formed.

PUCK. In Mediæval Mythology, the "merry wanderer of the night," whose character and attributes are so beautifully depicted in the *Midsummer Night's Dream.* This celebrated fairy is known by a variety of names; as *Robin good-fellow* and *Friar Rush* in England; and in Germany, as *Knecht Ruprecht;* but it is by his designation of Puck, that he is most generally known both in England, Germany, and the more northern nations. He was the chief of the domestic tribe of fairies, or *brownies*, as they are called in Scotland; and innumerable stories are told of his nocturnal exploits, among which, drawing the wine, and cleaning the kitchen while the family were asleep, are the most prominent. The word is probably derived from the old Scandinavian pûki, *a boy;* it is also synonymous with pug, or monkey, whose form this fairy is said to have most frequently assumed.

PU'DDING-STONE. A conglomerate of rounded pebbles cemented together by a fine-grained and generally silicious or sandy paste. When select specimens are cut and polished, they resemble a section of a plum-pudding, and are often used for ornamental purposes, such as snuff-boxes and slabs.

PUE'RPERAL FEVER. A fever attended by peritoneal inflammation, which comes on about the third day

after delivery. The usual febrile symptoms are attended with great tenseness and tenderness of the abdomen; the milk disappears, and the bowels are usually affected by diarrhœa. It is most common in the autumn, and appears to be contagious. It is an alarming disease, and requires great promptitude and judgment in its treatment. Bleeding, modified according to the circumstances of the case, purging with calomel, saline sudorifics, and occasionally opium, to quiet pain and induce rest, are among the remedial means; but it often happens that great irritability of the stomach and bowels, or even incessant purging and vomiting, are predominant symptoms, and the fever assumes a typhoid character, in which case the system requires support from cordials.

PU'GGING. In Architecture, the stuff made of plaster laid on the sounding boarding under the boards of a floor, to deaden the sound between one story and another.

PU'GIL. (Lat. pugillus.) A quantity of any thing which may be taken up between the thumb and two fingers.

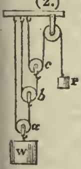
PUISNE JUDGE. (Norm. Fr. puisné, *younger*.) The judges and barons of the King's Bench, Common Pleas, and Exchequer, with the exception of the chief justices and chief baron, are so called.

PU'LLEY. In Mechanics, one of the six simple machines, or mechanical powers. It consists of a wheel, moveable about an axis, and having a groove cut in its circumference, over which a cord passes. The axle is supported by a box or sheave, called the *block*, which may either be moveable, or fixed to a firm support.

(1.)

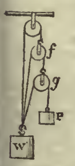
A single pulley serves merely to change the direction of motion; but several of them may be combined in various ways, by which a mechanical advantage or *purchase* is gained, greater or less, according to their number and the mode of combination. The purchase gained by any combination is readily computed by comparing the celerity of the weight raised with that of the moving power, according to the principle of virtual velocities, which is alike applicable to all machines of whatever kind. In fig. 1., which represents a system where the several portions of the cord are parallel to each other, suppose the weight W to rise 1 inch, the two blocks would approach each other by that quantity, and, consequently, the length of cord connecting a single pair of pulleys would be shortened by 2 inches, so that the power P would descend 2 inches. Let the number of pulleys in each block be n; then, while the weight ascends 1 inch, the power descends $2n$ inches, and, consequently, when there is equilibrium, the power is to the weight as 1 to $2n$.

(2.)



In the combination represented in fig. 2., the purchase is much greater. Here the pulleys are all moveable, and each is supported by a separate cord, having one end fastened to a fixed obstacle and the other attached to the succeeding pulley, excepting the upper block which is fixed. It is evident that, for every inch the weight on the first pulley a ascends, the second, b, ascends two; the third, c, ascends four, and so on; the velocity being doubled by each additional pulley. The purchase finally obtained is, therefore, $= 2^n$; or the power is to the weight as $1 : 2^n$.

The third combination, fig. 3., has still greater efficacy.



In this system, each cord is fastened to the weight, and, passing over a pulley, is attached to another pulley, excepting the last, which supports the power. While the weight W rises 1 inch, the first moveable pulley, f, will sink 1 inch, which allows the cord applied to it to slacken 2 inches, and this joined to the inch which the weight ascends allows the second moveable pulley, g, to descend 3 inches. This allows the next pulley in succession to descend 6 inches, which, joined to the 1 inch which the weight ascends, gives 7 inches for the descent of the third pulley. In like manner, it is found that the descent of the fourth pulley is 15 inches. Hence, one moveable pulley allows the weight to descend $2 \times 1 + 1 = 3$ inches; two such pulleys, $2 \times 3 + 1 = 7$ inches; 3 pulleys, $2 \times 7 + 1 = 15$ inches; four pulleys, $2 \times 15 + 1 = 31$ inches; and so on; so that the purchase obtained by n moveable pulleys is $2^{n+1} - 1$, or the power is to the weight as 1 to $2^{n+1} - 1$. The theoretical advantage thus computed is, however, in all the cases, greatly diminished by friction, and the rigidity of the rope.

The two last combinations are of little, if any, use in practice, but various modifications of the first are common. *Smeaton's pully*, or *Smeaton's tack*, as it is usually called, contains two rows of wheels, one under the other, in each block, and a single cord is made to pass over them in such a manner that the power and the weight both act in the same line with the centres of the two blocks, so that there is no tendency to twist. But this ingenious arrangement is open to several objections, and particularly the great amount of lateral friction of so many independent wheels. In White's pulley (see *fig.* 1.), the wheels in each block turn on the same axis, and consequently revolve in the same time; and they are of different sizes, their dimensions being so proportioned that a point on the circumference of any wheel moves with the velocity of the rope on that wheel. To effect this the diameter of the wheels in the upper block must be as the numbers 1, 3, 5, &c., and in the lower as 2, 4, 6, &c. Instead of separate wheels, the upper and lower blocks are cut in grooves in the above proportions, whereby the friction is reduced to that of one wheel in each block.

PU'LMOGRADES, *Pulmograda*. (Lat. pulmo, *a lung*, gradior, *I advance*.) The name of a tribe of Acalephans, including those gelatinous species which swim by the contraction of the vascular margin of the disk-shaped body, where respiration, also, probably takes place.

PU'LMONARIES, *Pulmonaria*. The name of the order of Arachnidans, including those which breathe by means of pulmonary sacs or lungs.

PU'LMONATES, *Pulmonata*. The name of an order of Gastropodous Mollusks, including those which breathe air, to which the blood is exposed while circulating through a vascular network which lines the internal surface of the bronchial cavity.

The order is subdivided into the *Pulmonata terrestria*, comprehending the Linnæan genera *Limax* and *Helix*, with *Clausilia*, Drap., and *Achatina*, Lam.; and the *Pulmonata aquatica*, comprehending the genera *Onchidium*, Buchanan; *Planorbis*, Cuv.; *Lymnæa*, Lam.; *Physa*, Drap.; *Auricula*, Lam.; *Conovulus*, Lam.

PU'LPIT. (Lat. pulpitum.) In Architecture, the raised part in a public building from which an oration is delivered. In the ancient theatre it was the higher part of the stage whereon the musicians stood.

PULSE. (Lat. pulsus.) The pulsation of the arteries, depending upon the impulse given to the blood by the action of the heart. (*See* HEART.) The pulse is usually felt by pressing the *radial artery* at the wrist, and the rapidity, regularity, and force of the circulation is thus judged of, and furnishes an important criterion of the phenomena and progress of disease. The range of the pulse as to *frequency*, in a healthy adult, is usually between 60 and 80, but there are persons whose pulses rarely beat 60 times in a minute, and others, not out of health, in whom the frequency exceeds 80; the pulse, in short, is extremely capricious, and before any correct inferences can be drawn from it, the peculiarities of each individual require to be carefully considered; slight mental affections, indigestion, irritability, and many other causes producing modifications of the pulse, do not admit of any general description. The terms *hard*, *full*, *soft*, and *wiry* pulse, are used to indicate other obvious modifications independent of the number of pulsations. The average rate of the pulse of a healthy infant is, for the first year, from about 120 to 108; for the second year, from 108 to 90; for the third, from 100 to 80; from the seventh to the twelfth year, the pulsations are about 70. When the pulse exceeds 140 beats in a minute it is not easy to count it precisely, and to this it attains in some febrile diseases.

An *intermitting pulse* is by no means uncommon, and often produced by trivial causes: with many persons in perfect health the pulse will be subject to very extraordinary irregularities; and there are cases on record in which a person's pulse which has always intermitted in a state of health has acquired regularity on the accession of disease. The state of the digestive organs has often a marked influence upon this condition of the pulse.

PULSE. Leguminous plants cultivated for their pods or seeds, such as the pea, bean, kidney-bean, &c.

PULVI'LLI, in Entomology, are the cushions of short hairs very closely set, or a membrane capable of being inflated, or very soft and concave plates, which cover the underside, or their apex, of the four first joints of the manus or tarsus, and sometimes even of the ends of the moveable spines situated at the apex of the *tibia*, which act so as to produce a vacuum, and enable the insect to suspend itself, or walk against gravity.

PU'LVINATED. (Lat. pulvinar, *a pillow*.) In Architecture, a term used to express a swelling in any portion of an order, such, for instance, as that of the frieze in the modern Ionic order.

PU'MICE. (Lat. pumex.) A porous volcanic product, consisting chiefly of silica and alumina, with traces of potash, soda, and oxide of iron.

PUMP. A machine for raising water. Though the forms under which this useful engine is constructed, and the mode in which the power is applied, may be modified

in an infinite number of ways, there are only three which can be considered as differing from each other in principle. These are, the *sucking pump*, the *forcing pump*, and the *lifting pump*, so called from the manner in which they act

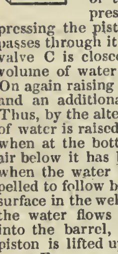
The *sucking pump*, or common household pump, is an apparatus of which the principle and construction will be evident from the annexed figure. A A is a pipe of any convenient length, the lower end of which reaches below the surface of the water in the well or reservoir; B is a barrel, generally of greater diameter than the pipe; C a valve opening upwards; D a piston moved by the rod E: in this piston there is also a valve opening upwards. When the piston is raised, the air in the barrel between the valves is expanded, and its tension consequently diminished; the pressure of the air in the pipe, therefore, opens the valve C, and the whole air in the pipe and barrel becomes less dense. In this state the atmospheric pressure on the surface of the water causes it to rise in the pipe, until the tension of the confined air becomes equal to the pressure of the atmosphere. On again depressing the piston, the valve in it opens, and the air passes through it from the barrel as it descends; but the valve C is closed by the downward pressure, and the volume of water which has entered the pipe remains. On again raising the piston, the same effect is repeated, and an additional quantity of water enters the pipe. Thus, by the alternating motion of the piston, a column of water is raised in the pipe until it reaches the piston when at the bottom of the barrel, and the whole of the air below it has been excluded. On raising the piston when the water has reached it, the fluid will be compelled to follow by the pressure of the atmosphere on its surface in the well. When the piston is again depressed, the water flows through the valve in it, and ascends into the barrel, and by the succeeding strokes of the piston is lifted up until it reaches and flows out of the spout F.

(1.)

Although in theory the limit of the height to which water may be raised by the sucking pump, from the surface of the fluid in the well to the highest position of the moveable piston, is about 34 feet (the height of a column of water which balances the pressure of the atmosphere), it is not found practicable, with pumps of the ordinary construction, to raise it more than about 28 feet. The difference arises from the difficulty of making the apparatus absolutely air-tight.

The *forcing pump* is represented in fig. 2. The piston-rod E D is attached to a solid plunger D, adjusted to the cavity of the barrel. A pipe G H, furnished with a valve F, opening outwards, communicates with the barrel at G. On elevating the plunger D, the water will ascend through the valve C, in the same manner as in the sucking pump, till the barrel is filled to D. Now, when the plunger is depressed the valve C will shut, and the water between D and C be forced through the valve F into the pipe G H. When the plunger is raised, the valve at F shuts, the pressure on its under side being removed, so that the water which was forced into the pipe by the previous stroke cannot return into the barrel. At the next stroke of the piston more water is again forced into the pipe, and so on till it is raised to the height required.

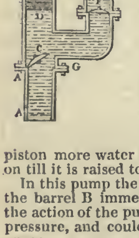
(2.)



In this pump the pipe A A may be dispensed with, and the barrel B immersed in the reservoir; in which case the action of the pump is independent of the atmospheric pressure, and could be maintained equally well in a vacuum.

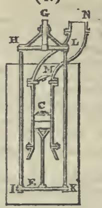
In order to produce a continued stream through the pipe G H, an air vessel, *m n*, may be attached to the lateral branch above the valve F, fig. 3. The pipe G H reaches to near the bottom of the air vessel; and when the water has been forced into the vessel by the action of the pump, until it reaches above the lower end of the pipe at G, it is evident that, as all communication is then cut off with the external atmosphere, every additional quantity of water thrown into the vessel will tend more and more to compress the air within it, which, acting by its pressure on the surface of the water, forces it through the pipe G H in a continued stream.

(3.)



The *lifting pump* is represented by fig. 4. The barrel of the pump is immersed in the water and fixed to an immoveable frame. The piston with its bucket and valve C, opening upwards, is attached at E to another frame, G H I K L, consisting of two strong iron rods, H I and L K, which move through holes in the frame-work to which the pump is fixed. An inclined branch M N, either fixed to the top of the barrel, or moveable by means of a ball and socket, is fitted exactly to the barrel, and furnished with a valve at M. Suppose the barrel immersed in the water to a certain depth: if the piston frame be now thrust down by the handle at G, the piston will descend, and the water be forced by its upward pressure through the valve C, so as to maintain the same level in the pump as in the well. But when the piston frame is elevated, the valve C will shut (as shown in the figure), and the water above C be *lifted up* with the piston, and forced through the valve M into the branch M N, from which its return will be prevented by the shutting of the valve M when the piston descends.

(4.)



In each of these different kinds of pumps which have been described, the total effort required to work the machine, independently of friction, is equal to the weight of a column of water, the base of which is equal to the area of a section of the working barrel, and the altitude equal to the distance between the surface of the water in the reservoir and the point to which it is raised. In the sucking pump the whole of this effort is expended in raising the piston; in the forcing pump, one part is expended in raising and the other in depressing the piston, and it is advantageous to dispose the machinery so that these two parts shall be nearly equal. In small pumps for domestic purpose, the strength of man is usually employed as the moving power; but in raising water from great depths, as the bottoms of mines, the steam engine is applied to this purpose. (*See* FIRE ENGINE.) For an account of the mechanism of different kinds of pumps, see *Gregory's Mechanics*, vol. ii.

The *chain pump* used in ships of war consists of an endless chain moving over a wheel on the gun deck, which is turned round by winches, and over a roller in the pump-well, having saucers or flat circular pistons at certain intervals. Near the pump-well, on the side on which the chain on turning the winches ascends, are a few feet of pipe; through this the saucers raise the column of water, which, being lifted over the upper orifice of the pipe, falls into the cistern, and thence into the waste-pipe, called the *pump-dale*, which carries it overboard. The descending portion of chain falls through another case called the *back case*. Chain pumps, in large ships, throw out a ton a minute.

PU'MPERNI'CKEL. The name of a species of bread peculiar to Westphalia: it consists of bran, has a little acidity, but is agreeable to the taste, and very nourishing; and remains moist for several months. It forms the chief food of the Westphalian peasants; but it is regarded as a great delicacy in other parts of Germany, whither it is exported in large quantities. They sometimes weigh 60 lbs. The term is said to be of French derivation, and originated in a French soldier having rejected the bread with disgust, exclaiming, "C'est bon pour Nickel;" *i. e.* for his horse.

PUN. A play upon words, the wit or point of which depends on a resemblance between the sound and syllables of two or more words, which have different, and perhaps opposite, meanings. *See* PARONOMASIA.

PU'NCHEON. In Architecture, a short post. The small quarters in a partition above the head of a door are called puncheons.

PUNCHEON. A measure of capacity for liquids, containing 84 gallons, or one third of a tun.

PU'NCTATE. (Lat. punctum, *a point*.) In Zoology, when a part is beset with many points, or minute impressions, which do not perforate the surface.

PUNCTUA'TION. In Writing, the dividing words, propositions, or sentences from each other by means of certain marks or points, designed to facilitate the apprehension, or to regulate the enunciation of written language. Points or stops are said to have been first used by Aristophanes, the Alexandrian grammarian; but the modern system of punctuation is due to Manutius, a learned printer, who lived at Venice in the 15th and 16th centuries. The marks most commonly in use are, 1. The comma (,), which is placed between the less important divisions of a sentence or passage; as, for instance, before and after qualifying propositions or clauses; between single words not connected by conjunctions; before conjunctions which unite sentences, &c. 2. The semicolon (;), which distinguishes the longer or more important members of a sentence; as when the latter part is an inference from, or qualification, explanation, or illustration of, the former. 3. The colon (:), which is chiefly used to distinguish such members of a sentence as are themselves divided by semicolons into two or more principal

parts. 4. The period or full stop (.), which stands at the end of a complete sentence. Besides these may be enumerated the note of interrogation (?) or inquiry; of exclamation (!), expressing admiration, endearment, or any considerable emotion; the parenthesis ( ), used when a clause is inserted which interrupts the progress of the sentence; with other marks, either less commonly used, or the rules for whose use are less easily defined.

PU'NDIT (more correctly written Pandit). The title of learned Brahmins in Hindoostan. The term is used ironically in England to designate any one who makes a vast show of learning without possessing it in reality.

PU'NIC WARS. The name given to the celebrated contests in which the Romans and Carthaginians were engaged for more than three centuries, and which finally terminated in the destruction of Carthage. The first commenced A.C. 264, and ended A.C. 241; the second lasted from A.C. 218 to A.C. 202; the third from A.C. 149 to A.C. 147, ending with the destruction of Carthage.

PU'NISHMENT. (Lat. pœna, *punishment.*) In Jurisprudence, the infliction of suffering, under legal sanction, upon those who have violated the law.

It is undoubtedly true, that both in legislation and in public opinion respecting punishment, the *vindictive* theory which considered it as a retribution for crime, and to be governed by our moral feelings of indignation against the offender, has far too generally prevailed, and that the primary end, the interests of society, has been overlooked. But we are not quite certain whether the present course of opinion does not run too exclusively in the contrary direction; and whether those who adopt the common formula, that "the object of all punishment is the prevention of the offence in future," have reflected on all the consequences of that position.

For instance, it is the common practice in this country as well as in others, to connect the administration of justice with the enforcement of the tenets of religion and morality. In passing sentence, wherever there is any peculiarity in the case calculated to call forth such observation, the judge rarely fails to comment on the moral deformity of the act; not merely in its tendency to injure society, but subjectively, as evidencing moral depravity in the person committing it. The solemnities of public worship which form part of the ceremonial; the public harangues of the judges (as, for instance, in the English custom of charging the grand jury); the language in which the jury is commonly addressed, both by the judge and the advocates; all these seem based on the assumption, that the moral quality of acts is one of the matters to be brought under their consideration. But if the judge has really no concern whatever with that moral quality, and is simply there to see that society may be guarded, as far as possible, from exposure to material injury by fraud or violence, all these ceremonies are utterly out of place. They must either be defended as politic devices, employing the machinery of religion to aid in terrifying offenders from the commission of crime; or as concessions to popular ignorance. And it is certain that in such a case they had far better be abolished altogether, as they strongly lead the mind to dwell on that false view of the object of punishment, which it is the object of Bentham and his school to extirpate.

Again, in popular estimation, the moral atrocity of an offence is one of the elements in the correct measure of punishment. On whatever ground philosophers may object to sanguinary laws, this plain objection is that which has always prevailed in the public mind. In the case of forgery, for example, the feeling of the majority triumphed in the end over the severity of the law, not because it was thought disproportioned to the injury inflicted on society, or to the importance of repressing the crime, but because it was thought not to deserve it in a moral point of view. Now all such expression of sentiment, on the theory in question, is founded on a wrong principle; and the writers who adhere to it are forced to admit this feeling as a disturbing cause, preventing the right doctrine from being fully carried out; they are forced to admit, as part of their definition of a good punishment, that it shall not be such as to shock the popular notion of moral justice; which is, in other words, to admit that penal laws must be governed in part by principles which they condemn as altogether wrong; a very mischievous concession for a legislator to make.

That the interest of society is the great object of punishment must be conceded on all hands. That the specific object of preventing the offence from being committed is a very important part of that general object, probably by far the most important, may also be conceded. But the question is, whether the general object does not comprehend other particular objects also; and whether a punishment, which should answer in the highest degree the advantage of repressing that particular offence, or class of offences, might not be imperfect notwithstanding.

This question can only be solved by deciding the great preliminary difficulty of political science, in which so many others are involved; whether the ruling power, which we call the state, or society, or the legislature, has or has not any *moral* authority. Those who conclude that it has nothing to do beyond preserving the personal security and property of individuals, of course deny that it has any. But those who believe that it has, also, what may be termed a paternal power, and is entrusted by Providence with the maintenance of religion and moral principle, must, consistently, admit that there may be a moral object in punishment beyond the mere prevention of the offence.

And it must be observed in passing, that those who do hold the state to possess such a moral authority, and have such moral duties imposed upon it, need not, therefore, hold those to be its principal objects. It may very well be that the primary object of the association of men in a political body is security and self defence; yet that association may have other ends not inconsistent with this. And although those other ends are in themselves incomparably the most important, it does not at all follow that they are the most important as regards the state. When men enter into a particular contract with each other, their mutual duties under that contract are primarily those connected with the object of that contract; they may have other and more important mutual duties, which yet, as regards that contract, are secondary. No religious man will deny that the connexion of master and servant involves some duties of a very exalted character; but the principal object of that connexion is, nevertheless, the rendering of service in lieu of a remuneration.

We have not space here to pursue this line of reasoning; but must proceed to take the moral vocation of the state as admitted, and consider the effect of that admission on the theory of punishment. In the first place, it would be a mistake to suppose that it justifies retribution as an object of punishment. No one can apportion retributive justice who cannot judge of the motives of actions. The moral authority of the state, even by those who have carried its divine character to the highest point, has only been likened to the paternal; and no father has the right to chastise a child by way of retribution. He has no right to punish at all, except with a view to reformation. Omitting this mistaken end, the real objects of punishment may be classed as follows: —

1. The interests of society; which must be subdivided into,

i. Its security from the injury to person or property occasioned by the crime.

ii. Its moral and religious improvement.

And 2. The reformation of the offender. This is admitted as one of the ends of punishment by all writers; but Bentham and his followers regard it as such only so far as it conduces to the security of society by preventing the repetition of the offence; those who embrace the higher view, both on this account, and also as the fulfilment of the duty of the state towards the offender himself. Considered in either view, it is clearly a secondary object only, the good of society being the first.

The security of society is attained by punishment in four ways:

1. By forcibly preventing the offender from repeating his offence: as by death, mutilation, or perpetual imprisonment.

2. By reforming the habits of the offender, and thereby taking away the desire.

3. By deterring the offender from repetition by the fear of fresh punishment.

4. By deterring others through example. And this last is clearly the chief practical end of all legal inflictions. The admission of other principles, while it seems necessary in order to satisfy our conception of the existence of the state as a moral agent, need not prevent the legislator from keeping this steadily in view.

Our limits forbid us from pursuing farther the analysis of punishment, and pointing out in what manner the different kinds and degree of it principally in use follow, or depart from, their legitimate ends. We will conclude with the classification of punishments given by Bentham, in his *Theorie des Peines*, to use the title of the work as given by his translator Dumont. If Bentham's theory be defective in its main principles (and although we have presented the reader with some arguments against it, we do not assert that they must be conclusive with all), it is at all events only from being imperfect, not erroneous; as far as it goes, it is logical, consistent, and definite. And as he was nearly the first writer who introduced anything like clearness or arrangement into the popular notions on penal laws, so we are inclined to think that, on the whole, he has done more for society in this particular than in any other of the various subjects to which he applied his reforming genius. It must not be forgotten that Sir S. Romilly and Sir J. Mackintosh were the pupils who carried his speculations into practice.

He divides punishments into corporeal and privative. The first of these are, 1. Simply afflictive, those which consist in the mere infliction of temporary pains, the lash, &c. 2. Complexly afflictive, in which pain is joined

with permanent loss: as in the old punishments of mutilation and disfigurement. 3. Restrictive, under which he classes together (perhaps rather inappropriately) imprisonment, or the total deprivation of liberty, and banishment, which deprives of a certain portion of liberty. 4. Active or laborious; such as the gallies, hard labour, &c. Transportation combines this character with the former. 5. Privative punishments are those which deprive the criminal, 1. Of life; 2. Of reputation *only;* such, perhaps, as the amende in French law. 3. Of property: fine, and confiscations. 4. Forfeiture of condition; which, more or less, accompanies infamous punishments in most countries: *e. g.* civil infamy, in France, is attended with various disabilities. These eight comprehend all the simple forms of punishment in ordinary use; but he adds a few, which he terms anomalous, and only mentions to hold them up to general reprobation. 1. What he calls *vicarious* punishments; as when the family of a suicide are punished by the forfeiture of his chattels. 2. Transitive; when the penalty passes to future generations: corruption of blood in the English law. 3. Collective, of which he gives, as an instance, the punishment of corporations for the acts of individual corporators; a more ordinary one is, the compelling the inhabitants of a hundred to make good the damages occasioned by a riot. 4. Fortuitous; where individuals wholly unconnected with the offender are implicated, as it were casually, in the consequences of his crime; of which he gives, as an instance, the avoidance of mesne conveyances by some kinds of confiscation, and consequent loss of innocent purchasers; and the imposition of deodands, where no negligence is imputed. (See also *Ed. Rev.* vol. xxii., where his work is reviewed; Lucas, *Système Pénal.*)

PU'PA. (Lat. pupa, *a puppet.*) A genus of land snails, so called from the resemblance of the shell to the pupe, or chrysalis of an insect. Several species are British, as *Pupa umbilicata*, Drap.; *P. marginata*, Drap.; *P. edentula*, Drap.

PUPE. (Lat. pupa.) The name of the oviform nymphs of Lepidopterous insects; also applied to Metabolian insects generally, when in the second stage of their metamorphosis.

PU'PIL. (Lat. pupa.) A term applied to the central opening of the eye, because it reflects the diminished image of the person who looks into it. It is the central aperture of the *iris*.

PU'PIPARES, *Pupipara*. (Lat. pupa, and pario, *I bring forth.*) Those insects are said to be pupiparous which produce their young in the condition of a pupe or nymph; as the forest-fly, *Hippobosca equina.*

PU'PIVORES, *Pupivora.* (Lat. pupa and voro, *I devour.*) The name of a tribe of Hymenopterous insects, comprehending those of which the larvæ live parasitically in the interior of the larvæ and pupæ of other insects.

PURA'NA. (Sanscrit, *a poem.*) The sacred books of India which contain the explanation of the Shaster (which see). There are eighteen books of the Puranas; chiefly filled with legends of the inferior gods and the heroes of Hindostan. (See *Mém. de l'Acad. des Inscr.* vol. xxxviii.) It should be stated, that Professor Wilson intimates his disbelief of the received opinion as to the great antiquity of the Puranas, and believes the writings now known under that name to be mere imitations of lost originals. (Preface to his translation of the *Vishnu Purana.*) See *Asiatic Journal*, Dec. 1840.

PURBECK LIMESTONE. *See* GEOLOGY.

PU'RCHASE, in Law, means, generally, the acquisition of lands or tenements by any other means than descent; as by devise, gift, deed, or agreement.

PU'RGATORY. A place appointed for the satisfaction of temporal punishments, which, according to the Roman Catholic church, are distinguished from the eternal, of which the latter only are remitted to us by the death of Christ. There is none perhaps of the peculiar articles of the Romish faith in favour of which so little can be advanced from the language of scripture; and it may be safely averred that it was not from that source that the opinion ever gained possession of men's minds. It seems to be a natural but too strict an inference from the imperfectly disclosed economy of the divine judgments, which we find to admit of every degree of severity in this life, and are liable to conclude from analogy must be subject to some equivalent adjustment in the next. Accordingly, we discover some imperfect recognitions of the idea in individual writers several centuries before it can be proved that it formed an established article of faith. Augustin is considered the earliest of these; and he speaks vaguely and inconsistently. It was first inculcated as a doctrine by Gregory the Great, who seems to have connected it with the then popular belief that the world was closely approaching to its end. It was much discussed between the Greeks and Latins at the council of Ferrara, 1438. The present Roman Catholic belief is thus expressed in the creed of Pope Pius IV.: —"Constanter teneo purgatorium esse, animasque ibi detentas suffragio fidelium juvari." To which it may be added, that the sins punished in Purgatory are of two kinds,—mortal, repented of; and venial. This article of the creed is derived from the canon of the council of Trent on the subject, sess. 25. The "Romish doctrine" of Purgatory is condemned by Art. 22. of our church. The reader will find the general argument for Purgatory well stated (among Protestants) by Hooker in his 3d Sermon: the latter part, in which he replied to it, is lost. It is also set forth with much learning and moderation in *Tracts for the Times*, No. 79.

PURIFICATION. An observance enjoined by the law of Moses upon occasion of certain accidental defilements, which are scrupulously recorded in the Levitical code. The purification was generally by water; and in the case of women, who were considered impure after childbirth for the space of forty days if delivered of a male, and eighty if of a female, the offering of a lamb and some other sacrifices was required. The purification of the Virgin Mary is a festival in the calendar, and is observed on the 2d of February, being forty days after Christmas. This festival was established in the 6th century, and is variously termed in ecclesiastical antiquities by the names of ὑπαπαντη, Festum Candelarum, Candlemas, the Presentation. The processions of this day were instituted by Gregory the Great. For an account of the ceremonies of purification among the Greeks and Romans, see the article LUSTRATION.

PU'RIM. The name of the solemn festival among the Jews in which they commemorate their deliverance from the wiles and stratagems of Haman, as recorded in the book of Esther. The observance of this festival has been religiously maintained by all the Hebrew race from its institution down to the present time. It is held in February.

PU'RIST. A name sometimes applied to rigorous critics of purity in literary style.

PU'RITANS. The name by which the dissenters from the church of England were generally known in the reign of Elizabeth and the first two Stuarts. The term was assumed, as the word implies, from the superior purity of doctrine and discipline which the more violent reformers claimed as their own; maintaining that they followed the word of God alone, purified from all human inventions and superstitions, of which they believed the English church to retain a considerable share, notwithstanding its alleged reformation. According to Fuller, the use of the name commenced about 1564. (See *Neale's History of the Puritans.*) *See* DISSENTERS.

PU'RLINE. In Architecture, a piece of timber lying on the principal rafters to support them in the middle.

PU'RPLE. (Gr. πορφυρα.) In Painting, a colour produced by the mixture of red and blue, and thence partaking of the hue of each. Among the ancients, purple was always the distinguishing badge of power and distinction; and, of all the various kinds in use, the Tyrian dye is the most celebrated. This colour was produced from an animal juice found in a shell-fish called murex, or conchylium, the quality of which, however, varied with the different coasts on which it was caught.

PURPLE OF CASSIUS. A compound of the oxides of tin and gold, obtained by adding protochloride of tin to a solution of chloride of gold. The true nature of the compound has not been determined; it is used as a purple colour for porcelain painting, and also for staining glass, to which it imparts a fine ruby red.

PU'RPURA. An eruption of small purple specks and patches, caused by extravasation of blood under the cuticle; it is generally attended by constitutional debility, and often by fever. Aperient medicines, and sometimes purgatives, carried to a greater or less extent, followed by mild tonics, and in some cases by wine, bark, and acids, are the principal remedies; but, in the treatment, much will depend upon the concomitant symptoms.

In Zoology, *purpura* is a generic name of the univalve Gasteropod which secretes the purple fluid which formed the base of the Tyrian dye.

PU'RPURE. Purple. In Heraldry, one of the colours or tinctures used in blazonry. It is equivalent to amethyst among precious stones, Mercury among planets. In engraving it is represented by diagonal lines from the sinister to the dexter side of the escutcheon.

PURPU'RIC ACID. A substance resulting from the action of nitric acid upon uric acid; it forms deep red or *purple* compounds with most bases.

PURPU'RIFERS, *Purpurifera.* (Lat. purpura, *purple*, fero, *I bear.*) The name of a family of Gastropodous Mollusks, including those species which secrete the purple substance forming the celebrated dye of the ancients.

PU'RSER. An officer in the British navy, whose chief duty consists in keeping the accounts of the ship to which he belongs; but he also acts as purveyor.

PURSUIVA'NTS. In Heraldry, a kind of probationers in the Heralds' College of England, not admitted to the full privileges of the college, but advanced by succession into its higher offices. They are styled *Portcullis*, *Rouge Dragon*, *Blue Mantle*, and *Rouge Croix.*

PURVE'YANCE, or POURVEYANCE. (Fr. pourvoir, *to provide.*) In English Law, the providing necessaries for the king's house. The right of purveyance, or pre-emption, *i. e.* of buying necessaries for the household, impressing horses and carriages for use, or, on payment of a settled price, even against the will of the owner, was a valuable part of the ancient prerogatives of the kings of England, especially in times when the court was frequently in progress. It was abolished by 12 Ch. 2. c. 24., and has only been occasionally revived since that time by temporary acts for special purposes. The name of "purveyor" had long before become so odious, that by 36 Ed. 3. c. 2. it was changed into "buyer."

PUS. (Lat.) A bland yellowish fluid, somewhat like cream, found in abscesses, and formed upon the surfaces of what are termed healthy sores; it is heavier than water, and viewed under the microscope, appears composed of translucent globules floating in a colourless fluid.

PUTA'MEN. In Botany, the inner coat, or shell, or stone of a fruit; commonly called the endocarpium.

PU'TLOGS. (Etym. uncertain.) In Architecture, short pieces of timber used in scaffolds wherever the scaffold boards lie. They are placed at right angles to the wall, one end of them resting on the ledges of the scaffold, and the other on holes left in the wall.

PUTREFA'CTION. (Lat. putrefactio.) The spontaneous decomposition of animal and vegetable substances, attended by the evolution of fœtid gases. The putrefaction (or putrefactive fermentation) of animal substances is usually attended by more fœtid and noxious exhalations than those arising from vegetable products. This appears principally referable to the more abundant presence of nitrogen in the former; and hence those vegetables which abound in nitrogeniferous principles (such as most, if not all, of the cruciform plants) exhale peculiarly nauseous effluvia: hence, also, such animal products as are destitute of nitrogen are either unsusceptible of what is commonly called putrefaction, or suffer it slowly and imperfectly. The formation of ammonia, or of ammoniacal compounds, is a characteristic of most cases of animal putrefaction; while other combinations of hydrogen are also formed, especially carburetted hydrogen, together with complicated and often highly infectious vapours or gases, in which sulphur and phosphorus are frequently discerned. These putrefactive effluvia are for the most part easily decomposed, and resolved into new and comparatively innocuous compounds, by the agency of chlorine; hence the importance of that body as a powerful and rapidly acting disinfectant.

The rapidity of putrefaction, and the nature of its products, are to a great extent influenced by temperature, moisture, and access of air; they do not ensue below the freezing point, nor in dry substances, nor under the entire exclusion of oxygen; and hence various means suggest themselves of retarding or preventing putrefaction, as well as of modifying its results: a temperature between 60° and 80°, a due degree of humidity, and free access of air, are the circumstances under which it proceeds most rapidly. The most effective antiputrefactives or antiseptics are substances which either absorb or remove a portion of the water or moisture, and enter into new combinations with the organic matter; hence the great efficacy of certain salts, sugar, alcohol, and several other applications, among which, perhaps, the most remarkable are some of the volatile oils, such especially as kreasote and other empyreumatic products obtained by the destructive distillation of wood, and pyroligneous acid, and pyroligneous spirit; the latter is eminently useful in the preservation of dead bodies for the purposes of dissection, and, when properly and sufficiently injected into the vessels, and externally applied, indefinitely suspends all the ordinary steps of the putrefactive process.

The astringent or tanning principle of vegetables is also a powerful preserver of most organic tissues; it enters into chemical combination with the albuminous and gelatinous membranes and fibres; and the resulting compound, of which leather furnishes a characteristic example, is comparatively little prone to change, although the tanning material itself, as well as the animal principles with which it unites, are separately liable to decay.

Among saline substances, the antiputrefactive powers of salt are commonly known: when a piece of flesh is salted, brine runs from it, in consequence of the energy with which the salt abstracts the component water of the muscular fibre; the flesh becomes indurated, and its susceptibility to putrefactive changes greatly diminished; it becomes at the same time less easy of digestion as an article of food. Corrosive sublimate is a far more powerful preservative than common salt; and it appears to act not by the mere abstraction of water, but by entering into chemical union with the fibre. Sulphate of copper and several other metallic salts are similarly efficacious; and the most putrescible substances, such as the brain for instance, after having been steeped in such solutions and dried, will remain without further change for an indefinite period: the poisonous nature of these and many other metallic salts prevents their employment in the preservation of articles of food.

It is probable that the ancient Egyptians employed several of the above-mentioned antiputrefactive and preservative substances in the preparation of their mummies, which have remained for so many hundred years without signs of decay or decomposition; yet in these and similar cases, when by the careful application of various solvents the preservative substances are removed, the flesh resumes its susceptibility of putrefaction.

The inhabitants of northern climates avail themselves of freezing to prevent the putrefaction of their food, and the supplies of game and other articles in the Russian markets are retained in a frozen state; our fishmongers resort to the same expedient for the preservation of their unsold fish, which is daily removed to the ice-house after having been exhibited in their shops; salmon is packed in ice for the purpose of transport and preservation.

It is curious to remark the wonderful influence of vitality in opposing those chemical changes which constitute putrefaction, and in retaining that arrangement of the organic elements requisite for the functions of life; when a part of the body dies, the phenomena of gangrene or mortification ensue; that is, of local putrefaction: the putrefactive changes are the more energetic in consequence of the proximity of the dead part to the living.

All organic tissues may be indefinitely preserved by cautious desiccation; and it is in consequence of the absence of component water that the animal part of bone resists putrefaction: dried bones may thus be stored up for ages, and when it is required to extract their nutritive parts, these are found unimpaired.

PU'TTY. In Architecture, a very fine cement used by plasterers, made of lime only. It differs from *fine stuff* in the manner of preparing it, and in its being used without hair. Also a composition used by glaziers, consisting of oil, whiting, &c.

PY'CNITE, or SHORLOUS TOPAZ. (Gr. *πυκνος, thick.*) A prismatic mineral found at Altenburg in Saxony.

PY'CNOSTYLE. (Gr. *πυκνος*, and *στυλος, a column.*) In Architecture, an arrangement of columns, in which the intercolumniations are equal to one diameter and a half of the columns.

PY'GMY. *See* PIGMY.

PYLA'GORAS. (Gr. *πυλαγορας*, so called from the assembly of the Amphictyons at Thermopylæ.) The title of one of the two deputies from each confederate at the Amphyctyonic Council. His functions comprised the diplomatic and deliberative duties of the mission: while the care of the sacred rites fell on his colleague, the Hieromnemon (*ἱερομνημων*).

PYLORI'DEANS, *Pyloridea.* (Gr. *πυλη, an entrance, ουρος, a guard*, and *ειδος, form.*) The name of a tribe of Lamellibranchiate Bivalves, comprehending those which have a shell open at both extremities.

PYLO'RUS. (Gr. *πυλη, an entrance*, and *ουρος, a guard.*) The aperture of the stomach into the duodenum; it guards, as it were, the entrance into the intestinal canal.

PYRA'LLOITE. (Gr. *πυρ, fire*, and *αλλος, another.*) A mineral which undergoes various changes of colour when heated.

PY'RAMID. (Supposed to be from Gr. *πυρ, fire*, from the resemblance of the form to a spire of flame; but for a more probable derivation of the word, see *infrà*, PYRAMIDS OF EGYPT.) In Geometry, a solid contained by a plane polygonal base and other planes meeting in a point. This point is called the vertex of the pyramid; and the planes which meet in the vertex are called the sides, which are necessarily all triangles.

The principal properties of pyramids are the following: — 1. Every pyramid is equivalent to one third of a prism having the same base and altitude. Hence, 2. All pyramids having equivalent bases and equal altitudes are equivalent. 3. The solid content of a pyramid is measured by the product of the area of the base into one third of the altitude. 4. If a pyramid is cut by a plane parallel to its base, the frustum (or part comprehended between the base and the section) is equal to the sum of three pyramids having for their common altitude that of the frustum, and of which the bases are respectively the lower base of the frustum, the upper base of the frustum, and a mean proportional between them. (See *Legendre's Geometry*, and Notes.)

Pyramids are denominated from the figures of their bases, being triangular, quadrangular, pentagonal, &c., according as the base is a triangle, a quadrangle, a pentagon.

PYRAMIDS OF EGYPT. Celebrated monuments of* massive masonry, which, from a square base, rise by regular gradations till they terminate in a point, but so

* Chambers and galleries have been explored in some of the principal pyramids. Belzoni was the first whose investigations of the pyramids excited general attention; but more recently the researches of Colonel Howard Vyse have been attended with greater success. The

that the width of the base always exceeds the perpendicular height. The Pyramids commence immediately south of Cairo, but on the opposite bank of the Nile, and extend in an uninterrupted range for many miles in a southerly direction, parallel with the banks of the river.

The three largest are situated in the vicinity of Ghizeh, not far from Cairo; and of these the loftiest is called the pyramid of Cheops, from the prince by whom it is supposed to have been erected. The sides of its base, which are in the line of the four cardinal points, measure at the foundation 763·4 feet; so that it occupies a space of more than 13 acres. Its perpendicular height is 480 feet, being, consequently, 43 feet higher than St. Peter's at Rome, and 136 feet higher than St. Paul's. Supposing this pyramid to be entirely solid, its contents would exceed three millions of cubic yards, and the mass of stone contained in it would be six times as great as that contained in the Plymouth breakwater! (*Egyptian Antiquities*, *Library of Entertaining Knowledge*, ii. 213.) This huge fabric consists of successive tiers of vast blocks of calcareous stone, rising above each other in the form of steps. The thickness of the stones, which is identical with the height of the steps, decreases as the altitude of the pyramid increases, the greatest height being 4·628 ft. and the least 1·686 ft. The mean breadth of the steps is about 1 ft. 9 in. The best authorities agree in estimating the number of steps or tiers of stone at 203. According to the information communicated to Herodotus by the priests, 100,000 men were employed for twenty years in the construction of this prodigious edifice; and ten years were employed in constructing a causeway by which to convey the stones to the place, and in their conveyance. (Lib. ii. § 124.)

The other pyramids are of inferior dimensions; but they are mostly all, notwithstanding, of vast magnitude—*instar montium eductæ:* they are not all of stone, some of them being of brick.

Many learned dissertations have been written, and many fanciful and a few ingenious conjectures have been framed, to account for the original use and object of these imperishable structures. But the difficulty of the subject is such, that hitherto no satisfactory conclusion has been arrived at. Even in the remotest antiquity their origin was matter of doubt, and nothing certain was known with respect to them or their founders. (*Plin. Hist. Nat.* lib. 36. § 12.) On the whole, however, it would seem to be most probable that they were intimately connected with the religion of the ancient Egyptians; and that they were at once a species of tombs and temples, but participating more of the latter than of the former character. (For some remarks on this part of the subject, see *Shaw's Travels*, p. 170., &c. 4to. edit.; and *Greaves's Pyramidographia*, in his Works, vol. i.)

It has long been customary to regard the Pyramids as monuments merely of the power and folly of the monarchs by whom they were raised, and of the bondage of their subjects. This, however, seems to be a very superficial prejudiced view of the matter. The varying magnitude of the Pyramids, the fact of their being scattered over a space extending lengthwise about 70 miles, and their extraordinary number, appear to show pretty conclusively that they must have been constructed from a sense of utility or duty; and not out of caprice, or from a vain desire to perpetuate the names or the celebrity of the founders. If we had a sufficient knowledge of antiquity, it would probably be found that the motives which led to the construction of the Pyramids were, at bottom, nearly identical with those which led to the construction of St. Peter's and St. Paul's; and that they are monuments of the religion and piety, as well as of the power of the Pharaohs.

The Pyramids were esteemed by the ancients as one of the seven wonders of the world, and most deservedly; for it is impossible to look at these stupendous structures without being overwhelmed with a sense of their sublimity. They are associated, too, with some of the most interesting events in the history of the human race. Herodotus, Plato, and Pythagoras beheld them with wonder and admiration; Alexander the Great and Napoleon marshalled their hosts under their shadow; and they are probably destined to survive long after the proudest monuments of the present generation have crumbled into dust.

The etymology of the word *pyramid* is involved in as great obscurity as the object of the structures themselves. The most usual derivations that have been assigned to the term almost all proceeded on the supposition that it is of Greek origin, than which nothing can be more erroneous. Perhaps the most probable conjecture is that of De Sacy, which is as follows: — The ις in πυραμις he regards as a Greek termination; the first syllable πυ he holds to be the Greek version of the Egyptian article *pi* (and so written by the Greeks from their wish to derive the word from πυρ, *fire*); and he refers the syllable ραμ to the root *ram*, which, in the Egyptian language, signified *separating* or *setting apart from common use:* consequently, the word *pyramid* will denote a *sacred place or edifice* set apart for some religious purpose. (De Sacy, *Observations sur l'Origine du Nom donné par les Grecs et les Arabes aux Pyramides d'Ægypte.*) See *M'Culloch's Geog. Dict.*, art. "Egypt," and the authorities there cited.

latter gentleman has opened and explored four new chambers in the great pyramid; he also opened the third pyramid of Ghizeh, of the previous opening of which no tradition exists.

PYRAMIDAL NUMBERS, in Arithmetic, are numbers formed by the successive sums of polygonal numbers, in the same manner as the polygonal numbers are formed from arithmetical progressions. Thus —

Arithmetical progression,	1, 2, 3, 4, 5, &c.
Polygonal numbers,	1, 3, 6, 10, 15, &c.
Pyramidal numbers,	1, 4, 10, 20, 35, &c.

See FIGURATE NUMBERS and POLYGONAL NUMBERS.

PYRENE'ITE. A mineral found in the limestone of the French Pyrenees; it appears to be a variety of the garnet.

PYRETO'LOGY. (Gr. πυρετος, *fever*, and λογος, *a discourse*.) The doctrine of fevers.

PYRE'XIÆ. (Gr. πυρ, *fire*, and εξις, *habit*.) Fevers; diseases attended by fever.

PYRI'TES. (Gr. πυρ.) Sulphurets of copper and iron, commonly distinguished as copper and iron pyrites. The former is the principal ore of copper; the latter is an abundant natural product of a brass yellow colour. When exposed to air and moisture, especially after having been heated, it absorbs oxygen, and yields sulphate of iron, or green vitriol. The term is derived from πυρ, *fire;* either because they sometimes spontaneously ignite, or as being hard enough to strike fire with steel.

PYROACE'TIC SPIRIT. A liquid formed during the destructive distillation of acetate of lead. When carefully purified, it has a peculiar spirituous odour, is limpid, and very inflammable; its specific gravity is 0·792, and it boils at 132°. It consists of 3 car. + 3 h. + ox. Hence 1 equivalent of acetic acid (4 car. + 3 h. + 3 ox.) corresponds to 1 equivalent of pyroacetic spirit and 1 of carbonic acid: hence dry acetate of baryta is resolved by heat into carbonate of baryta and pyroacetic spirit. The term *acetone* is now commonly applied to this compound.

PYRO-ACIDS. (Gr. πυρ.) The prefix *pyro* is usually applied to the products which are obtained by subjecting certain organic acids to heat. The acids are thus modified, and give rise to distinct classes of salts. Thus we have the pyrogallic, pyromalic, pyrotartaric acids, &c.

PY'ROCHLORE. (Gr. πυρ, and χλωρος, *green*.) A name given by Werner to the octoedral ore of titanium.

PYROLI'GNEOUS ACID. (Gr. πυρ, and Lat. lignum, *wood*.) This term is generally applied to the *acid liquor* which passes over along with tar and gaseous products when wood is subjected to destructive distillation. This acid liquor is an impure vinegar, from which acetic acid is obtained as follows: — The pyroligneous acid, freed from tar, is saturated with chalk or powdered slaked lime, filtered, and evaporated, by which an impure acetate of lime is obtained; this is gently heated, so as to destroy part of its empyreumatic matter without decomposing the acetic acid; it is then mixed with sulphate of soda, which yields, by double decomposition, sulphate of lime and acetate of soda; the acetate of soda is filtered off the sulphate of lime, evaporated, heated, and redissolved and crystallized. In this way a pure crystallized acetate of soda is by proper management obtained, which is mixed in a retort or still with a proper proportion of sulphuric acid, and a gentle heat applied, which causes the strong acetic acid to distil over, and sulphate of soda remains behind. This acetic acid is in a high state of concentration; it is lowered by the addition of water, and if intended for the table or for domestic use, as a substitute for other forms of vinegar, it is usually coloured with a little burned sugar. The charcoal which is the residue of this distillation of wood is of an excellent quality; — that employed in the manufacture of gunpowder is thus prepared. This manufacture of vinegar is now carried on upon a very large scale, and the greater part of the vinegar used for domestic purposes and in the arts, in many of which it is largely consumed, is derived from this source.

PYROLIGNEOUS SPIRIT. *See* PYROXYLIC SPIRIT.

PYROLU'SITE. A mineralogical term applied by some to the common black or binoxide of manganese, from the facility with which it is resolved by heat into oxygen and a suboxide.

PY'ROMANCY. (Gr. πυρ, and μαντεια, *prophecy*.) Among the classical ancients, a species of divination by means of the fire of the sacrifice; in which, if the flames immediately took hold of and consumed the victims, or if they were bright and pure, or if the sparks rose upward in a pyramidal form, success was said to be indicated. If the contrary took place, misfortunes were said to be presaged.

PYRO'METER. (Gr. πυρ, and μετρον, *measure*.)

An instrument for measuring the degrees of heat. According to this definition, the pyrometer is synonymous with thermometer; but though the two terms are sometimes applied indifferently to the same instrument, the term *pyrometer* is generally understood to denote either an instrument intended to measure higher temperatures than can be measured by the ordinary thermometer, or an instrument for comparing the expansions of different metals.

Various contrivances have been employed for the above purposes. Musschenbroek, the original inventor of the pyrometer, adopted the following method:—A prismatic rod (about six inches long) of the metal under trial being attached at one extremity to an immoveable obstacle, and heated by lamps, the other end is necessarily pushed forward; and this being fastened to the end of a rack playing into a pinion, communicates a revolving motion to an axle to which a train of wheel-work is attached, whereby the minutest expansion of the heated bar is rendered sensible, and measured by an index on a dial. The principle of this apparatus is sufficiently simple; but the uncertainty attending the motion of so many loosely connected wheels and pinions must have rendered its indications of little value; and the method is liable to a still more serious objection, namely, that the temperature communicated to the bar by the lamps is entirely unknown. Desaguliers, and afterwards Ellicott, made several improvements in the construction of the instrument, tending to give it a more equable motion and to increase its delicacy. Graham substituted a micrometer screw for the wheels and levers that had formerly been employed; and on this principle Mr. Smeaton contrived an ingenious apparatus, which is described in the *Phil. Trans.*, vol. xlviii

Various other forms of the pyrometer have been proposed, to render it better adapted for the measurement of expansion by heat; among which the most perfect perhaps are those contrived by Ferguson, De Luc, and particularly that employed by Ramsden for determining the expansion of the glass rods used in measuring the base on Hounslow Heath for General Roy's survey. (See *Phil. Trans.*, 1785.)

For ascertaining the temperatures of furnaces, and other very high temperatures, the pyrometers now described are inapplicable. In order to remedy this deficiency, Wedgwood availed himself of the property which clay possesses of contracting by heat, and remaining afterwards in that state of contraction. He found, by repeated trials, that fine porcelain clay contracted uniformly with the degree of heat applied to it; accordingly, by measuring the dimensions of a cylindrical piece of this substance (which may be done with great accuracy, by observing the depth to which it will sink between two scales of metal inclined to each other under a small angle), and the subjecting it to the heat of a furnace, and applying the scale again to it when cold, an indication of the degree of heat to which it has been subjected is given by the amount of its contraction. Wedgwood divided his scale into 240°; and, in order to compare it with that of Fahrenheit's thermometer, made use of a piece of fine silver fitted to the same mould as the pyrometric pieces of clay. Having determined the expansion of the silver between 50° and 212° of Fahrenheit's scale, the silver and clay were subjected to the same heat; and, by a comparison of the expansion of the one with the contraction of the other, he estimated that each degree of his scale was equal to 130° of Fahrenheit's. He also estimated that the zero of his scale corresponded with 1077·5° of Fahr.; and from these data comparative tables of the two scales are formed. The objections to this method are, that as clay is a heterogeneous mixture, it is not very probable (and there are no means of ascertaining the fact) that its contractions are equal at different temperatures; and that different portions of clay possess different degrees of contractibility. It was also surmised that a long or frequent exposure to inferior degrees of heat will cause it to contract, even after it has undergone the action of a high temperature; but this appears to have been disproved. (*Phil. Trans.*, 1782, 1784, 1786.)

Guyton Morveau invented a platina pyrometer as a substitute for Wedgwood's. In a solid plate of highly baked porcelain a groove was cut containing a flat bar of platina, an inch and three quarters in length, two tenths of an inch broad, and one tenth of an inch thick. One end of the bar abuts against the bottom of the groove, the other presses against the short arm of a bent lever, of which the long arm, moving on a pivot, becomes the index of the instrument, and marks the degrees on a scale fixed to the porcelain. With this instrument he made numerous experiments, the general result of which proved that Wedgwood had assigned by far too high a temperature for the degrees of his scale. (*Annales de Chimie*, tom. xlvi.; *Nicholson's Journal*, vol. vi.)

A pyrometer, invented by Professor Daniell, is described in the eleventh volume of *Brande's Quarterly Journal*. The part on which the heat acts consists of a rod or wire of platina, about ten inches in length, and about a seventh of an inch in diameter, placed within a tube of black lead ware, and having one end fixed at the bottom of the tube: to the other end is attached a fine wire of platina, which, after passing two or three times round the axis of a wheel, is fastened to a spring by which it is always preserved at the same degree of tension. The teeth of the wheel play into a pinion, the axis of which carries an index, whose revolution shows, on a greatly magnified scale, the expansion and contraction of the platina rod. With this instrument experiments were made to determine the fusing points of the different metals; the results agreed nearly with those of Morveau, but differed widely from those of Wedgwood. Mr. Daniell subsequently made great improvements upon this apparatus, or rather invented a second pyrometer, which is described in the *Phil. Trans.* for 1830, and the *Phil. Magazine* for 1831 and 1832.

For Mr. Prinsep's method of determining high temperatures from the fusing points of pure metals and different metallic alloys, see *Phil. Trans.*, 1828; or *Phil. Mag.*, new series, vol. iii. (See *Library of Useful Knowledge; Gregory's Mechanics; Encyc. Brit.*)

PYROMO'RPHITE. (Gr. πυρ, and μορφη, *form.*) Native phosphate of lead. When heated before the blowpipe, it fuses into a globule, which assumes a polyhedral crystalline form as it cools.

PY'ROPE. (Gr. πυρ, and ωψ, *the eye.*) A fiery or brilliant red garnet.

PYRO'PHORUS. (Gr. πυρ, and φερω, *I bear.*) A substance which spontaneously takes fire when exposed to air. *Homberg's* pyrophorus is made by mixing equal weights of alum and brown sugar, and stirring the mixture over the fire in an iron ladle till quite dry; it is then put into an earthen or coated glass bottle, and heated red-hot so long as a flame appears at the mouth; it is then removed, carefully stopped, and suffered to cool. The black powder which it contains becomes glowing hot when exposed for a few minutes to the air: the experiment succeeds best in a damp state of the atmosphere, and the ignition is frequently accelerated by breathing upon the powder. A mixture of 3 parts of lampblack, 4 of dried alum, and 8 of carbonate of potassa, may be substituted for the above, and calcined in the same way: 27 parts of sulphate of potassa and 15 of calcined lampblack, heated to redness in a crucible, and then carefully preserved out of contact of air, also yields a good pyrophorus.

It appears from Gay Lussac's experiments that the essential ingredient in pyrophorus is sulphuret of potassium; the charcoal and alumina only act by being interposed between its particles; but, when the mass once kindles, the charcoal takes fire and prolongs the combustion. An excellent pyrophorus is afforded by heating tartrate of lead red-hot in a glass tube, in which it may afterwards be hermetically sealed. When the tube is broken, and the black powder within it shaken out through the air, it burns with the emission of a dense smoke of oxide of lead. This curiously shows the spontaneous inflammability of minutely divided lead.

PYRO'RTHITE. (Gr. πυρ, and ορθος, *straight.*) A mineral resembling *orthite*, but differently affected by heat.

PYRO'SIS. (Gr. πυροω, *I burn.*) A disease of the stomach, attended by a burning sensation, and the throwing up of a quantity of saline and sour fluid; it is sometimes called *water brash* and *black water*: it is a variety of *heartburn.*

PYRO'SMALITE. (Gr. πυρ, οσμη, *odour*, and λιθος, *a stone.*) A native submuriate of iron, which, when heated, exhales the odour of chlorine.

PY'ROSOME, *Pyrosoma.* (Gr. πυρ, and σωμα, *a body.*) The generic name of certain compound Ascidians, remarkable for the brilliant phosphoric luminosity which they emit.

PY'ROTE'CHNY (Gr. πυρ, and τεχνη, *art*), signifies, in its widest sense, the art or science which teaches the management and application of fire to certain operations; but it is most usually restricted to those articles and instruments manufactured for amusement, or for grand public occasions. The origin of artificial fireworks is lost in obscurity. They were in general use in China long before their introduction to Europe, which is comparatively of recent date. The finest inventions of this kind are due to the celebrated Ruggieri, father and son, who executed in Rome and Paris, and the principal capitals of Europe, the most brilliant fire-works that were ever seen.

Fire-works are divided into three classes:—1. Those to be set off upon the ground; 2. Those which are shot up into the air; and 3. Those which act upon or under water.

The three prime materials of this art are, nitre, sulphur, and charcoal, along with filings of iron, steel, copper, zinc, and resin, camphor, lycopodium, &c. Gunpowder is used either in grain, half crushed, or finely ground, for different purposes. The longer the iron filings, the brighter red and white sparks they give; those being preferred which are made with a very coarse

file, and quite free from rust. Steel filings and cast-iron borings contain carbon, and afford a more brilliant fire, with wavy radiations. Copper filings give a greenish tint to flame, those of zinc a fine blue colour; the sulphuret of antimony gives a less greenish blue than zinc, but with much smoke; amber affords a yellow fire, as well as colophony and common salt; but the last must be very dry. Lampblack produces a very red colour with gunpowder, and a pink with nitre in excess. It serves for making golden showers. The yellow sand, or glistening mica, communicates to fire-works golden radiations. Verdigris imparts a pale green; sulphate of copper and sal-ammoniac, a palm-tree green. Camphor yields a very white flame and aromatic fumes, which mask the bad smell of other substances. Benzoin and storax are used also on account of their agreeable odour. Lycopodium burns with a rose colour and a magnificent flame; but it is principally employed in theatres to represent lightning, or to charge the torch of a fury. (See, for full information as to the various processes adopted in the construction of fire-works, *Ure's Dict. of Arts, &c.*, art. "Fire-works.")

PY'ROXENE. (Gr πυρ, and ξενος, *a stranger.*) The *augite*, supposed to have pre-existed in the volcanic minerals containing it, and not to have been formed by fire.

PYROXY'LIC SPIRIT. (Gr. πυρ, and ξυλον, *wood.*) This is one of the products of the destructive distillation of wood. Its specific gravity when rectified is 0·804: it boils at 150°; it burns with a blue flame, and may be used as a substitute for alcohol in lamps, for which purpose it is often sold under the name of naphtha. It is assumed to be the hydrate of a peculiar hydrocarbon which chemists have designated by the term *methylene* (from μεθυ, *wine*, and υλη, *wood*).

PY'RRHIC DANCE, called by the Romans Pyrrhica Saltatio. A species of warlike dance, said to have been invented by Pyrrhus to grace the funeral of his father Achilles, though this point is involved in obscurity. This dance consisted chiefly in such an adroit and nimble turning of the body as represented an attempt to avoid the strokes of an enemy in battle, and the motions necessary to perform it were looked upon as a kind of training for the field of battle. This dance is supposed to be described by Homer as engraved on the shield of Achilles. Lord Byron describes the Suliotes as still performing this dance (*Childe Harold*); and in the famous ode on the aspirations of Greece after liberty, he exclaims:—

> "You have the Pyrrhic dance as yet,
> Where is the Pyrrhic phalanx gone?
> Of two such lessons why forget
> The nobler and the manlier one?"

PY'RRHONISTS. The followers of Pyrrho, a philosopher of Elis, and disciple of Anaxarchus, who flourished about 300 B.C. Their tenets, which have come to us only through the reports of unfriendly writers, are said to have been so absurdly sceptical, that the Pyrrhonists would not put even as much confidence in the senses as was necessary for the preservation of their existence; but this seems partly refuted by the age at which Pyrrho himself died, which was 90 years. There is a summary of the doctrines of Pyrrhonism in the 2d vol. of the historical part of the *Encyc. Metropolitana*. *See* SCEPTICISM.

PYTHAGORE'ANS. The followers of Pythagoras, a native of Samos, born B.C. 570; said to have been the first Greek who assumed the title of a philosopher. Pythagoras, after travelling through Egypt and the East in search of instruction, finally fixed his abode at Crotona, one of the Dorian colonies in the south of Italy. He here attached to himself a large number of youths of noble descent, whom he formed into a secret fraternity for religious and political as well as philosophical purposes; and by their assistance produced many beneficial changes in the institutions of Croton and the other Græco-Italian cities. Of the strictly philosophical tenets of the Pythagoreans very imperfect records are preserved. Many of the doctrines ordinarily imputed to them are evidently the fabrication of the later Pythagoreans, a class of visionaries who lived during the decline of the Roman empire. The fragments of Philolaus, apparently a genuine follower of Pythagoras, have been collected by Boeckh; but these, combined with what accounts we can glean from Plato, Aristotle, and others, are far from being sufficient to give us the information necessary for a clear understanding of this very singular system. One point is sufficiently evident, that the Pythagoreans were the greatest mathematicians of their time, and that they sought in the study of mathematical relations that solution of the principal philosophical problems for which their contemporaries, the Ionic and Eleatic philosophers, sought, the first in physical, the others in ontological hypotheses. Bearing this peculiarity distinctly in mind, the student of the history of philosophy will be prepared for much in the Pythagorean doctrine which would otherwise seem capricious and unintelligible. To reduce the phenomena presented to the senses to harmony with the laws of reason is the first endeavour of philosophical thinkers: to determine its own limits, and the necessary laws of its operation, is among the last of the problems of which the reason enters on the solution. The relations of space and quantity, as they are the most obvious, are also the most distinct and definite forms, in which the laws of the outward world can present themselves to this faculty. We cannot, therefore, feel surprise when we discover in the early mathematicians that error which has more or less prevailed among all great mathematicians who meddled with philosophy—the error of striving to enlarge the domain of their favourite science beyond its legitimate bounds. Precisely as the atomic philosophers have endeavoured to explain all things by a diversity in the figure of their ultimate parts, the Pythagoreans seemed to have found, in the number and proportions of those parts, the true essence of the things themselves. Having proceeded thus far, they went a step farther. They perceived that the universe and its parts are obedient to certain laws, and that these laws can be expressed by numbers. By a mistake prevalent during every period of speculation, they mistook the necessary conditions of a thing's subsistence for the essence of that thing itself; and at once pronounced that numerical relations were not merely all that could be understood in outward phenomena, but were, in fact, all that was real in them. Units of number grew gradually into points in space, and these into material atoms. To every order of existence, even to many abstract conceptions, a distinct number was assigned. God is represented as the original unity; the human soul, the earth, the planets, the animal creation, have each their own peculiar arithmetical essence; as have also the abstractions *justice*, *opportunity* (καιρός), *opinion*, &c. In many of these *numbers*, it is not difficult to imagine a symbolical meaning; but how far any such meaning was contemplated by the Pythagoreans must remain matter of doubt.

The outlines of a dualistic scheme are discernible in a singular table of opposites (συστοιχία), preserved to us by Aristotle, in which the two principles of the universe are successively represented under the form of limit and the unlimited, odd and even, one and many, right and left, male and female, still and moved, straight and curved, light and darkness, good and evil, square and oblong.

But it would far exceed our limits to enumerate the various fanciful disguises under which the Pythagoreans voluntarily or involuntarily concealed the result of their meditations. Their moral system is more intelligible, being founded, as the tone of their general doctrines would lead us to anticipate, on the ideas of law and harmony. Every state, and every member of a state, is to exhibit, each in his degree, a miniature resemblance of the universal constitution of the world. This essentially Greek idea they sought to realize in themselvess by a long course of propædeutic discipline, in which music plays a conspicuous part. That the Pythagoreans were strongly influenced by their doctrines, is sufficiently apparent in the length of time during which their brotherhood continued. Philolaus, Lysis, Cleinias, Eurythes, and Archytes, in all probability genuine Pythagoreans, were contemporaries of Plato and Socrates. (See *Thirlwall's Hist. of Greece*, vol. ii. c. 12.; *Ritter's Hist. of Philosophy*, b. iv.; *Boeckh's Philolaus*, &c.)

The doctrine of *metempsychosis*, or the transmigration of souls through different orders of animal existence, is the main feature by which the Pythagorean philosophy is popularly known. It is, however, by no means certain that the genuine Pythagoreans held this doctrine in a literal sense. It may have been only a mythical way of communicating their belief in the individuality and *post mortem* duration of the soul.

PY'THIAN GAMES. One of the four great national festivals of Greece, celebrated every fifth year in honour of Apollo, near Delphi. Their institution is variously referred to Amphictyon, son of Deucalion, founder of the council of Amphictyons, and Diomed, son of Tydeus; but the most common legend is that they were founded by Apollo himself, after he had overcome the dragon Python. The contests were the same as those at Olympia, and the victors were rewarded with apples and garlands of laurel. As is well known, the priestess who delivered the oracle at Delphi was called Pythia. *See* DELPHI.

PY'THON. (Gr. πυθων.) The name of a genus of large non-venomous Ophidian reptiles, having anal hooks, and a double series of sub-caudal scutæ.

PYX. The name given to the box in which the host is kept by the Roman Catholic priesthood.

PYXI'DIUM. (Gr. πυξις, *a small box.*) A fruit which divides circularly into a lower and upper half, of which the latter acts as a kind of lid.

PY'XIS NAUTICA. The Mariner's Compass. A constellation of the southern hemisphere, formed by Lacaille.

PYX, TRIAL OF. *See* COINAGE.

Q.

Q. (Fr. queue, *a tail;* its form being that of O with a tail.) In all the languages in which it is used it is invariably followed by *u*. Q is used as an abbreviation for *question;* Qy. for *query;* Q. E. D. for *quod erat demonstrandum*, which was to be demonstrated, &c.

QUADRAGE'SIMA. (Lat. *fortieth.*) In the Calendar, a term applied to the time of Lent, because it consists of about forty days. *Quadragesima* Sunday is the first Sunday in Lent, and about the fortieth day before Easter.

QUADRA'NGLE. In Geometry, a plane figure having four angles, and consequently four sides.

QUA'DRANS. A division of the Roman *as*, consisting of one fourth of it, or three ounces when the *as* was of its full weight. (*See* As, Teruncius.) A farthing. Before Edward I. the smallest coin was a penny or starling. It was marked with a cross, so as to admit of being quartered; but, to avoid unfair cutting, halfpence and farthings were coined in the above reign.

QUA'DRANT. In Geometry, the fourth part of a circle; an arc of 90 degrees.

Quadrant is also a mathematical instrument, formerly much used in astronomy and navigation. The instrument is variously contrived and fitted up, according to the purpose for which it is intended; but it consists essentially of a limb or arch of a circle equal to the fourth of the circumference, and divided into 90°, with subdivisions. The mural quadrant is of considerable size (6 or 8 feet radius, for example), the axis of which moves in a wall or solid piece of masonry. Ptolemy, in the *Almagest*, describes a quadrant with which he determined the obliquity of the ecliptic. Tycho Brahe had a large mural quadrant for observing altitudes, and others which revolved on a vertical axis for measuring azimuths. Picart, in his measurement of the earth, used a quadrant for his terrestrial angles. In 1725 a mural quadrant, by Graham, was erected in the Royal Observatory at Greenwich, which, in 1750, was replaced by Bird's quadrant, with which Bradley made his celebrated observations. The quadrant has, however, of late years been entirely superseded by the *mural circle;* it having been found that the circle, on account of the symmetry of its form, and the advantage which it possesses of allowing the readings to be made at different parts of the limb, is an instrument much more to be relied on. (*See* Mural Circle.) *Hadley's quadrant*, in its principle and application, is the same as the *sextant*, by which it has been superseded. (*See* Sextant.) For further information respecting the quadrant, see Lalande, *Astronomie*, s. 2311.; *Vince's Practical Astronomy; Pearson's Practical Astronomy;* and the *Penny Cyclopedia.*

Quadrant, in Gunnery, or the *gunner's square*, is an instrument used for elevating and pointing cannon, mortars, &c. It consists of two rectangular branches of wood or brass, having a quadrantal arch between them, divided into 90°, and furnished with a thread and plummet. One of the branches being placed in the mouth of the piece, the degree intersected by the thread on the limb shows the elevation.

QUADRAN'TAL TRIANGLE, in Trigonometry, is a spherical triangle which has one side equal to a quarter of a circle, or 90°.

QUA'DRANT OF ALTITUDE. An appendix to an artificial globe, consisting of a thin pliable slip of brass, which is applied to the globe, and used as a scale for measuring the distances between points in degrees. It is graduated into 90°, the degrees being of the same length as those on one of the great circles of the globe. At the end where the division terminates a nut is rivetted on, and furnished with a screw, by which it is attached to the brass meridian of the globe at any point. This point being placed in the zenith, and the quadrant applied to the globe, its zero coincides with the horizon, and consequently the altitude of any point along its graduated edge is indicated by the corresponding division.

QUADRA'TIC EQUATION, in Algebra, is an equation of the second degree, or one which involves the second power, or square, of the unknown quantity.

Quadratic equations are of two kinds, *incomplete* and *complete*. The incomplete equation is that which contains only terms affected by the square, and not by the simple power of the unknown quantity. It is also called an *equation of two terms*, because, by means of proper reductions of the known quantities, it may always be put under the form $a x^2 = b$; or a *pure* quadratic, because, on dividing by the coefficient of x^2, it contains only the square of the unknown quantity in one term, or is of the form $x^2 = c$.

The *complete* quadratic equation consists of three terms, containing the square of the unknown quantity in one, the simple power in another, and the known quantities in a third. It is also called an *affected* quadratic, and its general form is $a x^2 + b x + c = 0$.

When the proposed equation consists of only two terms, the method of finding the value of the unknown quantity is obvious. Let the equation after reduction be $x^2 = p$, then $x = \sqrt{p}$. Now, if p be a number, its square root, which is the value of x, can either be found exactly, or to any required degree of approximation; and if p be an algebraic quantity, its square root will be found either exactly or approximately by the ordinary methods of extraction. There is, however, a circumstance respecting the sign of the root which must be attended to. The root of any quantity may be either positive or negative, because the square of $+a$ and of $-a$ is equally a^2; whence $\sqrt{a^2} = \pm a$, and the equation $x^2 = p$ gives two values of x, namely, $x = +\sqrt{p}$, and $x = -\sqrt{p}$.

As the square of any quantity, whatever be its sign, is always positive, it follows that a negative quantity can never be formed by the multiplication of any real quantity into itself, and hence an equation of the form $x^2 = -p$ can have no real root. When such an equation occurs in the solution of a problem in which only real quantities are concerned, it shows that some contradiction is involved, either in the data, or in the reasoning by which that result has been produced.

A complete quadratic equation is always reducible to the form $x^2 \pm a x = \pm b$; and in order to deduce from it the value of x, it is necessary to add some known quantity to both sides by which the first will be rendered an exact square. The square of the binomial $x + u$, is $x^2 + 2 u x + u^2$; on comparing this with $x^2 + a x$, it is evident that if we suppose $a = 2 u$, or $u = \frac{1}{2} a$, and consequently $u^2 = \frac{1}{4} a^2$, the quantities $x^2 + 2 u x + u^2$ and $x^2 + a x + \frac{1}{4} a^2$ will be equal; and therefore, since $x^2 + 2 u x + u^2$ is the square of $x + u$, so $x^2 + a x + \frac{1}{4} a^2$ must be the square of $x + \frac{1}{4} a^2$, which is equal to $x + u$. If, therefore, the proposed equation be $x^2 + a x = b$, let $\frac{1}{4} a^2$ be added to both sides, and it becomes $x^2 + a x + \frac{1}{4} a^2 = \frac{1}{4} a^2 + b$, which, on extracting the square root, gives $x + \frac{1}{2} a = \pm \sqrt{\frac{a^2}{4} + b}$; therefore, by transposition, $x = -\frac{1}{2} a \pm \sqrt{\frac{a^2}{4} + b}$.

In like manner, it will appear that if the proposed equation were $x^2 - a x = b$, the equation giving the value of x will be $x - \frac{a}{2} = \pm \sqrt{\frac{a^2}{4} + b}$; whence $x = \frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}$. The quantity b retains the same sign in the resolved as in the original equation.

From these considerations, the rules for the solution of quadratic equations in general follow so obviously that it is unnecessary to state them in form. The double sign, however, which appears in the root, and which shows that the unknown quantity in every quadratic equation has two distinct values, requires some further attention.

Taking an example in numbers, let the proposed equation be $x^2 + 2 x = 35$. Adding to each side the square of half the coefficient of x, or of 1, it becomes $x^2 + 2 x + 1 = 36$; whence $x + 1 = \pm 6$, and, consequently, $x = -1 \pm 6$; that is, $x = +5$, or $x = -7$. Now, if we transpose the absolute term of the proposed equation $x^2 + 2 x = 35$ to the left side, it becomes $x^2 + 2 x - 35 = 0$; and it is easy to see (and may be proved by actual multiplication), that $x^2 + 2 x - 35$ arises from the product of two factors $x - 5$ and $x + 7$; therefore $(x - 5)(x + 7) = 0$. But this last equation may be satisfied in two ways, viz. either by making $x - 5 = 0$, or by making $x + 7 = 0$. If $x - 5 = 0$, then $x = 5$; and if $x + 7 = 0$, then $x = -7$. There are two values of x, therefore, which alike satisfy the proposed equation nearly, +5 and − 7, and these are the two roots found above by the direct solution.

What has been now said in respect of the particular example is true of quadratic equations in general. Every expression of the form $x^2 + a x - b$ is decomposable into two factors, $x - p$ and $x + q$, in which p and q are quantities independent of x, and depending only on a and b. Hence the equation $x^2 + a x - 6 = 0$ is identical with the equation $(x - p)(x + q) = 0$; and this last is obviously satisfied alike by making $x - p = 0$, or by making $x + q = 0$, that is, by $x = +p$ or $x = -q$.

It follows, therefore, that every quadratic equation has necessarily two roots, and it is obvious that it can have no more than two; for if it could be supposed to have three, or any great number, then the expression $x^2 + a x - b$ would be resolvable into as many separate factors of the form $x - p$, $x - q$, $x - r$, &c. But this is evidently impossible; for the product of three such factors would necessarily contain the third power of x, or x^3, which the given equation does not. The resolution of equations into as many factors as there are roots is a

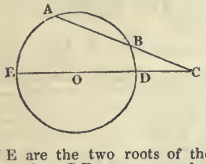
property belonging to equations of every degree. *See* EQUATIONS.

The consideration of the nature of the factors into which the proposed equation can be resolved leads to some important consequences. The hypothesis $x^2 + a x - b = (x - p)(x + q)$ gives $x^2 + a x - b = x^2 - (p - q) x - p q$; whence, since x is an indeterminate quantity, we must have $a = -(p - q)$ and $b = p q$. Now, since $+p$ and $-q$ are the two roots of the equation $x^2 + a x = b$, it is evident that $p - q$ is their sum, and $-p q$ their product; therefore, because $p - q = -a$, the sum of the two roots of any quadratic $x^2 + a x = b$ is equal to the coefficient of the second term, having its sign changed; and their product is equal to the absolute number or term which does not contain x, having its sign also changed.

The roots of quadratic equations may be exhibited by a geometrical construction. All quadratics belong to one of the four forms,

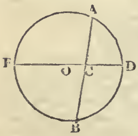
$$x^2 + a x = b c, \quad x^2 - a x = b c,$$
$$x^2 + a x = -b c, \quad x^2 - a x = -b c.$$

Now to construct the first form, let a circle be described on a diameter $= a$, or radius $= \frac{1}{2} a$: in the circle inflect a straight line, $A B = b - c$, and produce it to C, so that $A C = b$, and consequently $B C = c$; and draw C D E through the centre O, meeting the circle in D and E; then C D and C E are the two roots of the equation. For let $C D = x$, then $C E = x + a$, and the rectangle $C D \cdot C E = x(x + a) = x^2 + a x$. But by construction $C A \cdot C B = b c$, and by the property of the circle $C D \cdot C E = C A \cdot C B$; therefore, $x^2 + a x = b c$, which was the equation given.



To construct the second form, namely, $x^2 - a x = b c$, let $C E = x$; then $C D = x - a$, and, consequently, $C E \cdot C D = x(x - a) = x^2 - a x$; but, as before, $C E \cdot C D = C A \cdot C B = b c$; therefore $x^2 - a x = b c$, and the roots of the equation are C E and C D. In these two cases, if $b - c = 0$, the straight line C B A becomes a tangent to the circle; and if $b - c$ be greater than a, another line may be taken which is a mean proportional between b and c, and which will be the tangent to the circle, so that the construction is possible in all cases.

To construct the fourth form, $x^2 - a x = -b c$, let a circle be described with the radius $\frac{1}{2} a$ as before, and inflect in it a straight line $A B = b + c$; take $A C = b$, and through C and the centre O draw the diameter E D; then E C and C D are the two roots of the equation or values of x. For, since $E D = a$, if $E C = x$, then $C D = a - x$, and therefore $E C \cdot C D = x(a - x) = a x - x^2$. But $E C \cdot C D = A C \cdot C B = b c$; therefore $a x - x^2 = b c$; or $x^2 - a x = -b c$. The same construction gives the third form, $x^2 + a x = -b c$; but the two roots are in this case both negative, namely, $-E C$ and $-C D$.

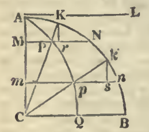


Hence it follows that every geometrical problem producing a quadratic equation can be constructed by means of a circle and straight lines; and, reciprocally, all problems respecting circles and straight lines may be resolved algebraically by means of quadratic equations.

QUADRA'TO, or QUA'DRO. (It.) In Music, a name given to the note B in the natural or diatonic scale, marked thus ♮, being a semitone minor higher than B mol or ♭.

QUADRA'TRIX. In Geometry, a transcendal curve, by means of which the quadrature of curvilinear spaces can be determined mechanically. The best known of these curves is the *Quadratrix of Dinostratus*, so called from its reputed inventor, a brother of Menechmus and disciple of Plato. This curve is generated as follows:—

In the circular quadrant C A B, suppose the radius C A to revolve uniformly about C, passing through the different positions C K, C k, &c., till it arrives at the position C B; and that during the same time a line A L, at right angles to C A, moves parallel to itself with a uniform motion from the position A L, passing through the different positions M N, m n, &c., and arriving at C B at the same instant that C K coincides with C B; then the continual intersection of the revolving radius and the parallel line will trace the quadratrix A P Q.



From this mode of describing the curve, it is easy to see how it may be applied to divide an angle into any number of equal parts. Let it be required, for example, to trisect the angle A C k. Having applied the quadratrix to C A, take A M equal to a third of A m, and through M draw M N perpendicular to A C, meeting the curve in P; join C P, and the angle A C P is equal to one third of A C k; for by the nature of the quadratrix A M : A m : : A K : A k.

The application of this curve to the quadrature of the circle depends on the property that the line C Q is a third proportional to the quadrantal arc A B, and the radius. Hence the arc $A B = \frac{C B^2}{C Q}$, and consequently the area of the quadrant $C A B = \frac{C B^3}{2 C Q}$.

If the quadratrix be continued beyond A, without the circle, it will consist of a series of infinite hyperbolic branches, cutting the axis C A produced, in points which are separated from each other by a space equal to 2 A C.

Other curves may be formed in a similar manner, by which the quadrature of the circle would be obtained. Thus, instead of supposing the lines M N, m n to be intersected by the radiants C K, C k, we may suppose straight lines drawn from K k parallel to A C, intersecting M N, m n in r and s; these intersections form a different curve, which is called the *Quadratrix of Tschirnhausen*.

Let $A M = x$, $M P = y$, and $A C = a$; then, since $x : a : : A K : A B$, or $\frac{1}{2}\pi$, we have $A K = \frac{\pi x}{2 a}$. Hence the equation of the quadratrix of Dinostratus is $y = (a - x) \tan. \frac{\pi x}{2 a}$; and that of the quadratrix of Tschirnhausen $y = a \sin. \frac{\pi x}{2 a}$. (Montucla, *Histoire des Mathematiques; Peacock's Collection of Examples; Leslie's Geometry of Curve Lines.*)

QUA'DRATURE, in Astronomy, denotes the position of the moon when she is 90° from the sun, or at one of the two points of her orbit equally distant from the conjunction and opposition.

QUADRATURE, in Geometry, signifies the determination of the area of a curve, or finding an equal square. The differential element of the area of a curve referred to rectangular co-ordinates is $y\,d\,x$; and since y is given in terms of x by the equation of the curve of which the area is proposed to be found, the problem of quadratures in general reduces itself to the integration of the differential $X\,d\,x$, in which X is an algebraic function of x and known quantities. In the applications of the higher geometry, a problem is conceived to be resolved when it is reduced to quadratures; that is, when the variable quantities have been separated, and its solution been made to depend on finding the values of one or more integrals of the form $\int X\,d\,x$. In the case of some curves, parabolas, for example, of different orders, expressed by the equation $y^m = a x^n$, the integral is found in finite terms; in regard to other curves, the circle, for example, it can be represented by a converging series; but it frequently happens, especially in the applications to physical astronomy, that the expression represented by X is too complicated to allow of the integral $\int X\,d\,x$ being found by a converging series; and when this occurs, the only thing that can be done is to find values of it for particular cases only, that is to say, for portions of the area corresponding to values of x, taken within certain limits. The method of quadratures accordingly forms an important branch of the Integral Calculus.

The *quadrature of the circle* is a problem of great celebrity in the history of mathematical science. The whole circular area being equal to the rectangle under the radius, and a straight line equal to half the circumference, the quadrature would be obtained if the length of the circumference were assigned; and hence the particular object aimed at in attempting to square the circle is the determination of the ratio of the circumference to the diameter. This ratio can only be expressed by infinite series, of which many have been given that converge with great rapidity. *See* CIRCLE.

It is necessary to make a distinction between the *definite* and the *indefinite* quadrature. The definite quadrature would be that which would give either the area of the whole circle, or of some particular portion of it, without giving that of every other portion; the indefinite quadrature would give the area of any sector whatever, or the length of any arc which could be assigned. James Gregory undertook to demonstrate that the definite quadrature is impossible; Huygens, however, objected to his reasoning; and the opinion of geometers seems to be, that no satisfactory demonstration has yet been given of the absolute impossibility of solving the problem. It has indeed been proved by Lambert and Legendre that the ratio of the circumference to the diameter, and its square, are irrational numbers. But irrational quantities may be

susceptible of geometrical construction; and if a straight line equal to the circumference of a circle having a given radius could be constructed geometrically, the quadrature of the circle would be accomplished, although the length of the line could not be expressed by a finite number. With regard to the indefinite quadrature, Newton has demonstrated in the *Principia* (though in a manner not altogether unobjectionable) that no curve which returns into itself, like the circle or ellipse, is susceptible of it.

Numerous pretenders to the discovery of the quadrature of the circle have appeared at various times, and occasionally present themselves even at the present day. They are only to be found among those who have an imperfect knowledge of the principles of geometry; and when their reasoning happens to be intelligible, their paralogisms are in general easily detected. With a view to discourage the futile attempts so frequently made on this and similar subjects, the Academy of Sciences of Paris, in 1775, publicly announced, that it would not examine in future any paper pretending to the quadrature of the circle, the trisection of an angle, the duplication of the cube, or the discovery of the perpetual motion; and shortly after the Royal Society adopted a similar resolution. For the history of this famous problem, see the third supplement to the 4th volume of Montucla.

It was stated in the article CIRCLE that the approximation to the numerical ratio of the circumference to the diameter had been computed by De Laguy to 128 places of decimals. It should have been added, that the approximation was carried by Vega to 140 figures; and Montucla mentions a MS. in the Radcliffe Library at Oxford, in which it is carried to 154 figures. Very recently (May, 1841) a paper was communicated by Mr. Rutherford of Woolwich to the Royal Society, in which the number is extended to 208 places of decimals, and which is presumed to be accurate to the last figure, the computations having been actually carried to 210 figures.

QUA'DRICORNS, *Quadricornia.* (Lat. quatuor, *four*, and cornu, *a horn.*) The name of a family of Apterous insects, comprehending those which have four antennæ. A species of antelope with four horns is called *Antilope quadricornis*.

QUA'DRIFORES, *Quadrifora.* (Lat. quatuor, and foro, *I pierce.*) A name given by Latreille to a family of Sessile Cirripeds, comprehending those in which the opercular covering of the tube is composed of four valves or calcareous pieces.

QUADRI'GA. (Lat. quatuor, and jugum, *a yoke.*) In Antiquity, a car or chariot drawn by four horses, which were harnessed all abreast, and not in pairs. The quadriga is often met with on the reverse of medals, which are thence termed *nummi quadrigati*, or *victoriati*, from there being a representation of a figure of Victory holding the reins.

QUA'DRI HY'DROCA'RBON. A liquid hydrocarbon, in which 4 atoms of hydrogen and 4 of carbon are so combined and condensed as to constitute one atom of quadri hydrocarbon.

QUADRILA'TERAL. (Lat. quatuor, *four*, and latus, *a side.*) In Geometry, a plane figure contained by four straight lines. It comprehends the square parallelogram, rectangle, rhombus, rhomboid, and trapezium. The most general properties of a quadrilateral figure are the two following: — 1. The sum of the four angles is equal to four right angles; 2. The sum of the squares of the sides is equal to the sum of the squares of the two diagonals together, with four times the square of the straight line which joins the middle points of the diagonals.

QUADRILA'TERALS, *Quadrilatera.* (Lat.) The name of a tribe of crabs (Brachyurous Crustaceans), comprehending those in which the carapace or shell is more or less square-shaped.

QUADRIPE'NNATES, *Quadripennes.* (Lat. quatuor, and penna, *a wing.*) The name of a section of Anelytrous insects, including those which have four wings.

QUADRIRE'ME. (Lat. quatuor, and remus, *an oar.*) A ship of war in use among the ancient Greeks and Romans; so called because it had four banks of oars. *See* GALLEY.

QUADRISU'LCATES, *Quadrisulcata.* (Lat. quatuor, and sulcus, *a furrow.*) A name applied to those Ungulate quadrupeds in which the hoof is divided into four parts, corresponding to the four digits.

QUADRI'VIUM. (Lat.) In the language of the schools, the four lesser arts, — arithmetic, music, geometry, and astronomy. *See* TRIVIUM.

QUA'DRUM. In Music, the same as *natural*, which see.

QU'ADRUMANES, *Quadrumana.* (Lat. quatuor, *four*, and manus, *hand.*) The name of an order of Mammals, comprehending those in which the four extremities are terminated by a hand; as the ape, baboon, &c. The hinder extremities are always terminated by more perfect hands than the fore extremities, in which the thumb is sometimes wanting, or, in the South American monkeys, incapable of being opposed to the other digits.

QUA'DRUPEDS, *Quadrupedia.* (Lat. quatuor, *four;* pes, *a foot.*) All Vertebrate animals with four extremities fitted for terrestrial progression were formerly so called, the scaly reptiles being distinguished, as oviparous quadrupeds, from the hairy warm-blooded viviparous four-footed mammals. But as there are both reptiles and mammalia which have only two legs, and as those of both classes which agree in having four legs differ essentially in the important characters on which classific distinctions are now founded, the term quadruped is no longer used in a strict zoological sense as indicative of a particular group of animals.

QUA'DRUPLE. In Arithmetic, fourfold: the product of any magnitude or quantity multiplied by 4.

QUÆ'STOR. A Roman magistrate whose office it was to collect the public revenue, whence their name (from quæro, *I seek*) was derived. Two quæstors were originally chosen by the kings in the earliest times of the city; and after their expulsion the appointment remained in the hands of the consuls till the year 307 A.C., when they began to be elected by the people at the Comitia Tributa. Soon after this two more quæstors were appointed to attend the consuls in war; and from this time they might be chosen indifferently from plebeians and patricians, the former class having been previously excluded. As the Roman empire was extended over all Italy and the other countries that finally owned its sway, the number of quæstors was increased, so that one was appointed to each consul or prætor when he went to his province; and this was done generally by lot, but sometimes the superior magistrate was allowed to choose his own quæstor. The quæstorship was the first step of preferment which gave admission into the senate; but it was sometimes held by those who had been consuls. Under the emperors the office underwent many changes; Augustus deprived them of the charge of the treasury, which he imposed on the prætors, and gave them the superintendence of the public records; but the former office was restored to them by Claudius.

QUA'GGA. The name of a Solipedous quadruped, or species of *Equus*, allied to the zebra.

QUA'GMIRE. Boggy ground saturated with water to such a degree as to be more like mud than firm soil.

QUAIL. A genus of Gallinaceous birds (*Coturnix*, Cuv.), allied to the partridge, but of smaller size, with a more slender beak and shorter tail, and without red eyebrows or spurs.

QUA'KERS, or FRIENDS. A religious sect, which had its origin in England about the middle of the 17th century, and spread, by the emigration of its members, who were exposed to many restrictions and persecutions in this country, over various parts of Europe and North America. The founder of the sect was George Fox, who being equally dissatisfied with the tenets of the established church and those of the Puritans, succeeded in attaching to himself various persons who agreed with him in the view which he took of the internal operation of religion on men's hearts, conceiving it to supersede all the observances of different denominations, nor to be evidenced in any degree by them. The Quakers, therefore, reject both the sacraments; nor do they appoint any order of ministers, but consider the instruction and edification of their congregations to be the province of whatsoever person of either sex conceives himself to be impelled thereto at the time by an internal suggestion of the Spirit. Upon doctrinal points, however, they assert themselves to maintain opinions coincident with those generally received by the orthodox. Their internal affairs are managed by yearly, quarterly, and monthly meetings, of which the former in this country is held in London, and embraces representatives for all the rest. A similar arrangement takes place among the females of the society, who are allowed a considerable share in the management of the affairs of their own sex.

This society is distinguished in its intercourse with the world by great seriousness of deportment, uniform soberness in dress, and generally a scrupulous avoidance of every thing which can encourage vanity and frivolity. They are all sensitively averse from all matters of ceremony, which they conceive to have their origin in flattery and deception. Their refusal to take judicial oaths used in former times to subject them to very severe penalties. Up to the accession of James II. their history is an unvaried series of persecutions; either such as they endured in common with other dissenters, or such as were peculiar to themselves in consequence of their refusal to pay tithes and to take oaths. Under James, the severity of the penal laws was relaxed; but William III. was the first prince who enacted laws for the especial relief of the Quakers. From this time, their affirmation is received in lieu of oath in judicial proceedings; and an alteration in the method of levying tithes has been provided, by which their scruples are satisfied. (See, among other authorities respecting the Quakers, *Fox's Journal; Barclay's Apology;* and *Sewell's History of the Rise, &c. of the Quakers* (1722). The Quakers of the present day are thought to be a decreasing sect. In 1836, the number of their congregations was estimated at 396. (*Congregational*

Magazine.) They are most numerous in Yorkshire, Lancashire, Durham, Cumberland, and Essex.

QUA'KING BOG. Peat bog in a growing state, and so saturated with water that a considerable extent of surface will quake or shake, when pressed on by the foot or any other body. Such bogs are unfit for any useful purpose till they are drained.

QUA'LITY. (Lat. qualis.) In Physics, some property or affection of bodies. Sensible qualities are those which immediately affect the senses; as figure, taste, &c.

Quality, in the philosophy of Kant, the *second* category (there being four in all), comprising the notions of existence or reality, non-existence or negation, and limitation.

QUA'NTITY. (Lat. quantus, *how much.*) A property of any thing capable of being increased or diminished. Quantity is distinguished into *continued* and *discrete*. It is continued when the parts are connected together, and is then called magnitude, which is the object of geometry. It is discrete when the parts have an unconnected and independent existence, forming multitude or number, which is the object of arithmetic. The quantity of matter in any body is proportional conjointly to the magnitude and density of the body, and is measured by its absolute weight. Quantity of motion is used synonymously with *momentum*, to denote the product of the quantity of matter in the moving body by its velocity. Algebraic quantities are the expressions of indefinite numbers.

Quantity. In Prosody, the amount of time in a syllable. Syllables are either short or long; the former being the unit or smallest measure of time, the latter consisting of two times. This distinction is clearly marked in the ancient languages; in which some syllables are necessarily long or short by position, others by the nature of the vowels which they contain; and, in the Latin language, some common, or susceptible of being sounded as long or short, according to certain rules of elegance or convenience. All the metrical system of the ancient languages is founded on quantity. In most modern languages there is, strictly speaking, no quantity, as distinct from emphasis or accent; the long syllables being those which receive the arsis, the short those which receive the thesis. In the German language, however, critics have endeavoured to establish a conventional system of quantity, and thus to adapt that language to regular versification in the ancient Greek and Latin metres. *See* Rhythm, Metre.

QUA'RANTINE. (Ital. quaranto, *forty.*) A period of time of variable length, during which a vessel from certain coasts or ports, said or supposed to be infected with certain diseases, is not allowed to communicate with the shore, except under particular restrictions. A ship in quarantine carries a yellow flag at the main; and when released from this condition, she is said to obtain *pratique.* The term is derived from the Ital. quaranto, *forty*, it being generally supposed that if no infectious disease break out within 40 days or six weeks, no further danger is to be apprehended. It is universally believed that the Venetians were the first to adopt regulations for guarding against the introduction of infected persons into their ports; but there is now no civilized country in which it is not practised. (For full particulars on the history and policy of quarantines, see the *Com. Dict.*

QUA'RE IMPEDIT. In Law, a writ lying for one who has a right of advowson against a person who hinders or disturbs him in his right by presenting a clerk when the church is void.

QUART. A measure of capacity, being the fourth part of a gallon. *See* Measures.

QUA'RTAN. (Lat. quartus, *fourth.*) A species of intermittent fever or ague, which returns every fourth day. *See* Ague.

QUARTA'TION. In Metallurgy, the separation of silver from gold by means of nitric acid. To extract the whole of the silver from gold by the action of nitric acid, it is necessary that there should be at least three parts of silver to one of gold, otherwise the gold protects the silver from the action of the acid; so that, in thus separating these precious metals, it is customary, where gold greatly predominates, to add silver till it constitutes at least three fourths of the alloy.

QUA'RTER. The fourth part of any thing. As a term of weight, it denotes the fourth of a hundred weight, or 28 pounds; as a dry measure, it signifies the fourth of a chaldron.

Quarter. The after part of the ship's side. *On the quarter*, implies the bearing or position of an object seen between aft and abeam.

QUARTER DAYS. The days usually regarded in England and most Continental countries (but not in Scotland) as beginning the four quarters of the year. They are, 1. Lady Day (25th of March); 2. Midsummer Day (June 24th); 3. Michaelmas Day (Sept. 29th); and, 4. Christmas Day (Dec. 25th).

QUARTER DECK. The portion of the uppermost deck of a ship between the main and mizen masts. This is the "parade" in men-of-war.

QUA'RTERING. In Heraldry, the division of a shield by two lines, fess-wise and pale-wise, meeting in the centre of the shield. In marshalling, whenever a husband can place his wife's arms on an escutcheon of pretence (*see* Escutcheon), the children may bear them quarterly, with their own: whence arises the great variety of quarterings in the shields of some families.

QUARTER MASTER. In the Navy, a petty officer, who, besides other duties of superintendence, *cons* the ship, and attends to her steerage.

Quarter-master. In the Army, an officer whose business it is to look after the *quarters* of the soldiers, and attend to their clothing, bread, ammunition, &c. There is a quarter master attached to every regiment, whether of foot, cavalry, or artillery.

QUA'RTER ROUND. In Architecture. *See* Echinus and Ovolo.

QUA'RTERS. The stations of a ship's crew in time of action, to which they are summoned by beat of drum, or by the boatswain's pipe.

QUARTERS and QUARTERING. (Fr. quartiers.) In Architecture, the upright posts in partitions to which the laths are nailed. Quarters are either single or double; the former being sawn stuff two inches thick, and four inches broad; the latter usually sawn to a scantling four inches square, or four inches by a less width. No quarters should ever be more than fourteen inches apart. *Quartering* is a term properly applied only to an assemblage of quarters, though it is not unfrequently used to denote the quarters themselves.

QU'ARTER SESSIONS OF THE PEACE. In Law, a court held by two justices at least, one of whom must be of the quorum, quarterly, in every county; having a jurisdiction originally in matters touching the breach of the peace only, but since extended by various statutes. (*See* Justices of the Peace.) Quarter sessions in boroughs, since the Municipal Corporation Act, are held by the recorders.

QUARTER STAFF. A weapon of defence; so called from the manner of using it, one hand being placed in the middle, and the other equally between the middle and end.

QUA'RTETT. A piece of music arranged for four voices or four instruments. Of the latter the most celebrated are arranged for two violins, — a tenor violin, and a violoncello; and many of the most distinguished composers, among whom we may mention Haydn, Mozart, Beethoven, Romberg, Spohr, Ries, Onslow, &c., have not disdained to devote their talents to this species of composition. The term *quartett*, though strictly any piece in four parts, is seldom applied except to instrumental pieces.

QUA'RTILE A'SPECT, in Astrology, denotes the aspect or appearance of two planets, whose positions are at a distance of 90° on the zodiac.

QUA'RTINE. The fourth envelope of the vegetable ovulum, beginning to count from the outside.

QUARTO. A name given to books composed of sheets of paper folded into four leaves. It is abbreviated 4to.

QUARTODECIMA'NTES. In Church History, those who *imitated the Jews* in celebrating Easter on the 14th day of the paschal moon, instead of the Sunday next following, were so called, after they had been excommunicated as heretics by the councils of Nice, Constantinople, and Ephesus. *See* Easter.

QUARTZ. A German term, now universally adopted in scientific language, and commonly applied in mineralogy to the purer varieties of silica, especially to rock crystal.

QUASIMO'DO. In the Roman Catholic Calendar, the first Sunday after Easter; so called because the *Introit* for that day begins with the words "Quasi modo geniti infantes." (1 Pet. ii. 1.) It is also called Dominica in albis, as being the day on which those who had been baptized on Easter Sunday deposited their white robes in the sacristy.

QUA'SSIA. The wood of the *Quassia excelsa*, or *amaru;* a native of South America, and some of the West Indian Islands. It yields an intensely bitter infusion, which may be made with one drachm of the shavings of quassia to a pint of boiling water: of this a wine-glass-full may be taken twice a day, with or without other additions, as a tonic. It is a good vehicle for most of the metallic salts, which are not decomposed by it, as by many other bitter vegetable infusions. A strong infusion of quassia, sweetened with brown sugar, is a safe and effective poison for flies.

QUATRAI'N. (Ital. quattrino.) In Poetry, a piece consisting of four verses, the rhymes usually alternate; sometimes also, especially in French poetry, intermixed, the first and fourth, second and third, rhyming together.

QUA'VER. (Sax. cpazian.) In Music, a character, ♪, whose measure is equal to half a crotchet, or one eighth of a semibreve.

QUEEN. (Anglo-Sax. cwen, *wife.*) 1. A female sovereign; entitled queen regnant, or queen regent. She has, in Great Britain, the same power, prerogatives, &c., as a king, which is expressly declared by stat. 1 Mar.

1. st. 3. c. 1. In France, where females do not succeed to the throne, the title queen regent has been given to the mothers of kings holding sovereign authority, or a portion of it, during the minority of their sons; as Catherine de Medicis in the reign of Francis II.; Mary de Medicis, in that of Louis XIII.

2. *Queen Consort.* The wife of a king. Her rights and dignities (in England, as well as most other countries) appear to be similar in many respects to those of the "Augusta," or Piissima regina conjux divi imperatoris, in imperial Rome. The English queen, like the Roman empress, is capable of receiving a grant from her husband, or making one to him; therein differing from all other wives. She can also purchase and convey land, &c., without his concurrence; and sue and be sued alone: in short, she is looked upon in all legal proceedings as a feme sole. But, except where she enjoys specific exemptions, she is only on a footing with other subjects; and this also is according to the Roman maxim, "Augusta legibus soluta non est." By the Statute of Treasons, 25 Ed. 3., to compass or imagine the death of the king's "companion," and also to violate and defile her, is treason. The queen, if accused of treason herself, is tried by the peers of parliament; as Ann Boleyn in 28 Hen. 8. The consort of George IV. was proceeded against by the method of a bill of pains and penalties. *Queen-gold* was a duty amounting to one full tenth of the value of fines, &c. on grants by the crown, anciently due to the queen; which Charles I. purchased of his consort Henrietta, in 1635, for 10,000*l*., but which was not revived after the restoration. The queen consort has a separate household, consisting of six ladies of the bed-chamber, a chamberlain, vice-chamberlain, mistress of the robes, master of the horse, and three equerries, attorney and solicitor general, &c.

3. *Queen Dowager.* The widow of a deceased king. She continues to enjoy most of the privileges which belonged to her as queen consort. Nor did she, in ancient times, lose her dignity on remarriage; for Catherine, queen dowager of Henry V., after she had married Owen Tudor, maintained an action by the name of Catherine Queen of England. But it is held that no man can marry a queen dowager without special licence from the king, on pain of forfeiture of lands and goods, according to an act of 6 H. 6., which, however, is not printed among the statutes. The revenue of a queen dowager is settled by statute. By 1 & 2 W. 4. c. 11. his late majesty was empowered to settle 100,000*l*. per annum on his queen, to commence at his decease.

4. *Queen Mother.* A queen dowager who is also mother of the reigning sovereign.

QUEEN POST. In Architecture, an upright post in a roof for suspending the beam when the principal rafters do not meet in the ridge. *See* Roof.

QUE'RCITRON BARK. The bark of the *Quercus nigra*, or American oak; it is a highly valuable dye stuff, and is used in the production of some of the most durable yellows.

QUE'RCUS. (Lat.) This is the most important genus of trees found in the cold countries of the world, on account of its producing the various kinds of timber called oak. The species are not, however, confined to Europe, or similar latitudes, but occur abundantly in the equinoctial parts of Asia and America; they have not, however, been found south of the equator. It is usually recognized by the cup in which the acorn is seated; but in some tropical species the acorn is so small as to be buried in the cup, when the fruit nearly resembles that of the chestnut (*Castanea*). The valuable oak of Great Britain is obtained from two native species: the one *Q. pedunculata*, the long-stalked or white oak; the other *Q. sessiliflora*, the sessile-fruited or red oak. A prejudice has arisen against the timber of the latter, which, however, appears to be unfounded, as it is found to be in point of strength and durability fully equal to the other. Oak timber, however, is affected very much by soil and climate; and hence we have oak of bad quality from both our native species. What is called wainscot oak is probably the timber of *Q. sessiliflora*, grown rapidly in the dense forests of Hungary; by some persons, however, it is supposed to be furnished by an oriental species called *Q. cerris*, or the mossy-cupped. The *Esculus* of Virgil, whose acorns were eatable, appears to have been a sweet-fruited variety of *Q. sessiliflora*. Besides the species already mentioned, the *Quercus ilex*, or European oak, the *Q. suber*, or cork tree, whose bark is in such extensive use, and the *Q. ballota*, or Spanish ilex, whose acorns are sweet and eatable, are the more important species. Those from North America, although fine trees, are inferior to the oaks of England as regards their timber, and require hotter summers than we have in those islands. Oak galls are produced upon *Q. infectoria*, in the Levant, by the puncture of a cynips. The species are excessively confused by botanists; but a full popular account of this genus will be found in *Loudon's Arboretum Britannicum*. For a few popular details, see also the article Oak, in this work.

QUESTION. The application of torture to prisoners under criminal accusation, according to the law of France before the Revolution. The question was of two kinds: one, where strong evidence, but insufficient of itself to justify a condemnation to death, existed against a prisoner on a capital charge; he might then be subjected to torture to produce confession. This was termed the question préparatoire. It was abolished by an ordinance of Louis XVI. in 1780. The other, termed question préalable or définitive, was applied to the prisoner when convicted of a capital offence, in order to make him discover supposed accomplices. It was abolished by the National Assembly. The preparatory question was also of two sorts:—one, avec réserve de preuves, in which case, if the criminal did not confess under the torture, the other evidence was considered as still subsisting against him, so as to justify his condemnation to some lighter punishment; the other, sans réserve de preuves, in which case, if he persisted in his denial, he was acquitted altogether. It was at the option of the judges, according to their opinion of the amount of evidence, to decide to which of these questions the accused should be subjected. The modes of torture applied varied in France, being fixed by the several parliaments within their separate jurisdictions. Those in common use at Paris were,—the question by water, which consisted in stretching the limbs of the sufferer on a board by means of screws, and forcing him to swallow large quantities of water; and the boots, in which his legs were inclosed in wooden cases, the whole tightly compressed with ropes, and wedges driven with a mallet between the two cases. The question varied in degree, being *ordinary* or *extraordinary*, at the discretion of the judges. Children and adolescents, old men, and women with child, were excepted from torture by the French law. And, by an ordonnance of 1670, the second application of the question was forbidden in all cases.

Torture has been applied, as a mode of extorting confession, in all countries into which the principles of the civil law have been imported; although the barbarity and uncertainty of the practice were remarked upon even in the best times of Roman jurisprudence. The observations of Cicero on the subject are well known; and Ulpian, the greatest authority on the civil law, speaks even more directly. "Res est fragilis et periculosa (the torture), et quæ veritatem fallit: nam plerique patientiâ sive duritiâ tormentorem ita et tormenta contemnunt, ut exprimi eis veritas nullo modo possit; alii tantâ sunt impatientiâ ut quidvis mentiri quam pati mallent." It is, however, an important remark, that as, by the strict principles of jurisprudence, the torture was only applied in cases where there already existed a mass of evidence against the prisoner, sufficient, in ordinary judgment, to warrant his condemnation, it did in fact afford him an additional chance of escape; and that, however great its absurdity on every supposition, its barbarity rather arose from its liability to abuse than its legitimate infliction.

The practice of judicial torture was not a part of the common law of England, except in one particular case. The rack is said to have been first introduced into this country by the dukes of Exeter and Suffolk, in the minority of Henry VI.; at all events, it was then first made a common engine of discovery in state matters. It was used, on warrant from the privy council, on prisoners in the Tower of London for a long period afterwards, and more especially in the reign of Elizabeth, to enforce confessions or accusation of accomplices from recusant priests, and others suspected of being engaged in treasonable plots against her. It was probably employed in the examination of Guy Fawkes, after the detection of the Gunpowder Plot; as has been conjectured, among other reasons, from the feeble and trembling hand in which the signature of that criminal to his last confession is written, when compared with that in which he subscribed his former declarations. On the trial of Felton for the assassination of Villiers, duke of Buckingham, the judges were consulted by the privy council as to the lawfulness of the infliction of torture; and on their asserting it to be illegal, it was not applied. there is, however, reason to suppose that it was used at least in one subsequent case in the reign of Charles I. (See *Jardine on Torture*, 1837.)

The exception to which allusion has been made, by which torture was in one case recognized by the common law, is the celebrated Peine Forte et Dure. It has, indeed, been said, and was asserted by the judges in 8 Hen. 4., that this infliction was only introduced in consequence of the first statute of Westminster; but it is at least highly probable that before that period, persons refusing to plead were subjected to imprisonment and ill-treatment to induce them to do so. After that statute, the judgment appears only to have been to strait and severe confinement; nor was it until the reign of Hen. 4. that its horrible character seems to have been fully determined by law. After that time, the prisoner was remanded to the place from whence he came, laid on the ground in a dark room, and "as many weights as he can

bear, and more," laid upon him; with no sustenance except a morsel of the worst bread and a draught of the worst water, on alternate days; and so to remain until he pleaded or died; which alternative, according to the later practice, was soon decided, as the weights laid on were sufficient to cause speedy death. The peine forte et dure was not unfrequently put in practice until the beginning of the last century; and as late as the commencement of the reign of George III. the enforcing prisoners to plead by squeezing their thumbs, and other modes of torture, was a common Old Bailey practice. By 12 G. 3. c. 20. any person standing mute, or not answering directly to the arraignment, incurred conviction.

QUI′CKLIME. Pure or caustic lime. *See* LIME.

QUI′CKSILVER. *See* MERCURY.

QU′IETISM. A name generally applied to the opinions of enthusiasts, who conceive the great object of religion to be the absorption of all human sentiments and passions into devout contemplation and love of God. This idea has found its admirers and encomiasts in all ages. A sect called by this name (in Greek, Hesychastæ) existed among the religions of Mount Athos; and in the 17th century it was given in France to a peculiar class of devout persons with a tendency towards a higher spiritual devotion, which seems to have arisen, in great measure, out of a natural opposition to the hierarchal coldness and positive morality of Roman Catholic religion at that time, especially under the influence of the Jesuits. A Spanish priest, Molinos, published at Rome a work entitled *The Spiritual Guide* (1675), of which the ardent language attracted a multitude of partisans. Its leading feature was the description of the happiness of a soul reposing in perfect *quiet* on God, so as to become conscious of His presence only, and untroubled by external things. He even advanced so far as to maintain that the soul in its highest state of perfection is removed even beyond the contemplation of God himself, and is solely occupied in the passive reception of divine influences. The work of Molinos was afterwards condemned on the application of the Jesuits. Akin to the ideas of Molinos seem to have been those of the French Quietists, of whom Madame de la Motte Guyon and Fénélon are the most celebrated names The former was at one time treated as insane, on account of some strange delusions which led her to represent herself (unless she was calumniated) as the mystical woman of the Apocalypse; at another, she was admitted to the intimacy of Madame de Maintenon, and high in court favour. Fénélon praised her in his treatise *Sur la Vie Intérieure* (1691), in which many of the most dangerous tenets of Quietism were contained. The writings of the latter upon this subject were finally condemned by Innocent XII.; and the example of the archbishop in submitting to the decision, and declaring himself satisfied and convinced by the opinion of the church, has been dwelt on by pious writers as a signal triumph of a truly religious mind. The dissolute conduct of some hypocritical priests, under the pretence of inculcating the tenets and practice of Quietism, brought it eventually into disrepute more than the repeated condemnations of the head of the Roman Catholic church.

QUI′NCUNX. The Latin term properly for that disposition of five objects in which they are made to occupy the four corners and point of intersection of the diagonals of a square; but the word is extended to any number of things so arranged in lines that the members of each succeeding line stand behind the spaces between those of the preceding one. Troops were frequently drawn up in this order; which was also a favourite arrangement for plantations of vines.

QUINDE′CAGON. In Geometry, a plane figure bounded by fifteen sides. The regular quindecagon is inscribable in a circle by elementary geometry. (*Euclid*, Book iv.)

QUINDECE′MVIRI. Roman magistrates, whose duty it was to take care of the Sibylline books, and consult them on critical occasions when the senate deemed their advice necessary. They were exempted from the privilege of serving in the army, and from other offices in the city; and their priesthood, which was probably in service of Apollo, lasted for life. Their number, as their name imports, was fifteen by Sylla's appointment; but originally they had been ten, an equal number being elected from patricians and plebeians; and by Julius Cæsar they were raised to sixteen.

QU′INIA, or QUININE. An alkaline base obtained from yellow bark; the *Cinchona cordifolia*. This substance, combined with sulphuric acid, forms the *sulphate of quinia*, which is now so extensively used as a medicine, and as a substitute for the various forms of Peruvian bark. To obtain quinia, bruised yellow bark is boiled in repeated portions of water, acidulated by sulphuric acid, till all its soluble matters are extracted; a little excess of quicklime is then added to the strained decoction, and the precipitate which is formed is collected, washed, and carefully dried; it is then digested in alcohol, which takes up the quinia, and from which it may be obtained in the form of a yellowish uncrystallizable substance by careful evaporation. It is dissolved in dilute sulphuric acid, and the sulphate of quinine, or quinia, crystallizes from its concentrated solution in fine silky prisms, which effloresce on exposure to air. Sulphate of quinia is difficultly soluble in water, and intensely bitter. It is administered as a tonic and febrifuge in doses of from one to five or six grains.

QUINQUAGE′SIMA SUNDAY, in the Calendar, is the seventh Sunday before Easter, and consequently *about* the fiftieth day before that festival; whence the origin of the term.

QUINQUA′TRUS. In Roman Classical Antiquities, the feast of Minerva, which began on the 14th of the Kal. of April, and lasted five days. It is in allusion to the well-known attributes of the goddess that Juvenal makes this the season in which her youthful votaries pray for forensic success.

> Eloquium et famam Demosthenes et Ciceronis
> Incipit optare, et totis Quinquatribus optat.

QUINQUENNA′LIA, or LUDI QUINQUENNALES. In Classical Antiquity, public games celebrated every five years. They were instituted by the emperors in commemoration of different events of their respective reigns. Medals struck on these occasions have been discovered, bearing the date of the reign of Posthumus.

QUINQUERE′MIS. (Lat. quinque, *five*, and remus, *an oar*: in Greek, πεντηρης.) The name of a class of Roman war ships which were rowed by five banks of oars, whence the name is derived. The substitution of the quinquereme for the trireme, as the ordinary war vessel, gradually took place in the course of the fourth century before Christ: in the interval between the Peloponnesian and first Punic wars. The number of vessels of this large class employed in the latter is perfectly surprising. According to Polybius, the Romans lost 700 in the course of it; the Carthaginians 500. In A.U.C.498 (the year in which Regulus was sent to Africa) the Romans had 330, the Carthaginians 350: each quinquereme of the former nation carried 300 rowers and 120 soldiers, in all 140,000 men; the Carthaginians, according to the same computation, amounted to 150,000: numbers which would be scarcely credible, were they not given by so exact an author. *See* TRIREME, GALLEY.

QUIN′QUINA. Peruvian bark. The bark of various species of *Cinchona*, which see.

QUI′NSEY. (Fr. squinance.) Inflammation of the tonsils. This is common inflammatory sore-throat: it is not infectious. It begins with pain on one side of the throat, and swelling of the tonsil, attended by febrile symptoms, which sometimes run high, especially as the tumefaction advances; there is great restlessness and anxiety, and often the utmost difficulty of swallowing even liquids, and of breathing. The disease has proved fatal by producing suffocation, but it generally terminates in resolution, or suppuration: in the latter case the abscess breaks, and a good deal of pus is discharged, and the patient is at once relieved of all his urgent symptoms; but it occasionally happens that the other side of the throat becomes affected, and goes through the same stages.

QUI′NTAIN. An ancient pastime, in which a post was erected, with a cross-piece turning upon a pivot on the top of it, to one end of which a sand-bag was suspended, and at the other a board was fixed. The play consisted in riding or tilting against the board with a lance, and passing without being struck behind by the sand-bag.

QUI′NTAL. An old denomination of weight, being the same with the *hundred* weight, or equal to 112 pounds.

QUINTESSENCE. A term applied by the older chemists to alcoholic tinctures or essences, made by digestion at common temperatures or in the sun's heat.

QUI′NTILE. In Astrology, an aspect of two planets distant from each other the 5th of the zodiac, or 72°.

QUI′NTILIANS. A sect of ancient heretics; so called from Quintilia, their founder and leader. Their chief peculiarities consisted in attributing extraordinary gifts to Eve for having eaten of the tree of knowledge, and in admitting women to the sacerdotal and episcopal office.

QUI′NTINE. (Lat. quintus.) A name given in botany to the fifth or innermost envelop of the vegetable ovulum, the most external being the first or primine.

QUI′NTUPLE. In Music, a species of time, now seldom used, containing five crotchets in a bar.

QUINZAINE. In Chronology, the fourteenth day after a feast day, or the fifteenth, if the day of the feast be included. But a different rule seems to have prevailed on the Continent. (See *Sir H. Nicolas's Chronology of History*, p. 105.)

QUI PRO QUO, or QUID PRO QUO. (Lat. *one for another*.) A conventional term borrowed from the French, who use it in the sense of an error committed by mistaking one thing or person for another; especially a verbal ambiguity.

QUIRI′NUS. An Italian warlike divinity, supposed by some to be the same as Mars. When the Romans deified Romulus they called him by this name, and the festivals instituted in his honour *Quirinalia*.

QUIRK. In Architecture, a piece of ground cut off from a square plot.

QUIRKED MOULDING. In Architecture, one whose convexity is sudden, being in the form of a conic section.

QUI TAM. (Lat. *who as well.*) In Law, a penal action, in which half the penalty is given to the crown and the rest to the informer. The plaintiff describes him as A. B. "qui tam pro domino rege quam pro se ipso,"— who sues as well for the king as himself.

QUIT RENT. (Lat. quietus redditus.) In Law, a small rent payable by tenants of manors in token of subjection. *See* Rent.

QUO'DLIBET. (Lat. *what you please.*) In the language of the schoolmen, questions on general subjects within the range of their inquiries were termed *questiones quodlibeticæ*, or miscellaneous. In French the word quodlibet, or quolibet, is retained, in the sense of a slight jeu d'esprit, pun, &c. What is termed in music a "pot-pourri" was also called in Germany a *quodlibet*.

QUOIN. (Fr. *coin.*) In Architecture, the corner or internal and external angle of a building, or of any part of a building.

Quoin. In Artillery, a loose wedge of wood put below the breech of a cannon, for the purpose of adjusting its elevation.

QUO'RUM. A term derived from the words used in the Latin form of the commission issued to justices of the peace; in which the expression occurred, "quorum unum A. B. esse volumus,"—"of whom we will that A. B. be one;" thus rendering it necessary that certain individuals (said to be of the quorum) should be present at the transaction of business. Hence when in an assembly, committees, &c. it is necessary that a certain number should be present to give validity to its acts, that number is generally said to constitute a quorum.

QUO'TA. (Lat. quot, *how many.*) That part which each member of a society has to contribute or receive in making up or dividing a certain sum.

QUOTI'DIAN. (Lat. quotidianus.) That form of ague which returns daily.

QUO'TIENT (Lat. quoties, *how often*), in Arithmetic, is the result of the operation of division; and may be either a magnitude of any denomination, or an abstract number. When a magnitude of any kind is proposed to be divided into any number of parts, and the divisor is consequently an abstract number, the quotient is of the same kind with the dividend or quantity proposed to be divided; but when the dividend and divisor are both things of the same denomination, or both magnitudes of any kind, the quotient is an abstract number, and is the ratio of the one magnitude to the other.

QUO WARRANTO. In Law, a writ, filed in the Court of King's Bench by the attorney-general, or an individual in his name, calling upon the person informed against to show by what title he holds any office, franchise, or liberty. The proceedings on a writ of quo warranto presenting many difficulties, it has been superseded in modern times by what is termed an information in the nature of a quo warranto.

R.

R. One of those letters belonging to the series called liquids or semivowels. It was called the *litera canina* by the Latins, from some fancied resemblance it bears in sound to the snarling of a dog. At the commencement of English words derived from the Greek through the medium of the Latin *r* is usually followed by *h*, to represent the force of ῥ, as in *rhetoric, rhapsody;* and the same observation applies to this letter when it occurs in the middle of an English word derived from a Greek compound, as in *diarrhœa*, from δια and ῥεω. This letter is susceptible of numerous interchanges, more especially in Latin; for a complete list of which see the *Penny Cyclopedia*. As an abbreviation, R. among ourselves stands for *rex* or *regina*, and in ancient times for Roma; R. P. for *respublica*, &c. In medicinal prescriptions, R. stands for *recipe* or *take*.

RA'BBI. A Hebrew term for doctor or teacher; the termination being properly the first pronoun possessive. This word, which is frequently found in the New Testament, is in use at the present day, the rabbis being the expounders of the law, and more particularly of the Talmud or commentaries of later doctors. *See* Talmud.

RA'BDOMANCY. *See* Rhabdomancy.

RACA. An ancient Syriac word, signifying vanity or folly, and pronounced by the Jews with certain gestures of indignation. Our Saviour, in using the word (Matt. v. 22.), intimates that whoever should apply this word to his neighbour, should be condemned by the council of the sanhedrim.

RACE'ME. (Lat. racemus, *a bunch of grapes.*) In Botany, a form of inflorescence, in which the flowers are stalked along a common unbranched axis, as in the hyacinth.

RACE'MIC ACID. (Lat. racemus, *a bunch of grapes.*) An acid found, together with the tartaric acid, in the tartar obtained from certain vineyards on the Rhine. It is the *paratartaric acid* of Berzelius. It is less soluble in water than tartaric acid, and differs in the form of its crystals and in its salts; yet it appears to be *isomeric*, and to have the same equivalent with the tartaric acid.

RACHI'LLA. (Gr. ῥαχις, *a spine.*) A branch of inflorescence; the zigzag centre upon which the florets are arranged in the spikelets of grasses.

RA'CHIS. (Gr. ῥαχις.) A branch which proceeds in nearly a straight line from the base to the apex of the inflorescence of a plant. It is also applied to the petioles of the leaves of ferns.

Rachis. A term applied by Illiger and other zoologists to the vertebral column of mammals and birds.

RACHI'TIS. (Gr. ῥαχις, *the spine*, the part principally affected.) The rickets. A disease generally confined to childhood, known by a large head, protruded breast bone, flattened ribs, tumid belly, emaciated limbs, and great general debility; the bones in general, and especially the spine, are variously distorted and deficient in bony matter: the system occasionally rallies from this state as growth advances, but there is more or less deformity left. Tonics, cold bathing, regular and proper exercise, very careful nursing, and occasionally rhubarb and tonic aperients, are the principal remedies; and where particular bones are inclined to bend, attempts must be made to throw the weight off them. This disease is frequently symptomatic of a scrofulous state of the glands and viscera; the stomach and bowels are always greatly deranged; and as there appears to be a deficiency of the hardening matter of the bones, various salts of lime, and even phosphate of lime, have been prescribed: the only apparent use of some of these remedies is to render the gastric juice less acrid and acid.

RACK. (Sax. wroccan, *to strain, torment*, &c.; evidently of the same origin as the Germ. rachen, Ang. *to wreak.*) An instrument of torture formerly used in England. According to Coke (who, however, merely reports the story on traditional authority) the rack was first introduced into the Tower by the Duke of Exeter, constable of the Tower in 1447; and thence called "the Duke of Exeter's daughter." (3 *Inst.* p. 34.) Stowe, in his Chronicle, says that the duke's daughter herself invented it. The earliest mention of the use of the "rack or brake" is by Holinshed, under the year 1467. But it first became common in the reign of Henry VIII. Under that prince, the remaining Tudors, James I., and Charles I., down to 1640, the rack was a common implement of torture for prisoners confined in the Tower, and inflicted by the warrant of the council or under the sign manual. The rack consisted of an oblong frame of wood, composed of four beams, a little raised above the ground; the sufferer was fastened by the hands and feet to the corners, where two cross beams joined the longer ones, sometimes by small cords attached to each finger and toe; and the cords were twisted by means of rollers, so as to raise him from the ground, and stretch his body with extreme violence, dislocating the limbs, and, according to the Jesuit writers, who have left the most vivid representations of the sufferings of their companions under the state-persecution of Elizabeth, sometimes extending the sufferer "more than a palm beyond his usual stature!" (Jenner, *Societas Europæa*, p. 12.; see also *Jardine's Reading on the Use of Torture in England*, 1837.) The Roman *equuleus* is often translated rack by English writers; but whether the equuleus was something similar to the English engine, or a wooden *horse* (as the derivation of the word implies), or, in short, what was its form and description, antiquaries have not been able to discover. (See among other authorities the learned treatise of Magius, *De Equuleo.*)

Rack. A railed convenience formed above the manger in a stable for the reception of the hay. It should be constructed with openings at the bottom for the seed or dust to pass through.

RACK. In Machinery, a rectilinear sliding piece, having teeth cut on its edge so that they may work with those of a wheel or pinion which drives or follows the rack. The rack may be regarded as a toothed wheel whose radius is infinite.

RACK RENT. *See* Rent.

RACO'VIANS. In Eccl. History, the Unitarians of Poland are sometimes so called; from Racow, a small city of that country, where Jacobus a Sienna, its head, erected a public seminary for their church in 1600. Here the "Racovian Catechism," originally composed by Socinus, and revised by his most eminent followers, was published. (Mosheim, *Eccl. Hist.* cent. 16. sec. 3.)

RA'DIANT. In Geometry, a straight line proceeding from a given point, or fixed pole, about which it is conceived to revolve. When several radiants forming a system are constrained to revolve in such a manner that all the intersections excepting one are carried along given

straight lines or curves called *directrices*, then the remaining intersection traces a curve whose equation is of an order which is a certain determinate function of the orders of the several directrices. Thus, if all the intersections but one are carried along straight lines, the remaining one describes a conic section. The theory of the description of lines of the second order by the intersection of radiants is given by Newton in the *Principia;* and the subject is treated more generally by Maclaurin in his *Geometria Organica*, and by some recent writers in the *Annales des Mathématiques*. See also *Leslie's Geometry of Curve Lines;* Carnot, *Essai sur la Théorie des Transversales*, &c.

RA'DIANT HEAT. When a hot body is suspended in the air, a quantity of heat is emitted in all directions by its surface, passing off in right lines like radii drawn from the centre to the circumference of a circle; these rays pass freely through the air without affecting its temperature; when they impinge upon surrounding bodies, they are either *reflected*, *absorbed*, or *transmitted*. The quantity of these rays, or of *radiant heat*, which is thus emitted, is greatly dependent upon the nature of the heated surface; it is smallest from polished metallic surfaces, and greatest from rough and unmetallic surfaces. The radiating power, for instance, of polished silver, heated up to 212°, being = 1, that of a surface of writing paper is about = P. Whether colour has or has not any effect upon this escape of heat from surfaces, is a doubtful question.

That this radiant heat is susceptible of *reflection*, may be shown by holding a piece of polished tin plate opposite a fire in such a position as admits the reflection of the flame to be seen in it, when an impression of heat is at the same time perceived upon the face; if the surface of the tin plate be roughened or covered with paper, scarcely any heat is then thrown off, but the plate itself becomes hot in consequence of the *absorption* of the rays. This terrestrial radiant heat, especially when it emanates from surfaces which are not luminous, as from a flask of hot water, for instance, is to a great extent arrested in its progress by a plate of transparent glass, in which respect it appears to be unlike *solar* heat, which passes freely through all transparent media; but there are some substances which do not thus impede its progress; among them, a transparent plate of rock-salt is most remarkable, the rays proceeding through it with little interruption; such substances, therefore, have been termed *thermophanous* bodies. (See Melloni, *Annales de Chim. et Phys.* vol. liii.)

RA'DIARIES, *Radiaria*, or *Radiata*. (Lat. radius.) The name given by Cuvier to the lowest organized of the primary divisions of the animal kingdom; because certain of the animals therein included have a radiated form of a part or the whole of their body. *See* ACRITA, NEMATONEURA, ZOOPHYTA.

RADIATING POINT. In Optics, any point from which rays of light proceed.

RADIA'TION. (Lat. radius, *a ray*.) In Physics and Meteorology, the emission of rays of light or heat from a luminous or heated body.

The theory of the radiation and conduction of heat, which long remained one of the most obscure parts of physical inquiry, has been reduced by the successive labours of Prevost, Leslie, Fourier, Biot, Laplace, Poisson, Melloni, Forbes, and others to a purely mathematical form, and thereby placed in the same rank with physical optics, with which, indeed, it has many principles in common.

The general laws of the radiation of heat, which have been established by experiment, are the following: — 1. Like all other emanations, its intensity, in a vacuum, varies in the ratio of the inverse square of the distance from the radiating point. In air and the gases, the decrease is a little faster in consequence of a partial absorption. 2. The amount of radiation, or the rate at which a body parts with its heat, is proportional to the excess of the temperature of the body above that of the medium in which it is placed. This principle was assumed by Newton; and it follows from it that if the times of cooling be taken in an arithmetical progression, the heat will decrease in a geometrical progression. The principle, however, is found by experiment to hold good only within a certain range of temperature, not exceeding 50° of Fahrenheit. At the higher temperatures Dulong and Petit found the rate of cooling to be more rapid than in the ratio stated. 3. All bodies placed in an enclosed space assume in time the temperature of the enclosure. 4. Heat is emitted from every point of the surface of a hot body in all directions, and the intensity of the heating ray is as the sine of the angle which it makes with the surface. This result, which is by no means obvious, was discovered by Leslie; and its physical cause is, that radiation takes place not from the surface alone, but from particles situated within a certain minute but sensible depth, which is different for different surfaces. 5. The intensity of radiation varies with the nature of the radiating body, and the state of its surface with regard to polish, colour, source of heat, &c. It is greatest for rough and dark surfaces, and least for bright surfaces of polished metal.

The velocity with which radiated heat is propagated through space is entirely unknown. It is certain, however, that it is very great, and probably not inferior to that of light.

The doctrine of the radiation of heat was first stated in a precise and satisfactory manner by Prevost of Geneva, about 1790. Its leading principle being that all bodies are perpetually exchanging their heat with one another, it is sometimes called the *theory of exchanges*. As this emission of heat cannot be attributed to the body which receives it, but for the same radiating body and the same state of surface depends only on the temperature of the body, we are led to suppose that radiation takes place with greater or less intensity at all temperatures; that it is reciprocal between distant bodies; and that it subsists when the temperatures are equal, though in this case no alteration of temperature takes place. By a close attention to the phenomena, we are also led to infer that the faculty of the emission (and also of the absorption) of heat belongs to *all* the molecules of a body; and consequently that radiation takes place not only at the surfaces, but also in the interior of solids and liquids, in the same manner as it takes place in air, or differing only in consequence of its more rapid absorption. Fourier and Laplace were thus led to view the constituent molecules of all bodies as so many foci of radiating heat. This heat is radiated by every molecule in every direction, and is propagated through the pores or void spaces of ponderable matter, until it is entirely absorbed by the molecules which it encounters. In solids and liquids the absorption takes place at very small distances; in air and the gases at very great distances. The mathematical theory of heat is founded on this hypothesis of molecular radiation.

Solar and Terrestrial Radiation.—The measure of heat received from the sun, and of that which is constantly escaping from the earth into the regions of space, are among the most important elements of meteorology. If the earth were not surrounded with the atmosphere, the quantity of solar light received at any time on a given portion of its surface would be proportional to the inclination of the ray to the surface, or to the cosine of the sun's zenith distance; but owing to the modifying effects of the atmosphere, it would appear from the results of experiments that so far from this law holding good, the force of the sun's direct radiation rather increases with the latitude. Professor Daniell (*Meteorological Essays*, p. 228.) suggests that as the cooling power of the air has been proved to be in proportion to its elasticity, it is reasonable to suppose that the difficulty with which heat passes through the atmospere is in the same ratio. The proportion of solar heat absorbed in traversingt he atmosphere vertically has been estimated by Leslie and Pouillet at 25 parts in 100; by Kämptz at 32; and by Prof. Forbes at 29.

The force of solar radiation is measured by the excess of the temperature which a body assumes when exposed to the direct action of the sun's rays above that which it would have in the shade. This excess may be roughly measured by two common thermometers, one placed in the shade, and the other exposed to the sun and having its bulb covered to prevent reflexion. The most accurate measurement is, however, given by the *actinometer*, an instrument invented by Sir J. Herschel, in 1824, for the dynamical measure of solar radiation. A description of this valuable instrument, and full directions for the method of using it, are given in the *Report of the President and Council of the Royal Society on the Objects of Scientific Inquiry in Physics and Meteorology*, 1840.

From certain experiments made by Pouillet at Paris, he inferred that the whole amount of solar heat annually radiated to the earth is equal to that which would suffice to melt a stratum of ice about 14 mètres or 46 feet thick encrusting the whole earth (*Elémens de Physique et de Météorologie*); but in a subsequent memoir (*Sur la Chaleur Solaire*) he estimated the same quantity at 31 mètres, or 102 feet.

The measure of terrestrial radiation is of equal importance with that of solar radiation, but no perfect instrument has yet been contrived for its determination. The best means consist in the daily register of the minimum temperature shown by a register thermometer, the bulb of which is placed in the focus of a parabolic metallic mirror pointed towards the clear aspect of the sky, and defended from currents. It may be supposed that the same atmospheric causes which obstruct the passage of radiant heat from the sun oppose also its transmission from the earth into space.

From the theory of terrestrial radiation, a curious deduction was made by Fourier, with regard to the temperature of the region of space through which the earth moves in its orbital revolution. On computing the temperature which it is necessary to suppose the planetary spaces to possess in order that the thermometrical state of the earth's surface may be such as is actually observed,

he found that the existing phenomena correspond to those which would result from the supposition that the regions of space have a temperature of about —58° Fahrenheit. Svanberg arrived at the same conclusion by a different process, but others have given very different estimates. Thus Poisson makes it —13° cent. or +8½° Fahr., and Pouillet supposes it to be below —115° cent. or —175° Fahr. (See *Leslie's Experimental Inquiry into the Nature and Propagation of Heat*, 1804; Prevost, *Essai sur la Calorique Rayonnante*, 1809; Fourier, *Théorie Analytique de la Chaleur*, 1822; Laplace, *Mécanique Céléste*, tome v.; Poisson, *Théorie Mathematique de la Chaleur*, 1835; *Kelland's Theory of Heat*, 1837; *Reports to the British Association* for 1832, 1835, and 1840.)

RA'DICAL (Lat. radix, *a root*), in Chemistry, is a term occasionally used as synonymous with *base:* thus sulphur and phosphorus are the *radicals* of the sulphuric and phosphoric acids. The term *compound radical* is applied to certain organic combinations; in this case compounds of hydrogen, carbon, or nitrogen constitute the principal radicals.

RA'DICAL BASS. In Music, the same as *fundamental bass*, which see.

RA'DICAL REFORMERS. In Politics, that political party in England which desires to have the abuses which, from lapse of time or any other cause, may have crept into the government, completely *rooted out* (as the origin of the term implies); all our institutions remodelled; and, in short, a larger portion of the democratic spirit infused into the constitution.

RA'DICAL SIGN. In Algebra, the symbol $\surd$, denoting the extraction of a root. It is a modification of the letter *r*, the initial letter of *radix* or root. To distinguish the particular root which is to be extracted, a number is prefixed to the symbol; thus, $\sqrt[2]{}$, $\sqrt[3]{}$, $\sqrt[4]{}$, &c. denote respectively the square root, cube root, fourth root, &c.; but as the square root or second root was the first considered, the number is usually omitted, and merely the symbol $\surd$ written. Fractional exponents are frequently used instead of the radical sign. A *radical quantity* is a quantity to which the radical sign is prefixed.

RA'DICLE. In Botany, that portion of an embryo which eventually becomes the descending axis or root. It is the lowest of the two opposite cones of which an embryo plant consists.

RA'DIOLITES. A genus of fossil shells; the inferior valve of which is in the shape of a reversed cone, the superior valve convex.

RA'DIUS. (Lat. *a ray*.) In Geometry and Trigonometry, the semidiameter of a circle, or a straight line drawn from the centre to the circumference. In the trigonometrical tables the sines, cosines, tangents, &c. of circular arcs are expressed in parts of the radius, which is usually assumed equal to 1. The radius is equal to the side of the inscribed hexagon; or it is equal to an arc of 57·29578°, or 57° 17′ 44·81″, the semicircumferences, or 180°, in parts of the radius 1 being 3·1415927.

RADIUS. In Osteology, a bone of the forearm; so called from its supposed resemblance to the spoke of a wheel. Its upper end, which is the smallest, is formed into a round hollowed head, and is articulated with the small head at the side of the pulley of the humerus, whilst the rounded border of it next the ulna is articulated with the lesser sigmoid cavity of that bone; its lower extremity is articulated with the bones of the wrist.

RADIUS OF CURVATURE. In the higher Geometry, the radius of curvature at any point of a curve line is the radius of the circle which *osculates* the curve at the given point (*see* OSCULATION), or has the same curvature as the curve at that point. The curvature of a circle being uniform, and inversely as the radius, the radius of the osculating circle enables us to judge of the curvature of any curve line at its different points. The general expression for the radius of curvature, *r*, of any plane curve defined by the equation $y = f(x)$, is

$$r = \frac{(dx^2 + dy^2)^{\frac{3}{2}}}{dx\,d^2y}.$$

(*See* EVOLUTE.) From this expression the value of r is readily found when the equation of the curve is given; it is a property of lines of the second order, that the radius of curvature is equal to the cube of the normal divided by the square of the semiparameter.

The expression for the radius of curvature of a surface represented by the equation $z = f(xy)$, at any point whose co-ordinates are x, y, z, is as follows: — Make

$$\frac{dy}{dx} = m,\ \frac{dz}{dx} = p,\ \frac{dz}{dy} = q,$$

$$\frac{d^2z}{dx^2} = r,\ \frac{d^2z}{dx\,dy} = s,\ \frac{d^2z}{dy^2} = t,$$

and let R denote the radius of curvature of a normal section of the surface; then

$$R = \frac{\sqrt{1 + p^2 + q^2}\left((1 + p^2) + 2pqm + (1 + q^2)m^2\right)}{r + 2sm + tm^2}.$$

RA'DIUS VE'CTOR. In Astronomy, is the straight line drawn from the centre of force to the point of the orbit, where the body is supposed to be. A body projected in space, and subjected to the action of a centripetal force, as gravity, which varies in the inverse ratio of the distance, describes a conic section which has one of its foci at the centre of force. In the parabola, let p denote the parameter; and in the ellipse and hyperbola, let a denote the semitransverse axis, and e the eccentricity; also let r denote the radius vector, and v the angle which it makes with the transverse axis; then the expression for the radius vector in the parabola, the ellipse, and the hyperbola respectively, is

$$r = \frac{\frac{1}{2}p}{1 + \cos. v},\ r = \frac{a^2 - e^2}{a + e\cos. v},\ r = \frac{e^2 - a^2}{a + e\cos. v}.$$

These expressions are called the *polar equations* of the three curves.

RA'DIX, or ROOT. *See* ROOT.

RAFT. A species of float formed of various logs or planks, fastened together side by side, so as to be conveyed from one point to another. This means of conveying timber to the sea-coast is advantageously practised in many places. The following notice of the plan adopted on the Rhine, of bringing the vast quantities of trees felled near its source down to the navigable stations on its banks, may be interesting to the reader: —

A little below Andernach the little village of Namedy appears on the left bank, under a wooded mountain. The Rhine here forms a bay, where the pilots are accustomed to unite together the small rafts of timber floated down the tributary rivers into the Rhine, and to construct enormous floats, which are navigated to Dordrecht, and sold. These machines have the appearance of a floating village, composed of 12 or 15 little wooden huts, on a platform of oak and deal timber. They are frequently 800 or 900 feet in length, and 60 or 70 in breadth. The rowers and workmen sometimes amount to 700 or 800, superintended by pilots, and a proprietor, whose habitation is superior in size and elegance to the rest. The raft is composed of several layers of trees, placed one on the other, and bound together: a large raft draws not less than 6 or 7 feet of water. Several smaller ones are attached to it, by way of protection, besides a string of boats loaded with anchors and cables, and used for the purpose of sounding the river and going on shore. The domestic economy of an East Indiaman or an English man of war is hardly more complete. Poultry, pigs, and other animals are to be found on board; and several butchers are attached to the suite. A well-supplied boiler is at work night and day in the kitchen; the dinner hour is announced by a basket stuck on a pole, at which signal the pilot gives the word of command, and the workmen run from all quarters to receive their messes. The consumption of provisions in the voyage to Holland is almost incredible; sometimes amounting to 40,000 or 50,000 pounds of bread; 18,000 or 20,000 of fresh, besides a quantity of salted meat; and butter, vegetables, &c., in proportion. The expenses are so great, that a capital of three or four hundred florins is considered necessary to undertake a raft. Their navigation is a matter of considerable skill, owing to the abrupt windings, the rocks, and shallows of the river; and some years ago the secret was thought to be monopolised by a boatman of Rüdesheim and his sons. (*Autumn on the Rhine.*)

RA'FTER. (Sax. ræꝼτeɲ.) In Architecture, an inclined piece of timber in the side of a roof; in the provinces called a *spar*. It is of various sorts, as will be seen under the art. ROOF, which see.

RAG-STONE. A dark grey silicious sandstone.

RAIL. In Architecture, the horizontal part in any piece of framing or panelling. Thus in a door the horizontal pieces between which the panels lie are called *rails*, whilst the vertical pieces between which the panels are inserted are called *styles*.

RAIL, or WATER-RAIL. (*Rallus aquaticus* of Lin.) A native species of a genus of Macrodactyle or long-toed waders, destitute of alar spines or a frontal shield.

RAI'LING. A fence or barrier made of posts and rails. The most ordinary fence of this description in the country is formed of wooden posts let into the soil, so as to stand upright, to which are nailed or morticed horizontal wooden rails, one above another, at such a distance as to prevent domestic animals from penetrating through them. In some cases one horizontal rail is fixed to the posts near the ground, and another near the top of the post, and the interval between them is rendered impervious to cattle by upright rails nailed to the top and bottom horizontal rail. Iron railings are generally formed in this manner.

RAILROADS, or RAILWAYS. Roads constructed of tracks of iron called *rails*, on which the wheels of carriages roll, and to which they are confined by ledges or *flanges* raised either on the rail or on the tires of the wheels.

Theory of Railways. — The object to be attained by the

construction of roads of every kind is to effect the transport of loads by the least possible expenditure of tractive force; and one road is better or worse than another, *ceteris paribus*, according as the same moving power is capable of drawing upon it a greater or less amount of load. Since the moving power, whatever it may be, is expended in overcoming the resistance which the carriages on which the load is borne offers, this object can only be attainable by the adoption of such expedients as will permanently diminish the amount of that resistance. The causes of resistance to the motion of a carriage along the road are the following: —

1. *Roughness or Unevenness of the Road Surface.* — All asperities formed by stones or other hard substances projecting above the general surface of the road produce a resistance to the moving power, since, when the wheels encounter them and pass over them, the weight of the load, resting as it does upon the wheels, must be raised through a height corresponding with such projections; and, when such projections are frequent or continued, this expenditure of the moving power is also continued, and the same species of resistance is produced as if the moving power had *continually* to raise an equivalent weight. In like manner, if cavities or *ruts* occur on the road surface, the wheels sink into them, and the moving power is constantly expended in raising the load out of these cavities. All roughness or unevenness of surface consisting of nothing more than a multitude of such projections and cavities more or less minute in magnitude, the same causes operate by such means in absorbing the moving power.

2. *Softness of the Road.* — However free the road surface may be from asperities or cavities, if its substructure be of such a nature that it will yield to the pressure of the wheels, a resistance will be produced to the moving power, the amount of which will be more or less, according to the degree in which this softness or yielding quality exists. The wheels sinking into a cavity produced in the soft surface of the road by their pressure, the moving power is affected in nearly the same manner as if it had to draw the load out of the cavity which it makes for itself, and a corresponding amount of resistance is the consequence.

3. *Acclivity of the Road Surface.* — When the surface of the road is not perfectly horizontal, but forms an inclined plane up which the load is to be drawn, a resistance will be produced by the gravity or weight of the load, which will be proportional to the steepness of the acclivity: thus, if the road surface rise, in the direction of the motion, one perpendicular foot in 50 feet of distance, then as much moving power will be absorbed in going over every 50 feet of distance as would lift the entire load through one foot of perpendicular height.

This cause of resistance differs from the former *causes*. In both the former the resistance to the moving power would be equally produced in whichever direction the load is drawn; but the effect of an acclivity is to increase the resistance only in the ascending direction. In the descending direction, on the other hand, it will have the effect of assisting the moving power, by causing the gravity of the load to co-operate with that power in overcoming the other resistance. In all roads, therefore, on which the traffic is equal in both directions, the advantage derived from descending acclivities is to be placed against the power expended in ascending them. The principles on which the question of the best possible arrangement of the acclivities on roads of different kinds depends are of great importance, not only with reference to the working of roads, but also in laying them out, or originally constructing them; and there is none about which there has been, and still is, a greater difference of opinion among engineers and men of practical science.

Such, therefore, being the sources of resistance, the qualities which must be imparted to a road, to diminish as much as possible the resistance to the moving power, must be the following: —

1st, Smoothness and evenness of the road surface.

2d, Hardness and durability of the road structure.

3d, Such an arrangement of the acclivities that the effect of the gravity of the load shall produce on the whole the least amount of resistance, or that it shall contribute the greatest amount of advantage to the moving power.

In ordinary roads formed of gravel, broken stone, or pavement, the entire surface is constructed in an uniform manner, so that every part of it is equally adapted to the motion of the wheels; and, as the tractive power commonly used is the strength of horses, the structure of the road must also be more or less made with a view to their qualities. Thus it might happen that the great degree of smoothness and hardness which would contribute most effectually to diminish the resistance of the carriages would be incompatible with the continued health and soundness of the horses working on it. The paved streets of a town, by reason of their hardness, produce less resistance to the motion of carriages than the softer gravel roads of the country, but they are incomparably more injurious to the horses which work upon them.

This difficulty is met by appropriating certain parts only of the road to the action of the wheels, and imparting to these, in the highest practicable degree, the qualities necessary to diminish the resistance, and to give the greatest durability to the road; and, on the other hand, to adapt that part of the road appropriated to the horses to the peculiar action of their feet, and to the circumstances of the structure and health of the animal.

This has been accomplished by constructing upon the roadway parallel tracks, with a width corresponding to the distance between the wheels, and between these tracks forming a path suitable to the horses.

Another advantage attending such an arrangement is, that the extent of the road surface adapted to the action of the wheels is extremely limited, and a greater amount of expense can be incurred in giving it the necessary smoothness, hardness, strength and durability, than could be at all practicable if these qualities were to be imparted, as in common roads, to the whole extent of the road surface.

Such are the general principles which have led, through a succession of stages of progressive improvement, to that most perfect of all the instruments of transport which human invention has yet devised, — the modern railway. Such a road consists of two parallel tracks of iron firmly maintained in their places, the upper surfaces of which are rendered in a very high degree smooth and level, a strength being given to them which renders them capable of sustaining enormous loads without being deranged in their structure or position. The carriages are maintained upon such tracks or ledges by means of a projecting flange which is constructed upon the inside of the tires of the carriage wheels, and which, by pressing on the inside of either rail, prevents the carriages from escaping from the rails. The general method of constructing such roads will be rendered most easily and agreeably intelligible by a brief view of their history from their first invention to their present state.

History of Railways. — About the middle of the 17th century, the transport of coals from the pits to the harbour was effected in the coal districts of Northumberland and Durham by laying down parallel tracks of timber with a horse path between them, the wheels being confined upon the beams or rails of timber by ledges or flanges projecting from the inside of the tire of the wheels. These timber rails were constructed in pieces of about 6 feet long with a section of about 4 inches square; they were supported on pieces of timber called *sleepers* laid at right angles to them transversely on the road. These sleepers were laid at about two feet apart, so that each pair of parallel rails was supported by three sleepers; besides giving support to the rails, these sleepers also had the effect of maintaining the rails in gauge, or in keeping them at a fixed distance asunder. The rails were fastened to the sleepers by pins driven quite through the rails, and half way through the sleepers, to preserve the uniformity of the upper surface of the rail; these wooden pins were planed off at the top.

The necessity of giving room for the flanges of the wheels, running as they did below the surface of the rail, and the small depth between the surface of the rail and the sleeper, rendered it impossible to protect the sleepers effectually from the action of the horses' feet by any covering of gravel or other material. The sleepers were consequently subject to be worn and destroyed. The rails also, being worn by the action of the wheels still more rapidly than the sleepers, required to be frequently replaced; and, each new rail being pinned down to the same sleeper, the ends of the sleepers were gradually perforated by so many holes that the sleepers were weakened and required to be soon replaced. These defects were remedied by the adoption of the double timber railway, which consisted in laying upon the surface of the timber rails, above described, additional rails of timber of equal scantling, attached to the lower rails by wooden pins, passing quite through the upper and half through the lower rails, in the same manner as the lower rails themselves were attached to the transverse sleepers. This change was attended with many advantages. Besides the increased strength given to the rails by the double timbers, the depth of the sleepers below the upper surface of the superior rail allowed the sleepers to be protected from the action of the horses' feet by covering them with broken stones, gravel, or other road materials. The structure of rails and sleepers also being stronger and more weighty, and held down by the road material with which the sleepers were covered, allowed a packing or ballasting to be driven under the rails, so as to give greater stability and firmness to the road. Another advantage obtained by this arrangement was, that when the superior rails were worn by the action of the wheels, they could be replaced by new ones without disturbing the inferior rails; and as the places of the joints, and those at which they were attached by pins to the inferior rails, could be varied at pleasure, the pin-holes made in the inferior rails would not come in the same place, or near each other, so as injuriously to weaken the latter.

The next improvement consisted in the addition of a plate or bar of iron, about two inches broad and half an inch thick, laid along the upper surface of the superior rail, and attached to it by nails or iron pins countersunk in it. The wheels of the carriages ran upon this iron rail, which formed a more durable surface than that of the wood. In the United States of America, railways of this construction are still in very general use. They are recommended in that country by the abundance and cheapness of timber, and the comparative high cost of iron. Such a road is tolerably efficient where the traffic is light, and can therefore be resorted to in localities and circumstances in which an adequate return could not be obtained for the capital necessary for the construction of the more perfect modern railway. In the construction of these timber railways in America many other improvements have been introduced, more especially in the substructure of the road. In laying out the roadway for the reception of the rails, two parallel trenches are cut along the line of way corresponding to the distance between the rails, and transverse trenches at right angles to these are cut to receive the sleepers: these trenches are respectively bottomed with a ballasting of broken stone, on which the rails and cross sleepers rest. This basis answers the double purpose of a firm and durable support for the road and an effectual means of drainage. The scantling of the timbers used for the rails is usually six inches in width by ten inches in depth: they are attached to the sleepers, so as to be at once kept from springing from them and from altering their gauge, by the following means:—A notch is cut in the sleeper corresponding to the size and form of the rail; and the rail, at the place where it is let into the sleeper, is formed with a vertical surface on the outside, and a levelled surface on the inside, increasing in width downwards. When let into the notch of the sleeper, the levelled part of the rail is forced into the corresponding cavity of the notch by a wedge driven between the outside edge of the rail and the outer surface of the notch.

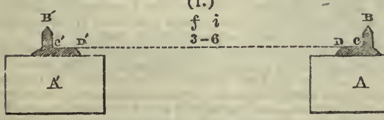
An expedient based upon the general principle of railways has been adopted, but from what date we are not informed, in the streets of some of the Italian cities, and more particularly in those of Milan. Parallel tracks of hewn stone are laid down to receive the wheels of carriages, and such a width is given to them as to be accommodated to any variations which are usual in the structure of carriages. This width is also such that the wheels are not liable to run off these flagged paths by any irregularity in the course which the horse takes in drawing the carriage.

Great facility of draught is obtained by this expedient, which has been of late years adopted with some improvement in England. A flagged trackway of this kind was constructed some years ago, and is still in operation, extending from the West India Docks, along the Commercial Road, towards the City of London, and a similar expedient has been more recently proposed to facilitate the application of steam power on common roads. Stone track ways of this kind have been accordingly laid down on some parts of the high road between London and Birmingham. This expedient has the advantage in one respect over railways, inasmuch as the carriages are not confined by flanges or any other expedient to the stone paths on which the wheels move, and consequently the same carriages which run upon them may also move on other parts of the road. Thus, one carriage may pass another, while both use the same line of stone rails, which cannot be effected when carriages are confined to the rails.

In the progress of improvement, the timber railway above described was succeeded by the last iron plate railway, or tramway, which was for a long period used exclusively in the coal districts, and in public works generally, and is still to a considerable extent adopted, especially in the railways which are carried through the workings of mines, and on which the product of the mine is conducted in waggons, being pushed by men or drawn by horses to the foot of the shaft.

The Plate Railway, or Tramway.—About the year 1770 tramways of cast iron came into use in the collieries in the north of England. These railways consisted of two rails of cast iron laid parallel to each other at a distance from three to three and a half feet asunder. They were usually supported either on timber or stone bearings. A cross vertical section of these as first used is represented at fig. 1.; where A A′ represents the timber supports,

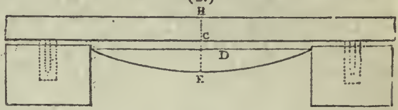
(1.)



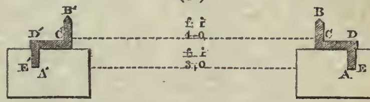
B C D, B′ C′ D′ represent the sections of the rails, C D, C′ D′ represent the horizontal plates attached by nails or pins to the sleeper. On this plate the wheel of the waggon rolled. The ledges B C, B′ C′ rose perpendicularly two and a half inches on the outside edge C′ of each plate C′ D′. These ledges, by pressing on the outside of the wheels, prevented the waggon from escaping from the road. They were subsequently raised on the *inside* of the horizontal plate, so as to act on the *inside* of the wheels.

In order to give such rails strength in the vertical direction, to supersede the necessity of a continued support beneath them, they were afterwards cast with a ledge beneath them, projecting downwards from the outside edge of the horizontal plate. A side view of such a rail is represented in fig. 2., and a cross section of the rails in fig. 3.

(2.)



(3.)



The upright ledges B C, B′C′ (fig. 3.) rising from the horizontal plates C D, C′D′, and coming within each wheel, kept the wheels on the rails; and the ledge D E, D′E′, projecting downwards, and increasing in depth towards the middle of the distance between the supports, as represented in fig. 2., gave the necessary strength to the rail. The outlines of this ledge formed each a curve, so that the strength at different points between the supports might be proportioned to the mechanical effect of the vertical pressure. The flanges B C, B′C′ are the same height throughout the whole length of the rail.

These tramways were for a long period constructed exclusively of cast iron; but, when improved methods of rolling malleable iron were contrived, they were formed by rolling; and for nearly twenty years back they have been constructed exclusively of wrought iron.

Edge Railway.—Within twenty years after the first introduction of tramways of iron, the form of rail called the *edge rail* was brought into use. This rail is constructed in the form of a bar of iron, whose width is considerably less than its depth, placed, as the name implies, with its narrow edge presented upwards. Owing to its depth being much greater than its width, its power, in proportion to its weight to resist vertical pressure, is very considerable. The wheels were retained on rails of this description by flanges projecting from the inside of their tires. These flanges, at the point where the wheels rest on the rails, descend below the rails; and the wheel cannot pass off the rail towards the outside, unless the flange rolls over the rail.

For a long period after their first adoption, edge railways were confined to the mining districts, and more particularly to the collieries, where they were used for the transport of the products of the mines to the places of shipment; but this species of road acquired vastly increased importance when passengers and goods came to be transported on it by locomotive engines, which took place between Liverpool and Manchester in the year 1830. Since that time, the construction of railways adapted for general traffic, at a speed which until within the last ten years would have been thought impossible, has been carried to a great extent in England, and in the United States. Lines of railway with the same object have likewise been projected, and some of limited extent constructed in different parts of Europe. The general flatness of Belgium offering the greatest facilities for the construction of this kind of road, lines of railway have been brought into operation between the chief towns of that country, and it is intended to continue these lines to Aix-la-Chapelle, from which a line was recently opened to Cologne. *The Times* of Dec. 16. 1841, gives a list of the various railroads projected, in progress, and completed, in Germany, down to that date.

In France, the only railways worked by steam power, adapted for passengers, which have yet been brought into operation, are the short lines connecting Versailles and St. Germain with Paris. Several others of greater extent are, however, in progress; among which may be mentioned, more particularly, the Paris and Havre line, by which, combined with the London and Southampton railway, the French metropolis will be accessible by a journey of twenty-four hours or less from London.

Within the limits of the present article, it would not be possible to trace, in the order of time, the succession of improvements by which the present methods of laying out and constructing railways for the swift transport of passengers by steam power have been attained. When

the Liverpool and Manchester line was first brought into operation, little, comparatively, was understood of the capabilities of such means of intercommunication; and that line may be regarded as an experimental railway, the results of which have supplied the data on which others have since been constructed and worked. The form, strength, and weight of the rails, — the mode of fixing them on the road, — the weight, power, and proportions of the engines, — the form, strength, and weight of the carriages and waggons, — the magnitudes of the trains, and the speed of transport, have all been subject to change from year to year, and almost from month to month, since the opening of that line in 1830 to the present time. We shall not therefore attempt to trace these improvements; but shall briefly explain the formation and construction of railways, according to the methods and principles at present generally received.

Of the Formation and Construction of Railways. — Whatever be the moving power to be used for the transport of loads upon a railway, its force must be proportioned to the average resistance of such loads, and it must be capable of varying its energy to the same extent as that resistance is subject to variation. The great perfection which has been attained in the construction of the rails, and in the methods of fixing them in their position upon the road, is such, that the resistance offered to the tractive power by loads moved on a straight and level railway may be regarded as practically uniform, so that the moving power by which a load is transported at a given speed on a straight and level line of railway is subject to a resistance as unvaried and as uniform as any to which moving powers are usually submitted in any of the processes of art; but as the amount of resistance to the tractive powers upon a straight and level railway is diminished by the perfection thus attained in the construction of the road, so, in the same degree, is any resistance produced by a departure from a perfect level more sensibly felt. Thus, if the resistance to the moving power on a straight and level railway, by a load moved at a given speed, be equal to the 250th part of the load, an acclivity which would rise at the rate of one foot in 250, or nearly at the rate of 20 perpendicular feet in a mile, would produce a resistance to the moving power, by reason of the ascent alone, equal to a 250th part of the load, and therefore equal to the resistance which the moving power would sustain on a level line. It follows, therefore, that, under such circumstances, in drawing a load up such an acclivity, the moving power would have to overcome twice the resistance opposed to it on a level; for the same causes which produce on a level a resistance amounting to the 250th part of the load equally produce this resistance in ascending the acclivity, in addition to which there would be an equal amount of resistance due to the ascent. If, therefore, under such circumstances, the moving power were required to draw the load up the acclivity at the same speed as that at which it drew it on the level, the machine exerting that power must be endowed with properties in virtue of which it is capable of varying its energy, without injury to its structure, in the proportion of two to one.

Whether such limits of variation in the resistance or in the moving power as are here referred to for the sake of illustration be those which are requisite in practice or not, it is apparent that *some* practical limits must exist to the variation of the resistance; and that, whatever these limits may be, corresponding limits must be imposed on the acclivities or *gradients*, as they have been called, which are admissible on the railway on which such moving power is to be applied. If the moving power be incapable of increasing its energy in a greater proportion than two to one; then the steepest gradients must not create more than twice the resistance on the level parts of the line; and, if the resistance on the level parts of the line be equal to the 250th part of the load, the steepest gradients ought not exceed one in 250. This, however, proceeds on the supposition that the *same speed* is required to be maintained in ascending the acclivities as on the level.

When a carriage of any kind changes the direction of its motion, it does not accomplish this by suddenly passing from motion in the one direction to motion in the other. Many mechanical effects, which will be sufficiently obvious, forbid this. The change of direction is, on the other hand, effected gradually, by causing the carriage to move in a curve. Now, in such a motion, it is evident that the wheels which traverse the outer part of the curve will in the same time move over a greater space than those which traverse the inner part; in fact, the inner and outer wheels move over arches of circles which have the same centre, the outer arch being longer than the inner. If the wheels, therefore, be (as they always are) of the same magnitude, the outer wheel must revolve oftener on its axle in passing over the curve than the inner; but, besides this, the position assumed by the wheels in passing round a curve is different from that which they have when moving in a straight line. If a four-wheel carriage move along a straight road, its axles will be at right angles to the direction of its motion, and therefore parallel to each other; but if it move in a curve, which it does in turning a corner, then its axles are no longer parallel, but each of them is directed to the centre of the curve which the carriage describes. The mechanism by which this effect is provided for by four-wheel carriages, used on common roads, is the perch or pivot on which the axle of the fore wheels is made to turn. By this pivot the fore axle may be placed at any required angle with the axle of the hind wheels. As the wheels of all such carriages revolve independently of each other, each upon its own axle, the wheels on the same axle may revolve at different speeds. These two provisions, therefore, are brought into play when a common carriage changes its direction. The outer wheels, in turning round the curve, move faster than the inner, and the axles throw themselves out of parallelism, and take the directions of the radii of the curve.

The peculiar structure of railway carriages excludes the possibility of either of these provisions for turning round a curve. To maintain in security the carriages on the rails, it has been found necessary to fix the axles truly square with the carriages, and therefore to exclude the pivot or perch by which a common carriage is turned. It has likewise been found necessary to key the wheels firmly upon the axle, so that the wheels and axle shall turn together, instead of the axle being fixed, as in a common carriage, and the wheels turning upon it. The mechanism of a railway carriage is therefore essentially adapted to rectilinear motion, and it contains no expedient by which it can move round a curve. When such a carriage, therefore, first encounters a curve, its tendency is to proceed in the continuation of the straight line in which it has previously moved, and which forms a tangent to the curve. If this tendency were allowed to take effect, the outer wheel would run off the rail on the outside of the curve, and the inner wheel would come off the rail in the space between the rails. This is prevented by the flange which projects from the tire of the outer wheel, and which, at the point where that wheel rests upon the rail, descends below the rail. When the wheel makes an effort, in virtue of the tendency to rectilinear motion, to pass off the rail, the flange comes in contact with the inside of the rail, and, by pressing upon it, throws the carriage inwards; and this taking place with the fore wheels, the direction of the body of the carriage is shifted, and it is thrown more nearly square with the rails. This action of the flange is continued while the carriage is passing round the curve, and it is to it alone that the change of direction of the carriage is due.

The tires of the wheels of railway carriages have usually a conical form given to them, becoming gradually smaller from the flange outwards; and, when a carriage rests straight upon the rails, the distance between the flanges of the wheels being less than the distance between the rails, a small space is left between the flanges and the rails, to allow some play to the flanges without letting them strike the rails. When the carriage comes to a curve, the flange of the outer wheel comes into contact with the outer rail, and the whole play of the flanges is given to the space between the flange of the inner wheel and the inner rail. In consequence of the conical form of the tires of the wheels, the outer wheels, in this case, rest upon a thicker part of the cone than the inner, and the actual diameter on which they revolve is consequently greater than that on which the inner wheels revolve. This effect has been generally regarded as an expedient sufficient to enable railway carriages to run round curves of a certain limited radius; but that this is an error may be easily shown, — if, to a four-wheel carriage, wheels of unequal diameter be attached, smaller wheels being put on the one side than on the other, and if such wheels were attached to their axles, so that the axles revolve with them, and if at the same time the axles be fixed square with the carriage, *such a carriage will be found to be incapable of moving in a curve, notwithstanding the inequality of its wheels.*

The pressure of the flange on the rail being, therefore, the only means of turning a railway carriage round a curve, and such pressure being attended by friction, and therefore by increased resistance to the moving power, curves as well as acclivities are a cause of resistance, and this resistance will be great in proportion to the rapidity of the curve or the shortness of its radius. But, independently of this effect of curves, a more serious objection to those whose radius is under a certain limit of magnitude arises from the liability of the carriages to run off, by the flange encountering any obstacle or inequality which would cause it to pass over the rails.

The *section* of a railway is therefore limited by those circumstances which govern its acclivities, already explained, and which are equally related to the amount of the resistance on level rails, and to the practical limits of the variation of the moving power; and the *plan* is, on the other hand, limited by the necessity of effecting every change of direction of the line by curves whose radius shall have such a magnitude as to exclude all danger of

the carriages running off the line. In the laying out of a railway, therefore, limitations of its section and plan must be kept constantly in view.

Since the natural surface of a country is rarely adapted to the conditions which have been thus shown to be necessary to the formation of a railway, an artificial surface must generally be formed by raising some and lowering other parts of the country through which the railway is to pass. The expedients by which this is accomplished are attended with more or less difficulty and expense, and the skill of the engineer is eminently required in the selection of such a course for a proposed line of railway as will be attended with the least expensive construction, due regard being had to the permanent expense of working and maintaining it.

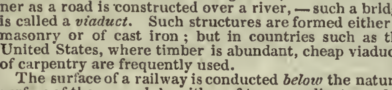
When a railway is proposed to be constructed between two points, which are called its *terminii*, the engineer makes himself generally acquainted with the country between these terminii, and selects that course for the line which, with least deviation from a straight line joining the proposed termini, will afford the greatest facilities for the formation of the artificial surface of the railway, limited as it must be in respect to its acclivities, and to the curves by which its various changes of direction are effected. This is first accomplished by an *eye survey* or general *reconnoissance* of the country. An instrumental survey is afterwards made along the direction which has been selected for the line, and a nearly accurate profile of the country from terminus to terminus, in the proposed direction, is obtained. This being accomplished and reduced to a drawing, as represented in fig. 4., a line

(4.)

A B C D E G H I K is drawn, regulated by the degrees of inclination which have been decided to be the best practical limits of the acclivities. This line will, as represented in the figure, in some places, as A B, C D, E F, G H, I K, pass above, and in others, B C, D E, F G, H I, below, the natural surface of the ground. It is therefore to be considered that, in the one case, the artificial surface of the line must be elevated above the natural surface; and that, in the other case, some expedient must be provided by which the artificial surface may pass at the requisite depth below the natural surface.

The surface of a railway is raised *above* the natural surface of the ground by either of two expedients; — 1st, by forming a mound of earth with sloping sides, having the railway on its summit, — this is called an *embankment* (fig. 5.); 2dly, by constructing a bridge by which

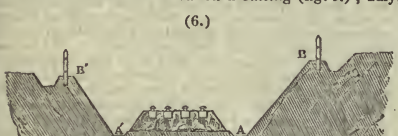
(5.)



the railway can be conducted, at the requisite elevation, above the natural surface of the ground, in the same manner as a road is constructed over a river, — such a bridge is called a *viaduct*. Such structures are formed either of masonry or of cast iron; but in countries such as the United States, where timber is abundant, cheap viaducts of carpentry are frequently used.

The surface of a railway is conducted *below* the natural surface of the ground by either of two expedients; — 1st, by forming an excavation, or artificial valley, with sloping sides, along the bottom of which the railway is constructed, — such an excavation is called a *cutting* (fig. 6.); 2dly,

(6.)



by undermining the ground and constructing a subterranean archway or vault of sufficient magnitude, the roof of which is usually lined with masonry, and along the bottom of which the railway is conducted, — such an archway is called a *tunnel*.

In laying out a railway, the disposition of its cuttings and embankments must be kept in view. In general, the material by which the embankments are formed is obtained from the cuttings; and, with a view to the saving of expense, the engineer so arranges his section that the quantity of stuff required for the formation of embankments shall be as nearly as possible equal to that supplied by the cuttings. If there be an excess of stuff from the cuttings, ground must be obtained in some position near the cuttings whereon it can be thrown. This is technically called *putting it to spoil*.

If, on the other hand, there be an excess of embankment, then the stuff necessary for the formation of such embankment must be obtained from some excavation made near the embankment expressly to supply the stuff for the embankment. This is called *side cutting*.

The distance along which the stuff obtained from a cutting is carried before it is laid down to form the embankment is called *the lead;* and the quantity of labour necessary to form an embankment out of an adjacent cutting is determined by the number of cubic yards of stuff necessary to form the embankment multiplied by the average *lead*, or the mean distance to which such stuff has to be carried.

Where a very low and long embankment occurs, it may happen that the *lead* is so long that the expense of forming the embankment from the nearest cutting would be greater than the expense of putting the cutting *to spoil*, and of forming the embankment from *side cutting*. These are questions which are determined in each individual case with reference to the price of land and labour.

When the elevation above the natural surface of the ground at which the railway must be carried is so great as to render an embankment impracticable, or attended with a disproportionate expense, a viaduct is resorted to; and, on the other hand, when the excavation necessary to give an open cutting would be productive of objectionable expense, then the railway is conducted under the ground through a tunnel.

The slopes A B, A′ B′, fig. 5, 6., forming the sides of embankments and cuttings, depend on the nature of the soil or strata through which the cuttings are made, and of which the embankments are formed. In general, every material has a certain angle at which it will rest, all more steep angles causing it to slip or fall: this angle is called, in mechanics, the *angle of repose*. In the strata through which railway cuttings are made, and from which embankments are usually formed, the slopes of the sides are rarely less than $1\frac{1}{2}$ foot horizontal to 1 foot vertical, and they vary between that and 2 feet horizontal to 1 foot vertical. When the material is gravel, sand, loose chalk, or gravelly clay, a slope of $1\frac{1}{2}$ to 1 is generally found sufficient; but with certain descriptions of clay, such as that called the London clay, a more gradual slope must be allowed. With such material, the slopes are constructed at $1\frac{3}{4}$ or 2 horizontal to 1 vertical; but in general it is better, even at increased expense of earthwork, to allow a sufficient slope in the commencement, and thereby avoid the continual expense attending *slips*, as the gradual decadence of the sides of cuttings and embankments is called.

The face of slopes, both of cuttings and embankments, should be covered with soil and sown with grass seeds, so as to produce a turf, which gives a further security against *slips*. They may be also, especially the slopes of embankments, planted with shrubs; care being taken, however, not to obstruct the ventilation of the road.

When the stratum through which a cutting is required to be made is rock or hard stratified chalk, it will stand with perpendicular sides; and, in such cases, cuttings of great depths may be made at a trifling sacrifice of land. The Olive Mount cutting on the Liverpool and Manchester railway is, at the deepest parts, above 100 perpendicular feet from the natural level of the surface to the level of the rails; and cuttings of still greater depth and much greater extent, through stratified chalk, are executed on the Brighton railway, of which the sides are perpendicular.

In most cases, however, where cuttings attain to these extraordinary depths, tunnels would be less expensive. It sometimes happens that the material of the cutting is required for an adjacent embankment; and, under such circumstances, if the sides of the cutting can be perpendicular, and the sacrifice of land small, it may be preferable to *tunnelling*. The materials from the Olive Mount cutting above mentioned were required for the formation of the broad green embankment adjacent to it.

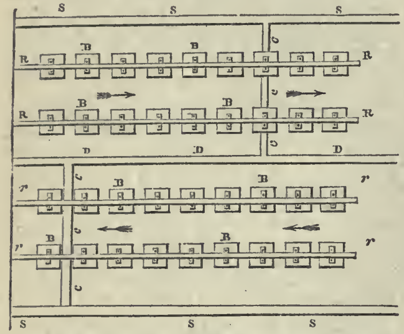
Drainage. — *The formation level*, as the artificial surface of the road intended to receive the rails and their supports is called, should be properly drained. This is effected by a centre drain, carried along the middle of the road, with cross drains at proper intervals communicating with side drains in the cuttings, and discharging the water down sloping drains descending the sides or embankments. The centre and cross drains are covered drains, formed either of brick or stone, or, more economically, of tiles made of a proper form for the purpose.

Road Structure. — The surface of the road being pre-

pared to receive the rails, the props or *chairs* which at fixed intervals form the support of the rails must next be laid down. These are sustained on supports of either of two kinds:—

1st, In cuttings, or on well-consolidated embankments, stone blocks are provided, roughly formed into a rectangular parallelopiped, the base of which is a square whose side is 2 feet, and the height of which is 1 foot. A bottoming of broken stone and gravel being spread to receive these, they are set upon it by raising them repeatedly by means of a lever, and letting them fall in the place where they are intended to rest, until they beat for themselves a solid and unyielding bed. It was the practice to lay these blocks so that their sides were parallel and perpendicular to the sides of the railway. In fig. 7.

(7.)

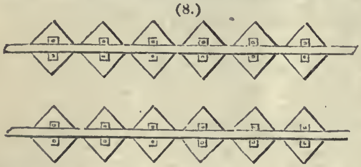


is represented the plan of a railway thus laid on blocks, showing its drainage, consisting, as is usual with railways having extensive traffic, of two lines. The line R R, R′ R′ is appropriated to carriages moving in one direction, and the line *r r*, *r′ r′* to carriages moving in the other direction. By thus causing carriages moving in the same direction to be confined to the same line, the collision of trains *meeting* is prevented. The centre drain running between the two lines of railway is represented at D D D. The cross drains are shown at C C C, communicating with the side drains S S S.

The blocks are represented at B B, supporting the rails, and laid with their sides parallel and perpendicular to the rails.

This arrangement has lately been superseded by the diagonal arrangement of blocks represented in fig. 8. It

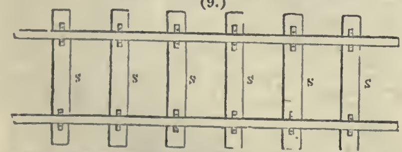
(8.)



is considered that this arrangement gives the block a better bearing on its bed; but the chief advantage attending it, as compared with the former position of the blocks, is that it renders the base of the block more accessible for repairing and adjustment, from time to time, when the road is in operation.

2dly, On embankments newly made, or other parts of the line where the foundation of the road is liable to yield under the operation of the traffic upon it, wooden sleepers, S S, fig. 9. extending across the road, are used instead of

(9.)



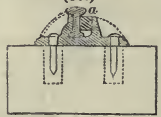
stone blocks to support the chains. These are usually formed of larch: the tree is split along the centre, so as to form two sleepers, one side of which is flat, and the other convex. They are usually from 8 to 9 feet long, and from 9 to 10 inches broad on the flat side; and from 4 to 5 inches deep, measured in the thickest part. They are laid across the road, with the flat side downwards. The chairs are fastened to them by pins on the convex side, in the same manner as they have been already described to be fastened to the blocks. Each pair of opposite chairs being thus connected, by being attached to the same sleeper, the rails are kept in gauge, notwithstanding the yielding of the foundation under the sleeper.

Until within a recent period, stone blocks were universally regarded as the best permanent support for the rails, wherever they could be laid upon a solid and durable foundation, and wooden sleepers were only resorted to as temporary supports, to be ultimately superseded by stone blocks whenever the foundation of the road should be properly consolidated. Opinion has, however, undergone some change on this subject, and wooden sleepers are now sometimes used in preference to stone blocks for permanent purposes: whether they will prove economical, when submitted to the trial of a long period of time, experience alone can decide.

The chairs which are the immediate supports or props on which the rails rest are attached to the centre of the upper surfaces of the blocks in the following manner:—Two holes are drilled in the blocks to a sufficient depth, about 2 inches in diameter, into which plugs of oak or other hard wood are driven; holes are then bored in these 3-8ths of an inch in diameter, corresponding in position with two holes in the chair of cast iron, which is to support the rail. Iron pins of half an inch in diameter are then driven through the holes in the chairs into the holes in the block, a piece of patent felt being placed between the chair and the block; and the chair is thus firmly fastened to the block.

The chairs are formed of cast iron, formed with a cavity corresponding to the magnitude and form of the rail: they vary very much in their size and form, according to the opinion or judgment of the engineer. A cross vertical section of one of the most common forms of chair, fixed on a block, now in use, with the rail resting in it, is represented in fig. 10.

(10.)



A great variety of expedients have been resorted to to maintain the rail fixed in its position in the chair. Pins and wedges of iron were first used of various forms, and applied in various ways. These, however, have now been very generally superseded by the simple contrivance of a wooden block or wedge driven in between the side of the chair, as represented at *a*, fig. 10. These wedges are prepared by previously passing them through a hydrostatic press, so as to harden them by exposing them to a severe pressure. Besides affording a very effectual fastening to the rail in the chair, these wedges, from the nature of the material, soften the jar which attends the transition of the wheels over the chairs.

Weight and Form of Rails. — The weight and form of the rails have been subject to great variation, since the extension of railways to the rapid transport of passengers. This has not arisen so much from ignorance of the mechanical properties of the metal thus applied, as from the varying weight and speed of the engines and loads transported upon them. The weight of the engines was, in the commencement, limited to 6 tons; but the most common weight of these machines at present is 12 tons; and their speed, as well as the amount of loads which they draw, have undergone a corresponding increase. The strength and solidity of the structure on which this extraordinary traffic is carried have necessarily undergone corresponding changes. The Liverpool and Manchester railway was first laid down with rolled iron rails, weighing 35 pounds per yard, supported on chairs 3 feet asunder. These were, however, soon found insufficient in strength, and they were replaced by rails weighing 50 pounds per yard, supported on bearings at the same distance asunder.

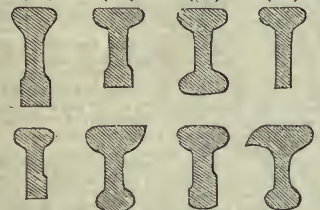
The distance between the bearings or chairs has also been subject to change. The necessary strength or weight of the rail will evidently depend on this distance; the greater the distance between the props, the greater must be the strength of the rail; and, so far as regards expense, the engineer has to balance the cost of heavier rails against the saving effected by a diminished number of blocks and chairs. But, independently of the consideration of expense, the effect upon the carriages and engines is to be considered. Between chair and chair, a slight flexure of the rail takes place, and the wheels have consequently to pass over a series of eminences, so as to give to the carriages a pitching motion, the intervals and degree of which must depend conjointly on the strength of the rails and the distance between the chairs.

The least distance between the chairs now used is 3 feet, and the greatest 5 feet; 50 lb. rails are very generally used on 3 feet bearings; 65 lb. rails on 4 feet bearings; and 75 lb. rails on 5 feet bearings. All these varieties of construction are used in different parts of the Liverpool and Manchester railway. The

Grand Junction railway, extending from Birmingham to Newton, is laid down uniformly with 65 lb. rails on 4 feet bearings, and the London and Birmingham railway has in different places all the above varieties.

The form of the rail has been much varied. The fish-bellied rail was considered to have the most advantageous form, when the Liverpool and Manchester railway was first brought into operation, and for some years afterwards. This form gives increased depth to the rail at the parts most distant from the supports; and, in theory, it is unquestionably the most correct, the strength of every part to resist vertical pressure being the same. But various practical objections have been found against it, which our limits will not allow us to examine or discuss; and the fish-bellied rail has accordingly been altogether superseded by the parallel rail, which is a rail whose cross section is the same at every part. Nothing can be more varied or more capricious than the forms given to the cross section of rails by different engineers. The figures 11 to 18. represent a few of this great variety.

(11.) (12.) (13.) (14.)

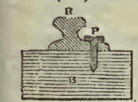


(15.) (16.) (17.) (18.)

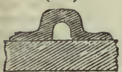
The form, however, which has obtained most general favour at the present time is that which is represented in fig. 13., the cross section of which is nearly the same as the longitudinal section of a dumb bell. This form of parallel rail has the advantage of being capable of being reversed, either side being turned upwards.

In some rare instances, modern railways in England have been laid down on *continuous bearings*. The rails, in such cases, are supported immediately on the longitudinal truckers without chairs. This is the case in the Manchester and Bolton railway, and in the Great Western railway: a section of a rail, as attached to a longitudinal trucker support without a chair, is represented in fig. 19., where R is a section of the rail, P an iron pin attaching it to the trucker B. These pins are placed at regular distances along the outside base of the rail.

(19.)



(20.)



A section of the rail with its trucker support, used on the Great Western railway, is given in fig. 20. These rails are fastened to the truckers by screws on each side. They weigh from 40 to 50 lbs. per yard.

Gauge of the Railway.—The gauge, or the distance between the rails, on which depends the distance between the wheels of the carriages and engines, and to a certain extent their structure, has recently been a subject of much discussion. It is contended by some that all railways constructed in the same country ought to have the same gauge; that, though it is not contended that the gauge now in use is the best that could possibly have been adopted, yet that, extensive lines of road having been constructed with that gauge, more disadvantage will attend any departure from it than could be balanced by any advantages that could attend any other magnitude of gauge.

In the colliery railways in the north of England, the rails had been laid at 4 feet 8½ inches asunder; and on the Liverpool and Manchester railway, the first line intended for general traffic, was laid down by Mr. Stevenson with the same gauge. The lines of railway subsequently projected, extending from Liverpool and Manchester to Birmingham (and thence to London), to Preston, Wigan, Bolton, Leeds, and other places, were laid down with the same gauge, since the carriages and engines would necessarily have to pass from one to the other. But when railways began to be constructed in Belgium and other parts of the Continent, where the same reason for uniformity of gauge did not prevail, the same gauge nevertheless was adopted. The first conspicuous departure from this uniformity took place in the Great Western railway, extending from London to Bristol, which was laid down with a gauge of 7 feet; and the Eastern Counties railway next adopted a gauge of 6 feet.

The gauge of a railway can be regarded as nothing more than its linear modulus, or the index to its general scale. There is nothing *per se* to give one gauge a preference over another; but, as the magnitude of the gauge determines the general magnitude and scale of the railway, and of every thing connected with the railway, including waggons, coaches, and engines, bridges, viaducts, tunnels, cuttings, &c., and, in short, all the works, whether of a moveable and perishable or fixed and permanent nature, it is a matter of the greatest importance that it should be determined with a just regard to the traffic of the line.

Curves on Railways.—With a view to insure the public safety, the legislature has generally required that no curve shall be allowed upon a main line with a less radius than one mile: the exceptions to this are where one railway passes into another; and at the termini, or the entrance of depôts or stations. In such situations the trains must slacken their speed, and therefore a sharp curve is attended with less danger. It has appeared, however, that these restrictions upon the radii of curves have been more stringent than safety requires. In a course of experiments made by Dr. Lardner, within the last two years, it has been established that curves of a mile radius produce no sensible increase of resistance at the usual speed of railway trains, and therefore curves of considerably less radius may be traversed at that speed without danger. We may here state, that on the Newcastle and Carlisle railway there are many curves in the main line with radii under half a mile, which are traversed at the usual speed with perfect safety.

Motive Power on Railways.—The motive power on railways for general traffic is at present steam power, and is either locomotive engines, which move along the railway with the load which they draw; or stationary engines, which, by means of ropes extended along the line of railway, draw the loads in either direction. *See* LOCOMOTIVE ENGINE and STATIONARY ENGINE.

Resistance of Air to Railway Trains.—Until very recently, it has been considered by engineers that the resistance to railway trains was almost entirely due to friction and mechanical effects, and that that part of the resistance which depends on the atmosphere formed so inconsiderable a portion of the whole that it might be disregarded in practice. The result of a course of experiments, made within the last two years, by Dr. Lardner, the details of which may be seen in the *Proceedings of the British Association*, have, however, indicated a serious amount of resistance due to the air. If Dr. Lardner's conclusion shall be confirmed by further experience, the great expense attending the maintenance of very high speed on railways, and the improbability of attaining in the ordinary work of a line the extraordinary velocity which some persons now contemplate, will be apparent.

Speed of Railway Traffic. *See* LOCOMOTIVE ENGINE.

For the details of the structure and operation of railways, see the Treatise by Nicholas Wood, 3d edition, London, 1838; *The Steam Engine, &c.*, by Dr. Lardner, 7th edition, London, 1840.

RAILWAY, PNEUMATIC or ATMOSPHERIC. The name given to a system of locomotion on railways by means of the pressure of the atmosphere. A simple and ingenious apparatus for this purpose was invented a few years ago, and is now being exhibited on the West London Railway at Wormwood Scrubs. Those who desire to see a brief though clear account of this invention, with a resumé of the advantages likely to accrue from its being generally adopted, may consult the well-reasoned letter of Mr. Pim, addressed to the President of the Board of Trade (1841). (See also a treatise on this subject, by Mr. Samuda.)

RAIN. (Ger. regen.) In Meteorology, water falling from the atmosphere in drops.

The theory of rain is not yet very satisfactorily established. One of the most ingenious explanations, and indeed the only one which rests entirely on known principles, was proposed by Dr. James Hutton in the *Philosophical Transactions of Edinburgh* for 1787. It is now a well-ascertained fact, though it was only matter of conjecture to Dr. Hutton, that the capacity of air for moisture, or the quantity of moisture which a given volume of air will hold, increases with the temperature, but in a much faster ratio than the temperature; and hence it follows that if two equal portions of air at different temperatures completely saturated with moisture are mingled together, a precipitation must take place in consequence of the mixture, which will have the mean temperature of the two portions, being unable to sustain the mean quantity of vapour. For example, suppose that while the temperature increases in an arithmetical ratio, the capacity for retaining moisture increases in a geometrical ratio, and that at the temperature of 15 centesimal degrees air can hold 200 parts of moisture; then at 30 degrees it will hold 400 parts, and at 45 degrees 800 parts. Now, suppose two equal bulks of damp air, at the respective temperatures of 15 and 45 degrees, to be mixed together, the compound must contain 1000 parts of vapour, or either half of it 500 parts; and the temperature of the compound will be 30 degrees. But at this temperature the air is saturated with 400 parts, and consequently there will be a precipitation of 100 parts from each of the given bulks.

It is obviously not necessary that the commingled por-

tions of air should be fully saturated with moisture, as assumed in the above example; rain will be precipitated if the two masses approach the point of saturation, but the quantity will be proportionally less. It is also a consequence of the theory that for a given difference of heat the precipitation will be greatly increased at the higher temperatures; and this is conformable to experience, for showers are most copious during hot weather, and in tropical countries. The circumstances, therefore, on which, according to this theory, the quantity of rain precipitated in a given time depends are the following:—The previous dampness of the commixed portions of air; the difference of their respective temperatures; the elevation of their mean temperature; and the extent to which the combination takes place.

The principal objection to this theory is, that the quantity of rain which actually falls in a given portion of time is often very much greater than can be supposed to be produced by any probable extent of cooling that can take place in the free atmosphere in that time, unless, perhaps, we have recourse to the supposition of a cold and warm current driving swiftly in opposite directions, and continually mixing their conterminous surfaces. Sir J. Leslie (*Encyc. Brit.*, art. "Meteorology") computes that if two currents of moist air were driving along in opposite directions, with velocities whose sum is 30 miles an hour, the one having a temperature of 70° of Fahrenheit, and the other of 50°, the deposition of moisture in the space of an hour would be equal to the height of an inch. If the sum of the opposite velocities amounted to 60 miles an hour, and the intermingling influence extended to but a quarter of an inch at the grazing surfaces, there would still be produced in the same time a fall of rain reaching to half an inch in altitude. These quantities agree sufficiently with observation in certain cases; but the objection still recurs that rain frequently falls from clouds which appear to move very slowly, and when consequently the supposition of such velocities is inadmissible.

It is the opinion of Mr. Luke Howard, and some other writers on meteorology, that Dr. Hutton's theory is insufficient to explain the phenomena; and that the immediate cause of rain is to be ascribed, in many instances at least, to the electric action of the clouds on each other. They suppose the hygrometric moisture in the air to be kept suspended by the mutual repulsions of the electric atmospheres of the particles; and that when the electricity is from any cause withdrawn, the suspending power is likewise removed, and the particles coalesce and fall in consequence of their gravity. That rain is connected in some way or other with the electric state of the atmosphere, is a position which may be readily conceded; but as the disturbance of the electric equilibrium remains to be accounted for, this theory, as it at present stands, brings us no nearer to definite ideas.

Some extraordinary falls of rain have been recorded, the accounts of which, if not given on apparently unexceptionable testimony, would scarcely fail to be regarded as fabulous. On the 25th October, 1825, a fall of 30 French inches (32 English), within 24 hours, occurred at Genoa; and on the 9th October, 1827, there fell at Joyeuse, in the south of France, a quantity equal to 31 English inches within the space of 22 hours. (Prof. Forbes's Report on Meteorology, in the *Reports of the British Association for* 1840.)

A curious circumstance attending the fall of rain is, that the quantity collected in rain gauges placed at the surface of the ground is considerably greater than when the instruments are placed at some elevation above the surface. On an average of 13 years the quantity of rain which fell annually in the court of the observatory at Paris was 56 centimètres (22 English inches); while the mean quantity which fell on the terrace, at the height of 28 mètres (92 feet) above the court, was only 50 centimètres, or 8-9ths of the former quantity. A gauge placed on the top of York Minster, at an elevation of 212 feet 10 inches, showed a fall of 14·963 inches between February 1833 and February 1834; while two perfectly similar instruments, one placed on the top of the Museum of that city, at a height of 43 feet 8 inches, and the other on the ground, gave respectively 19·852 inches and 25·706 inches. (*Reports of the British Association for* 1834.) It is supposed that this phenomenon depends, in some measure at least, on the circumstance that the drops of rain, descending from the higher regions with the temperature belonging to the elevation, cause a condensation of vapour in the lower strata, and probably of fogs, which are always denser near the surface of the ground, and which yield a considerable deposition of water. Any hypothesis of this kind, however, is quite insufficient to explain the great difference observed at York between the products of the rain gauges on the ground and the top of the Minster, and which is most probably to be ascribed to some imperfection in the action of the instrument when exposed to gales of wind. It has been suggested that eddies are formed round the rim of the funnel, which have the effect of diverting part of the rain.

Rain drops vary in size from perhaps the 25th to the 3d part of an inch in diameter; and, like other falling bodies, descend with a continually accelerating velocity until the resistance of the air becomes equal to their weight, after which the descent is uniform. The terminal velocity is proportional to the square root of the diameter of the drop; but it is perhaps not possible to determine with certainty the actual terminal velocity corresponding to a drop of any given diameter.

The average quantity of rain which falls in a year at any given place depends upon a great variety of circumstances,—as latitude, proximity to the sea, elevation of the region, configuration of the country and of the mountain ranges, exposure to the prevailing winds; and in general on the different local causes which influence climate. Humboldt estimates that the average depth of rain which annually falls at the latitudes of 0°, 19°, 45°, and 60°, may be taken respectively at 98, 80, 29, and 17 inches; but this estimate must be regarded rather as a rough approximation to the ratio in which the quantity decreases on going from the equator, than as indicating the actual averages at any particular place; and it is observed that though the annual depth be greatest towards the equator, the number of rainy days in the majority of places increases with the latitude.

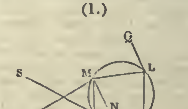
The greatest depth of rain which has been registered at any place in a year is at Maranham, lat. 2½° S., and which is stated by Humboldt to be 277 English inches. But this is greatly above the average, and indeed more than double the annual quantity which has been observed at any other locality. At St. Domingo the annual fall is estimated at 120 inches; at Cayenne, 116 inches; in the island of Granada, 112; at the Havannah, 91; at Calcutta, from 76 to 118; at Bombay, from 83 to 96; the island of Martinique, 87 inches; and at Sierra Leone, 86. Of European countries, Portugal appears to be the most humid, 123 inches having been observed at Coimbra in a year. The average depth at Paris is 19·1 inches (Arago, *Journal de Physique*, 1816); Berlin, 20·9; Brussels, 19; Florence, 41·3; Lyons, 39·5; Maestricht, 36·1; Marseilles, 18·4; Padua, 36·6; Petersburg, 18·2; Rome, 31·2; Rotterdam, 22·4; Stockholm, 18·7; Vienna, 17. For places in Great Britain the following averages were deduced by Dr. Dalton from observations of a number of years:—Manchester, 36·140 inches; Liverpool, 34·118; Lancaster, 39·714; Kendal, 53·944; Dumfries, 36·918; Glasgow, 21·331; London, 20·686. Mr. Howard gives the annual average at London equal to 24·9 inches; Professor Phillips at York, 25·7; and Mr. Adie at Edinburgh, 25 inches. (On the theory of rain, see Kämptz, *Lehrbuch der Meteorologie*; Muncke, in *Gehler's Physicalisches Wörterbuch*; *Daniell's Meteorological Essays*, &c.)

RAINBOW. (Germ. regenbogen; Lat. iris; Fr. arc en ciel.) The brilliant-coloured arch which makes its appearance when rain is falling in the region of the sky opposite to the sun, and the sun is shining at the same time.

This well-known meteor presents, when perfect, the appearance of two concentric arches; the inner being called the *primary*, and the outer the *secondary* rainbow. Each is formed of the colours of the solar spectrum; but the colours are arranged in the reversed order, the red forming the exterior ring of the primary bow and the interior of the secondary. The innermost bow is a segment of a circle whose radius subtends an angle of about 42°; the radius of the outer subtends an angle of about 51°; and the common centre is situated in the prolongation of the straight line which passes through the centre of the sun and the eye of the spectator. From the conditions invariably accompanying its appearance, the colours of the rainbow were known at an early period to be produced by the sun's rays passing through the drops of falling rain; but the phenomenon is a complicated one, and was not fully and satisfactorily explained until Newton had discovered the compound nature of solar light, and the different refrangibility of the component rays.

In order to explain the phenomenon of the rainbow, let us suppose a beam of light admitted through a small hole in the shutter of a darkened room to fall on a spherical globule of water at I (fig. 1.) in the direction S I, and trace the path of the light in the interior of the globule. On entering the globule at I it is refracted, and consequently decomposed, the rays of each colour being deflected under a different angle from its original direction. For the sake of perspicuity, we shall confine our attention to the red ray. Let I K be the direction of the ray after the first refraction. On meeting the surface of the drop at K a portion of the light will effect its escape, and be again refracted in the direction K P, while the remaining portion will be reflected by the surface in the direction K L, the lines I K, K L making equal angles

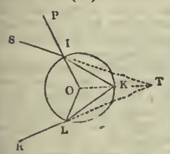
(1.)



with a tangent at K. But on arriving again at the surface at L, this portion of the ray which was reflected from K will be again divided into two parts; one part will escape at L, and be refracted in the direction L Q, while the other part will be reflected by the surface, and proceed in the direction L M. At M the phenomenon will be repeated; part of the remaining light will escape and be refracted in the direction M R, and the other be reflected in the direction M N. This process will be repeated indefinitely; but the intensity of the light is diminished at each successive impact, and after a few reflexions the quantity which emerges becomes insufficient to make an impression on the eye. All this may be shown experimentally by causing a beam of light to fall upon a glass cylinder filled with water, and placed in a darkened room; the red light emerging at the points K L M will be seen when the eye is placed in the straight lines K P, or L Q, or M R.

To apply this experiment to the explanation of the rainbow, it is necessary to determine the inclination of the emerging to the incident ray. We shall first take the case of two refractions with a single intermediate reflexion. Let S I (fig. 2.) be the incident ray, I K the direction after the first refraction, K the point of reflexion, L the point of emergence, and L R the direction of the emerging ray; also let S I and R L be produced to meet in T. The angle S T R is called the angle of deviation, and the object is now to find an expression for its value in terms of the angle of incidence. Let O be the centre; draw O I P and O L, and join O T, which will evidently pass through K. Let us now assume,

(2.)



$i = $ O I T $=$ S I P the angle of incidence,
$r = $ O K I $=$ O I K the angle of refraction,
D $=$ S T R the angle of deviation;

then, since O K I $=$ K I T $+$ K T I, and K I T $=$ O I T $-$ O I K, we have $r = i - r + \frac{1}{2}$ D, whence

$$D = 4r - 2i \quad . \quad . \quad . \quad . \quad (1.)$$

Here D is expressed in terms of r and i; but by the theory of refraction we have also the relation

$$\sin. i = n \sin. r \quad . \quad . \quad . \quad . \quad (2.)$$

(where n is the index of refraction for the red ray), so that the value of D depends only on that of i.

The angle of incidence, i, may have any value between 90° and 0. But it is obvious that between those values D must have a maximum; for when S I falls perpendicularly on the globule there is no deviation, and when S I merely touches the globule the deviation again vanishes. To find the determinate value of i at which the maximum takes place, differentiate the equation (1.), and make the differential of D equal to zero; this gives $d\,i = 2\,d\,r$. Equation (2.) also gives $\cos. i\,d\,i = n \cos. r\,d\,r$; whence we obtain, by eliminating $d\,r$, and dividing both sides of the resulting equation by $d\,i$, $n \cos. r = 2 \cos. i$. On substituting for $\cos. r$ in this equation its value found from (2.), the following expression is obtained: —

$$\cos. i = \sqrt{\tfrac{1}{3}\,(n^2 - 1)}.$$

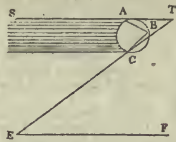
This is the value of i corresponding to the maximum deviation expressed in terms of n. But in respect of the red rays, the value of n is found experimentally to be $108 \div 81 = 1{\cdot}3333$; and the corresponding value of i given by the trigonometrical tables is $i = 59^\circ\ 23'\ 30''$. From this the values of r and D are readily deduced; and the three values are as follows: —

$$i = 59^\circ\ 23'\ 30'',\ r = 40^\circ\ 12'\ 10'',\ D = 42^\circ\ 1'\ 40''.$$

The next step towards the explanation of the phenomenon is, to show that no other light than that which falls on the drop under the angle of incidence corresponding to the greatest deviation, will be refracted in sufficient quantity to make a sensible impression on the eye. Now since S I is the incident ray, with respect to which the deviation is a *maximum*, the rays which are situated very near to S I, on either side, will enter the drop at very nearly the same angle of incidence, and consequently will emerge very nearly parallel to L R. With respect then to the pencil of light which falls on the drop at the angle of incidence, corresponding to the maximum deviation, all the rays of red light which it contains, and which emerge after the first reflexion, will on their emergence be parallel, and enter the eye situated in the straight line L R in sufficient number to make a vivid impression on the retina. But with respect to a pencil falling on the drop at a small distance from I, and consequently under a different angle of incidence, the red rays at their emergence will not be parallel, but divergent; and the light will consequently diminish in intensity as it recedes from the drop, and at the distance of the spectator will be much too faint to produce a distinct impression. It is on this delicate principle that the phenomenon principally depends.

The above principles being clearly understood, all the circumstances of the phenomenon admit of easy explanation. Let A B C (fig. 3.) be a section of a drop of rain made by the plane passing through the centre of the sun, the centre of the drop, and the eye of the spectator; and suppose the rays from the sun's centre to fall on it in the direction S A. Let E be the position of the eye of the spectator, whose back is turned towards the sun, and draw E F parallel to S A. Now suppose the line E T to be drawn so as to make with E F an angle of 42° 1′ 40″, and to meet the drop at C; then, since the whole of the anterior surface of the drop is illuminated by the rays S A, some one of those rays must fall on it under an angle of incidence, such that after being refracted at A, reflected at B, and again refracted at C, it will emerge parallel to C E, and consequently make with E F the maximum angle of deviation. The spectator will therefore see the red colour of the spectrum in the direction E C. But it is obvious that all these conditions will be fulfilled in respect of every drop of rain which the line E C will meet, on supposing it to revolve about E F as an axis at the same angle of inclination. Hence the red rays thus refracted form the surface of a cone, the axis of which is the prolongation of the straight line drawn from the centre of the sun to the eye; and as the eye of the spectator is at the apex of the cone, a circular segment of red light will be visible, the other part of the circle being cut off by the horizon.

(3.)



What has now been said has reference only to rays coming from the sun's centre; but the same thing must happen with respect to rays coming from every point of the sun's disk; and as the sun's diameter subtends an angle of about 30′, the spectator will consequently see a band of red light of the breadth of about 30′.

The explanation which has now been given of the appearance of the red light applies to all the other colours of the spectrum, the only difference being in the value of the index of refraction. For the violet ray, in passing from air to water, the index is $109 \div 81$; we have therefore $n = 1{\cdot}3468$; and on computing from this the values of i, r, and D, by means of the preceding formulæ, there results, appproximately,

$$i = 58^\circ\ 40'\ 3'',\ r = 39^\circ\ 24'\ 20'',\ D = 40^\circ\ 17'.$$

In this case, therefore, the angle of maximum deviation is less than for the red ray, and hence the violet is within the red. The breadth of the violet band will obviously be the same as that of the red, as both depend on the same cause; namely, the magnitude of the sun's apparent diameter.

As the red and violet are the rays whose indices of refraction are the least and greatest respectively, all the other prismatic colours will lie between these two, and occupy bands of the same breadth, but with considerable blending into each other; for the distance between the centre of the red and the centre of the violet, being equal to the difference between their respective angles of maximum deviation, amounts only to $42^\circ\ 2' - 40^\circ\ 17' = 1^\circ\ 45'$. The whole breadth of the interior or primary bow is this quantity plus the sun's apparent diameter, or about 2° 15′.

The size of the bow depends upon the height of the sun above the horizon. When the sun is in the horizon, the bow will be a semicircle to a spectator on a plane; but on the summit of a mountain, he may see a segment greater than a semicircle.

We have now to explain the formation of the exterior bow. In this case, the light suffers two reflexions in the interior of the globule, and the path of a ray, as represented in fig. 1., is S I K L M R. If we denote the angle of deviation, or the angle formed by S I and M R, the incident and emerging rays by D′, and take as before i and r to represent the angles of incidence and refraction, it is easy to find the equation,

$$D' = 6r - 2i - 180^\circ.$$

On proceeding from this by the same method as before to find the value of i corresponding to the *maximum* value of D′, the following equation is obtained: —

$$\cos. i = \sqrt{\tfrac{1}{8}\,(n^2 - 1)}.$$

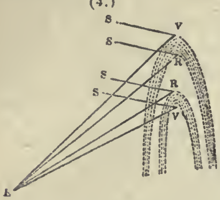
Substituting for the constant n its values in respect of the red and violet rays, the values of i, and consequently of r and D′, are obtained. They are as follows: —

red, $i = 71^\circ\ 50'$, $r = 45^\circ\ 27'$, $D' = -50^\circ\ 59'$;
violet, $i = 71^\circ\ 26'$, $r = 44^\circ\ 47'$, $D' = -54^\circ\ 9'$;

the minus sign indicating that the incident and emergent rays intersect before the drop.

From these values it appears that in the case of the exterior bow the deviation is least in respect of the red ray, and greatest in respect of the violet; the order of the colours is therefore reversed, the red occupying the innermost band, and the violet the outermost, as represented in fig. 4., where E R is the red and E V the violet ray, the eye of the spectator being at E. The breadth from the middle of the red to the middle of the violet is 3° 10′, or nearly double that of the interior bow. The interval between the red of the interior bow and the red of the exterior is 50° 59′ — 42° 2′, or 8° 57′. All these values, deduced as above from the theory of refraction, are found to agree exactly with those found by actual measurement.

(4.)



Dr. Halley, in the *Phil. Trans.* for 1700, has computed the diameters of the rainbows formed by three, four, and five reflexions; but these bows are rarely if ever seen, the light being too faint to make an impression on the eye. Supernumerary or spurious rainbows are sometimes seen within the primary and without the secondary bow, and having the same order of colours as the bows to which they respectively belong. They are explained by Dr. Young on the theory of the interference of light. (*Phil. Trans.* 1804; *Lect.*, vol. i. p. 470.) An inverted or distorted iris is sometimes observed lying on the ground, formed by the drops of dew suspended from the tops of the blades of grass, or from spiders' webs. In favourable circumstances lunar rainbows are sometimes seen; but their colours are faint and scarcely perceptible.

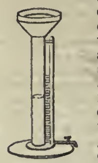
The first explanation of the true theory of the rainbow is usually ascribed (see *Newton's Optics*) to Antonio De Dominis, archbishop of Spalatro, whose work, *De Radiis Visus et Lucis*, was published at Venice in 1611, but stated to have been written twenty years previously. It would appear, however, from the account of this work given by Boscovich, Montucla, Priestly, and Biot, that the merit of De Dominis was confined to a vague statement or surmise, unsupported by experiment, that the interior bow is formed by two refractions and an intermediate reflexion. He gave no reason for the precise angle which its diameter subtends; and with respect to the exterior bow, his attempt to explain its formation is wholly erroneous. The true theory of the exterior bow, and the determination of the particular angles of deviation under which alone the rays transmitted to the eye are sufficiently dense to be visible, belongs to Descartes. The explanation given by Descartes, in his *Dioptrics*, is complete in every respect, excepting as to the cause of the colours, the theory of which was supplied by Newton's great discovery of the unequal refrangibility of the different rays. (See Montucla, *Histoire des Mathematiques*, vol. i. p. 700.; *Priestly on Vision*, p. 107.; *Biot, Traité de Physique*, tom. iii. p. 460.)

RAIN-GAUGE, also called OMBROMETER, UDOMETER, and PLUVIAMETER. An instrument for measuring or *gauging* the quantity of rain which falls at a given place.

"The *rain-gauge* may be of very simple construction. A cubical box of strong tin or zinc, exactly 10 inches by the side, open above, receives at an inch below its edge a funnel, sloping to a small hole in the centre. On one of the lateral edges of the box, close to the top of the cavity, is soldered a short pipe, in which a cork is fitted. The whole should be well painted. The water which enters this gauge is poured through the short tube into a cylindrical glass vessel, graduated to cubic inches and fifths of cubic inches. Hence, one inch depth of rain in the gauge will be measured by 100 inches of the graduated vessel, and 1-1000th inch of rain may be very easily read off.

"It is very much to be desired that, being of such easy construction, more than one of these gauges should be erected; or at least one placed with its edge nearly level with the ground, and another upon the top of the highest building, rock, or tree in the immediate vicinity of the place of observation, the height of which must be carefully determined, it having been satisfactorily ascertained that the height of the gauge above the ground is a very material element of the quantity of rain which enters it. The quantity of water should be daily measured and registered at 9 A. M." (*Report of the President and Council of the Royal Society on the Instructions to be prepared for the Scientific Expedition to the Antarctic Regions*, 1840.)

A convenient form of the instrument is represented in the annexed figure, where the rain which enters the funnel is collected in a cylindrical vessel of copper, connected with which at the lower part is a glass tube with an attached scale. The water stands at the same height in the cylinder and glass tube, and being visible in the latter, the height is read immediately on the scale; and the cylinder and tube being constructed so that the sum of the areas of their sections is a given part, for instance a tenth, of the area of the funnel at its orifice, each inch of water in the tube is equivalent to the tenth of an inch of water entering the mouth of the funnel. A stop-cock is added, by which the water is drawn off when the observation is made.



RAISING PLATE, or UPPER PLATE. In Architecture, the plate or longitudinal timber on which the roof stands raised or placed.

RA'JAH. The hereditary princes of the Hindoos are so termed. They belong to the caste of warriors, or Cshatriya, and are generally dependent on Europeans, except in those parts of the country which the European arms have not as yet penetrated. *See* CASTE.

RAKE, TO. The sea term for *incline*, and applies to the masts, stem, and stern-post, &c.; the bowsprit, instead of raking, is said to *steeve*. Masts generally rake aft, and in peculiar rigs only forward. The rake of the mast has an influence on the sailing of the vessel, and the masts of some schooners rake excessively. The principal effect seems to be to diminish the effect common to all the sails, of depressing the ship's head.

To *rake a ship*, is to fire into her head or stern in the direction of her length, or along her decks. It is similar to what engineers term enfilading.

RAM. In Hydraulics. *See* HYDRAULIC RAM.

RAMADAN, or RHAMADAN. The name given to the great fast or Lent of the Mohammedans. It commences with the new moon of the ninth month of the Mohammedan year; and, while it continues, the day is spent uninterruptedly in prayers and other devotional exercises. Even the night is passed by the more rigid of the faithful in the mosques, which are splendidly illuminated on this occasion; but, generally speaking, the arrival of sunset is the signal for a more than usually unlimited indulgence in the pleasures of the table; and, on the third evening of the fast, the grand vizier commences a series of official banquets. The Ramadan ends on the day preceding the only other great festival of the Mohammedans, — the *Bairam* (which see), equivalent to our Easter.

RAMAYA'NA (Sanscr. *the Career or Travels of Rama*), the oldest of the two great Sanscrit epic poems, describes the life and actions of the hero Rama, and his wife Sita; and especially Rama's expedition to Ceylon, to rescue Sita from the tyrant Rawana. The poem is thought to have been composed before the Christian era; but there is no certain indication of its age. A translation of it was commenced by Messrs. Carey and Marshman (printed at Serampore); and another by A. W. von Schlegel (Bonn, 1829).

RAM, BATTERING. *See* BATTERING RAM.

RAME'NTA. In Botany, thin, brown, foliaceous scales, appearing sometimes in great abundance upon young shoots, and particularly numerous and highly developed upon the petioles and the backs of the leaves of ferns.

RA'MISTS, or RA'MEANS. In Philosophy, the partisans of Pierre Ramé, better known by his Latin name of Ramus, royal professor of rhetoric and philosophy at Paris in the reign of Henry II. He perished in the massacre of St. Bartholomew. His system of logic was opposed to that of the Aristotelian party; and during the latter half of the 16th century a vehement contest was maintained between their respective adherents in France, Germany, and other parts of Europe. (Hallam, Introduction to the *Literature of Europe*, vol. ii. ch. 3.) "He conferred," says the same writer, "material obligations on science by denying the barbarous method of the schoolmen. What are the merits of his own method, is a different question." (*Ib.* vol. i. ch. 7.)

RAMNE'NSES, or RAMNES. The name of the first century of the 300 horsemen who constituted the cavalry of Rome under the early kings. Most probably the name also applied at first to the original century of patrician houses established by Romulus, and distinguished them from the Tatienses and Luceres; whose names, in like manner, must be supposed to extend not merely to the two remaining centuries of cavalry, but to the two centuries of tribes respectively instituted by Romulus, on the accession of the Sabines and Tarquinius Priscus. (See the histories of Niebuhr and Arnold.)

RAMP. (Fr. Rampe.) In Architecture, a concave bend or slope in the cap or upper member of any piece of ascending or descending workmanship.

RA'MPANT. (Fr.) In Heraldry, a term used to

describe lions, tigers, bears, &c., when represented as standing erect on their hind legs.

RA'MPART, or RAMPIER. In Fortification, the wall which surrounds a fortified place. It is built of the earth taken out of the ditch; though the lower part of the outer slope is usually constructed of masonry. The advantage of earth is, that the balls instead of splintering the work, and rebounding in various directions to the great injury of the besieged, pass forward into the earth, and bury themselves there. This also renders the rampart of earth much more durable under the fire of the besiegers than masonry would be. The usual height of the rampart is about three fathoms, and its thickness about ten or twelve feet. *See* FORTIFICATION.

RAMS' HORNS. In Fortification, the name given by Belidor to the tenailles. *See* TENAILLE.

RA'NA. (Lat. *a frog.*) The generic name of the tailless Batrachian reptiles, which have the hind legs longer than the fore, and webbed toes fitted for swimming, and not expanded at the extremity. Their head is flat, muzzle rounded, and the opening of their jaws large; the tongue in most of them is soft, and not attached to the bottom of the gullet, but to the edges of the jaw, with the free end turned backwards. There are but four toes to the anterior feet; the hind ones frequently exhibit the rudiment of a sixth.

There are no ribs to their skeleton, and a prominent cartilaginous plate supplies the place of a tympanum, and renders the ear visible externally. The eye is furnished with two fleshy lids, and a third, which is transparent and horizontal, concealed under the lower one. Inspiration is effected by the muscles of the throat, which, by dilating, draw in air by the nostrils, and by contracting while the nostrils are closed by the tongue compel the air to enter the lungs; expiration, on the contrary, is produced by the muscles of the lower part of the abdomen. The young frog, which is called a tadpole, is at first furnished with a long fleshy tail, and a small horny beak, having no other apparent limbs than little fringes on the sides of the neck. These disappear in a few days, and the hind feet of the tadpole are very gradually and visibly developed; the fore feet are also developed, but under the skin, through which they subsequently penetrate. The tail is gradually absorbed. The beak falls and discloses the true jaws, which at first were soft and concealed beneath the skin; and the branchiæ are absorbed, leaving to the lungs alone the function of respiration in which they participated. The eyes, which at first could only be discerned through a transparent spot in the skin of the tadpole, are now visible with their three lids. Tadpoles reproduce their limbs almost like salamanders.

The period at which each of these changes takes place varies with the species. In cold and temperate climates, the perfect animal passes the winter under ground, or in the mud under water, without eating or breathing; though if it be prevented from respiring during the summer for a few minutes by keeping its mouth open, it dies.

RA'NDOM SHOT. A shot discharged with the axis of the gun above the horizontal or point blank direction.

RANGE, in Gunnery, is the horizontal distance to which a shot or other projectile is carried. Were it not for the resistance of the air, the path described by a projectile acted upon by the force of gravity would be a parabola; and the greatest range would be obtained by discharging the projectile at an angle of 45° of elevation. But by reason of the atmospheric resistance, the path actually described is very different from a parabola, and the elevation which gives the greatest range can only be determined by experiment. *See* GUNNERY, PROJECTILES.

RANGE. A certain quantity of cable drawn up out of the cable tied and laid along the deck, equal in length to the depth of water, in order that the anchor, when let go, may reach the bottom without being checked.

RA'NGER. Formerly a sworn officer of the king's forests, whose principal duty it was to see and inquire of trespassers in his bailiwicks, and present them at the next court holden for the forest; but now merely an officer of state. *See* FOREST.

RA'NIDÆ. The family of Batrachian reptiles, having as the type the frog (*Rana temporaria*, Linn.). *See* RANA.

RA'NTERS. A sect which originated in a secession from the Wesleyan connection, on the ground that the Wesleyans paid too much attention to order and decorum in the conducting of public worship, and that they were deficient in zeal in obtruding the gospel on the minds of the people by open preaching in the streets and fields. The ministers of this party parade the streets, preaching, singing hymns, and inviting the populace to come to their places of worship. They admit of female preaching; a thing unknown to every other body of Methodists. They are most prevalent in America. Their chapels are about 400 in number; their preachers, 2700; their members, 34,000. (*Bourne's Hist. of the Prim. Methodists.*)

RA'NULA. (Lat. rana, *a frog*, to which it has been supposed to bear some resemblance.) A tumour under the tongue, generally arising from some obstruction of the ducts of the salivary glands; when they break they are apt to leave a very troublesome ulcer.

RANUNCULA'CEÆ. (Ranunculus, one of the genera.) Exogenous Polypetalous plants, in almost all cases herbaceous, inhabiting the colder parts of the world, and unknown in hot countries, except at considerable elevations. They are of great importance, in consequence of their usually poisonous qualities, as evinced by aconite and hellebore in particular, which are the roots of several species. Some of them are objects of beauty, as the larkspurs, ranunculus, anemone, and pæony. A few are simply astringent, as the coptis or gold thread of North America. The plants of this order are readily known by having an indefinite number of hypogynous stamens, separate carpels, exstipulate undotted leaves, and an herbaceous stem.

RANZ DES VACHES. (Germ. Kuhreigen.) The name of the simple and beautiful melody which the Swiss herdsmen are in the habit of playing on the Alpine horn, and sometimes of singing, when they drive out their herds to the mountains. It consists of a few simple intervals, and has a beautiful effect in the echoes of the Swiss mountains. The natives regard it almost with rapture, and are said to be seized with irrepressible longings to return to their native country when they hear it played in a foreign land.

RAPE. (Lat. raptus.) In Criminal Jurisprudence, a well-known and detestable offence committed against women. This offence has been most properly viewed by all legislators as one of the gravest character, and has been usually visited with the highest penalties. The accusation of rape, it is true, is one that may be easily made, and is, no doubt, sometimes preferred in cases where consent has been given. The proof, therefore, should be clear in proportion to the enormity of the crime; but when proved it is one that should very rarely indeed escape the utmost vengeance of the law. Capital punishment for this offence was abolished in 1841.

RAPE. An Anglo-Saxon territorial division, of which the etymology is uncertain. Sussex is the only county divided into rapes; each containing three or four hundred. These subsisted as military divisions at the time when Domesday Book was compiled. They were formerly under the superintendence of "rasse-reeves," subordinate to the sheriff of the county.

RAPE. A plant belonging to the cabbage family (*Brassica rapa*, Linn.), cultivated in fields for its seeds, which are crushed for oil; and sometimes for its leaves, which are fed off by sheep. In Belgium another species or variety of Brassica is cultivated for these purposes, called *cobya*, the *Brassica oleifera* of De Candolle.

RAPHE. (Gr. ῥαφη, *a suture.*) In Botany, the vascular cord communicating between the nucleus of an ovule and the placenta, when the base of the former is removed from the base of the ovulum.

RAPHE. In Anatomy, a term applied to parts which look as if they had been sewed or joined together.

RA'PHIDES. (Gr. ῥαφη.) Certain needle-like transparent bodies found lying in the tissue of plants. They were formerly thought to be peculiar organs, but are now known to be the crystals of various salts.

RAPTO'RES. (Lat. raptor, *a robber.*) Rapacious birds, or raveners. The name of the order of birds called *Accipitres* by Linnæus and Cuvier, including those which live by rapine, and are characterized by a strong, curved, sharp-edged, and sharp-pointed beak; and robust short legs, with three toes before and one behind, armed with long, strong, crooked talons.

RAREFA'CTION. In Physics, an augmentation of the intervals between the particles of matter, whereby the same number of particles occupy a larger space. The term is chiefly used in speaking of the aëriform fluids, the terms *dilatation* and *expansion* being applied in speaking of solids and liquids. In the free atmosphere rarefaction is caused by diminishing the pressure, and hence the air becomes rarefied at elevations above the general level. The limits to which rarefaction may be carried are not known; but it has been proved by experiments with the air-pump, that air may be rarefied so as to occupy a volume 13,000 times greater than it occupies under the ordinary pressure.

RASKO'LNIKS. (Russ. raskolo, *a division.*) The name of the largest and most important body of dissenters from the Greek church in the Russian dominions. They designate themselves Starowerzi, or *the Orthodox;* but differ from the Greek church only in the outward forms of religion, and in maintaining a more strict ecclesiastical discipline. This body was formerly subjected to persecution; but it is now treated with comparative toleration, though its members are still excluded from the service of the state. Their number is said to be about 300,000.

RASO'RES. (Lat. rado, *I scratch.*) Gallinaceous birds, or scratchers The name of an order of birds, including those which have strong feet, provided with obtuse claws for scratching up grains, &c., and the upper mandible vaulted, with the nostrils pierced in a mem-

branous space at its base, and covered by a cartilaginous scale. *See* GALLINACEÆ.

RAT. The name of a large, destructive, and very prolific species of the genus *Mus* (*Mus decumanus*, Linn.), introduced into the British Islands from Asia; not, as is commonly believed, from Norway. It has spread over all the country, and multiplied at the expense of the old British species called the "black rat" (*Mus rattus*, Linn.). *See* MUS.

RA'TCHET, in Clock and Watch Work, is the name given to an arm or piece of mechanism, one extremity of which abuts against the teeth of a *ratchet wheel*, and the other extremity is either freely jointed to a reciprocating driver for the purpose of communicating a continuous motion to the wheel, or is attached to a fixed centre to ensure the wheel against reverse motion. In the former case it is also called a *click* or *paul*, in the latter a *detent*.

RA'TCHET WHEEL. A wheel having teeth formed like those of a saw, against which the ratchet abuts. *See* RATCHET.

RATE OF A SHIP, in the Royal Navy. The navy is divided into three classes. Rated ships, commanded by captains; sloops and vessels, by commanders; and the third class by lieutenants. Rated ships are divided into six classes:—1st, all three-deckers; 2d, two-deckers, having 700 men and upwards (war establishment); 3d, ships having from 600 to 800 men; 4th, ships having from 600 to 400 men; 5th, ships having from 400 to 250 men; 6th, ships having under 250 men.

Rate of sailing of a Vessel, is measured by the *log*, which see. Various plans have been proposed for this purpose by various forms of the log itself, by the rise of water in tubes communicating with the sea, and (by Captain Burney) by the pressure upon a body towed astern and pulling on a spring. But the violence and irregularity of the pull, and the uncertainty in reading the result, have probably combined to set aside this last plan, which, in theory, seems to promise some advantages; because the pressure, increasing as the square of the velocity, would show very small changes of velocity: for the same reason, however, the mean result shown in a heavy sea would be too great. A certain and simple method of ascertaining the velocity at any instant, with precision, is one of the most important desiderata towards the perfection of naval science.

RA'THOFFITE. In Mineralogy, a species of garnet found in Sweden, accompanied by calcspar and hornblende.

RATIFICA'TION. (Lat. ratum, *determined*, facio, *I make*.) The solemn act by which a competent authority gives validity to an instrument, agreement, &c. The term is ordinarily used in international law for the sanction given by governments to treaties contracted by their representatives. In French law, ratification is defined the approbation or confirmation of what has been done or promised. Thus, in many instances, a person, on attaining his majority, ratifies acts done by himself or his guardian in his minority. And ratification is either express or tacit; the latter resulting, by implication, from his silence for ten years after attaining his majority.

RA'TIO (Lat.), in Geometry, is defined by Euclid (*Elements*, book v. def. 3.) to be "a mutual relation of two *magnitudes* of the same kind to one another in respect of *quantity*." This definition has been much criticised. Dr. Barrow (*Lectiones Math.*) calls it a metaphysical definition, inasmuch as it is not properly a mathematical definition, since nothing in mathematics depends on it, or can be deduced from it; and supposes that Euclid had probably no other design in making it than to give a general summary idea of ratio to beginners. It has been remarked, that as the word *quantity* in our language, if not quite synonymous with magnitude, has a signification only a little more general, the definition as above rendered is either tautological or unmeaning. Dr. Simson supposes it to be the interpolation of some unskilful editor. Leslie (*Elements of Geometry*) ingeniously supposes that the Greek word πηλικότης, which is usually translated *quantity*, may have reference to *multitude* or number, as well as to magnitude, and that Euclid's definition may be rendered as follows:—"Ratio is a certain mutual habitude of two homogeneous magnitudes with respect to *quotity*, or numerical composition." Dr. Wallis (*Opera Mathematica*, tom. ii. p. 665.) translates the same word by the Latin *quantuplicitas*, which refers to the number of times the one magnitude is contained in the other. Dr. Peacock (*Algebra*, p. 309.) remarks, that there is no geometrical definition of ratio by which the equivalence of different modes of representation may be ascertained as necessary consequences; and for this reason, ratios in geometry are only considered in connection with each other, as constituting, or not constituting, a proportion. In arithmetic and algebra, a ratio may be defined as the fraction whose numerator is the antecedent, and denominator the consequent of the ratio; and hence, in those sciences, the theory of ratios become identified with the theory of fractions. (For an account of what has been written on the subject of geometrical ratios, see *Camerer's Euclid*, Excursus ad lib. v. Berlin, 1825.)

RA'TION. In the Army, a portion of food and ammunition, &c., distributed to each soldier for his daily maintenance. The rations of officers vary according to the number of servants in their pay.

RA'TIONAL. In Arithmetic and Algebra, an expression in finite terms; or one in which no extraction of a root is left; or, at least, none such indicated, which cannot be actually performed by known processes. The contrary of these are called *surd* or *irrational* quantities. Thus, 2, 9, $12\frac{1}{3}$, are rational quantities; and $\sqrt{2}$, $\sqrt[3]{4}$, &c., are irrational or surd quantities, because their values can only be approximately, and not accurately, assigned.

RATIONAL HORIZON. In Geography, the plane passing through the centre of the earth parallel to the *sensible horizon* of the place to which it is referred. *See* HORIZON.

RA'TIONALISM. The interpretation of scripture truths upon the principles of human reason; which has become famous in the present day by the theological systems to which it has given birth in Germany. The history of the progress of the opinions of the reformed churches of that country may be found in Dr. Pusey's essay upon this subject. He conceives the polemical discussions which prevailed throughout those communities in the 17th and first half of the following century to have prepared the way for the reception of the low views of Christianity, as a moral system, which were derived from the writings of the concealed or avowed deists of this country,—Herbert, Tyndal, Morgan, Toland, &c.; and from the tone with which they were reviewed by the sincere, but odd, theologians of the orthodox party. From the middle of the last century there has arisen in Germany a succession of divines—Baumgarten, Michaelis, Semler, Eichhorn, Paulus, Bretschneider, &c.—who have endeavoured either to affix a lower and more human character to the invisible operations of God upon men through Christianity, or to reduce the accounts which we have of the foundation of our religion to the mixture of truth and error natural to fallible men. They have questioned the genuineness of almost all the separate parts of Scripture, and the accuracy of all their supernatural narratives. The discredit into which these theologians appear to have fallen arises, in a great measure, from the inability they have shown to produce a connected and consistent system of religion upon the low ground which they have taken up. Of later years a much more spiritual conception of the nature of scripture promises and Christian assistances is observable in the writings of German divines, under the operation of which their theological criticism has already assumed a more dignified and exalted tone. The sensation created by Strauss's *Life of Christ*, the latest, and in some respects the most remarkable production of the Rationalist school, may probably have aided in this reaction. (See the article "Rationalismus," in the *Conv. Lexicon*. The English reader may consult the writings of Mr. Hugh Rose and Dr. Pusey on the subject of German rationalism; *Atkinson's View of Universities in Germany; Hawkins's Germany*, and two articles in the *Church of England Quarterly Review*, Oct. 1837, and Jan. 1838.)

RA'TLINES. Small horizontal lines or ropes extended over the shrouds, thus forming the steps of ladders for going up and down the rigging and masts. To *rattle* the rigging, is to fix these ratlines.

RATTANS, or CANES. The long slender shoots of a prickly bush (*Calamus rotang*, Linn.), one of the most useful plants of the Malay peninsula and the Eastern islands. They are exported to Bengal, to Europe, and above all to China, where they are consumed in immense quantities. For cane-work they should be chosen long, of a bright pale yellow colour, well glazed, and of a small size; not brittle or subject to break. They are purchased by the bundle, which ought to contain 100 rattans, having their ends bent together, and tied in the middle. In China they are sold by the picul, which contains from 9 to 12 bundles. Such as are black or dark-coloured, snap short, or from which the glazing flies off on their being bent, should be rejected. When stowed as dunnage, they are generally allowed to pass free of freight. (*Milburn's Orient. Com.*, &c.) The imports into this country are very considerable. (See *Com. Dict.*)

RA'TTLESNAKE. One of the most deadly of poisonous serpents is so called, on account of the peculiar rattling instrument which it carries at the extremity of the tail, and which is formed of several horny flattened rings, loosely attached together, which move and rattle whenever the animal shakes or alters the position of the tail. These rings increase in number with the age of the animal, and it is asserted it acquires an additional one at each casting of the skin. The generic name of the rattlesnake, *Crotalus* (from the Greek κροταλος, a rattle), relates to the above-mentioned peculiarity. Two species are well distinguished; viz. the *Crotalus horridus* of the United States, and the *Crotalus durissus* of Guiana. The genus is peculiarly American. In common

with the boa, the rattlesnakes have simple transverse plates beneath the body and tail. Their muzzle is hollowed by a little round depression behind each nostril. The habits of the rattlesnake are sluggish; they move slowly, and only bite when provoked, or for the purpose of killing their prey. They feed principally upon birds, rats, squirrels, &c., which it is believed they have the power of fascinating.

RATTLESNAKE ROOT. The root of the *Polygala Senega*, a stimulant said to have proved a serviceable remedy in cases of the bite of the rattlesnake.

RA'VELIN, in Military Works, is a detached work composed of two embankments forming a salient angle. It is raised before the curtain on the counterscarp of the work, serving to cover it and the adjacent flanks from the direct fire of the enemy. When used to cover the approach to a bridge, it is called a *tête du pont*. It is also used in field fortification.

RAY, *Raia*. (Lat. radius, *a ray*.) A genus of cartilaginous Plagiostomous fishes, recognizible by their horizontally flattened and broad disk-shaped body, which is chiefly composed of the immense pectoral fins, the jointed and branched rays of which diverge, like the rays of a fan, and support a broad duplicature of the skin, which is continuous anteriorly with that of the side of the flattened head; whence the name of the genus. The *Raiæ* of Linnæus are now divided into many subgenera, of which the sting ray, eagle ray, electric ray, fire flare, skate, &c. are the respective types.

RAY. In Optics, a beam of light propagated in a straight line from some luminous point. A ray of white light may be divided by refraction into a number of distinct rays of different colours. *See* REFRACTION.

RA'YAH. The designation by the Turkish government of its non-Mohammedan subjects, who pay the capitation tax. Under Bajazet I. the taxable Rayahs in Turkey in Europe were numbered at 1,112,000; under Selim, the late sultan, 1,337,000.

RAZE'E. (Fr.) The term used for any vessel cut down to an inferior class, as a 74 to a frigate, &c. By razeeing, the draught of water is diminished, while the centre of gravity is lowered, and the qualities of the vessel have generally, though not invariably, been improved.

REACH. That portion of the length of a river in which the stream preserves the same direction.

REACTION. A term used in Mechanics to denote the reciprocality of force exerted by two bodies which act mutually on each other; or the general fact, collected from observation, that any two bodies repelling or attracting each other are made to recede or approach with equal momenta. Newton's third law of motion is, that "reaction is always contrary and equal to action, or that the mutual actions of two bodies are always equal, exerted in opposite directions." In the mathematical consideration of mechanics, this principle must be assumed as a necessary axiom or law; and, in fact, as is remarked by Dr. Young (*Nat. Phil.*), there would be something peculiar, and almost inconceivable, in a force which could affect unequally the similar particles of matter; or in the particles themselves, if they could be supposed of such different degrees of mobility as to be equally moveable with respect to one force, and unequally with respect to another. The principle may, therefore, as justly be termed a necessary law as an experimental fact.

REA'DER. In Ecclesiastical matters, one of the five inferior orders in the Romish church. In the church of England, a reader is a deacon appointed to do divine service in churches and chapels of which no one has the cure. There are also readers (priests) attached to various eleemosynary and other foundations.

REAL. *See* MONEY.

REA'LGAR. Red sulphuret of arsenic. It is found native, and is composed of 38 arsenic + 16 sulphur.

RE'ALISM, in Philosophy, has two distinct meanings, according as it is used in contradistinction to *idealism* or to *nominalism*; in the former case relating to the theory of perception, in the second to the theory of abstraction and generalization. For the first, see PERCEPTION, and IDEALISM; for the second, SCHOLASTIC PHILOSOPHY, THOMISTS, SCOTISTS, and NOMINALISTS.

REAL PRESENCE. *See* TRANSUBSTANTIATION.

REAL PROPERTY. Real property is commonly said to consist in "lands, tenements, and hereditaments;" of which terms the last is, in fact, coextensive with the term real property itself, expressing the same thing by the quality which the logicians would term its *difference*, viz. that it descends to the heir wherever held in perfect right: thus distinguished from all other species of full property, which, if possessed in equally absolute right, descend to the executors or administrators of the party. Hereditaments, then, are either corporeal or incorporeal; the first being land and its visible adjuncts recognized by the law as appertaining to it, consisting principally of whatever is fixed thereon; the second, to follow Blackstone's division, are chiefly ten,—advowsons, tithes, rights of common, rights of way, offices, dignities, franchises, corodies (pensions charged on ecclesiastical property, now obsolete), annuities charged on land, and rents reserved out of lands and tenements. The quality of the property which the man may possess in those objects included under the term real (technically called his estate) may vary in *tenure* or in *degree*. *See* FREEHOLD, COPYHOLD, FEE SIMPLE, &c.

REAM. A quantity of paper, consisting generally of twenty quires of twenty-four sheets each; but what is called the printer's ream contains 21½ quires, or 516 sheets. *See* PAPER.

RE'APING. Cutting down corn or pulse with a sickle, hook, or scythe, or by a reaping machine. These operations are more advantageously performed when the corn or pulse is not quite ripe, than when it is thoroughly ripe; because in the latter case the seeds are apt to drop out in the process of handling, turning, and drying.

REAR. The 3d or last division of a fleet, commanded by a rear admiral.

REAR GUARD. That part of an army, a regiment, or battalion, which marches after the main body. *Rear rank* signifies the last rank of a battalion, when drawn up in open order.

REA'SON. (Lat. ratio.) That particular faculty in man of which either the exclusive or the more intense enjoyment distinguishes him from the rest of the animal creation. Like most of the terms in the science of mind, that of reason has been employed in a great variety of significations. Dugald Stewart takes it in its widest sense, and comprises under it all the operations of the intellect upon the materials of knowledge which are furnished in the first instance by sense and perception. Its office is to distinguish the true from the false, right from wrong, and to combine means for the attainment of particular ends. According to this definition, therefore, the province of reason is coextensive with the range of human activity, and it directs itself to the three supreme objects of desire to man,—the good, the beautiful, and the true. Mr. Hume, however, withdraws the discernment of right and wrong, and of the beautiful and its contrary, from the domain of reason; and, on the other hand, also, denies the certainty of the truth which it enunciates, and limits its convincing force merely to a certain weight of probability. Locke's usage of the term, again, partaking as it does of the general looseness of his phraseology, is very different. In one passage reason is declared to be the faculty which finds out the means, and rightly applies them, to discover either the certain agreement or disagreement of two ideas, or their probable connection. But, in another place, it is said to be conversant with certainty alone; while the discovery of what, as probable, enforces a contingent assent or opinion, is ascribed to an especial faculty, which is called the judgment. Bird, on the other hand, confines the latter term to the apprehension of intuitive truth; but agrees so far with Locke as to make it one part of reason, whose other part is reasoning, both demonstrative and moral. On the whole, however, it is clear that in the mind of Locke the terms reasoning and reason were nearly, if not quite, equivalent. But reasoning and deduction are evidently not the source either of the dignity or the authority of the human intellect. The discursive faculty can never establish any other than a conditional truth, which predisposes some anterior and pre-established verity as its basis and verification. If there were not in the human mind something primary, unconditional, and absolute, to which all reasonings might be referred, as to their source and foundation, the discursive process would proceed into infinity, and its conclusions be, as Hume asserts that they are, without any power to enforce assent. But there are unquestionably in the human mind certain necessary and universal principles, which, shining with an intrinsic light of evidence, are themselves above proof, but the authority for all mediate and contingent principles. That which is thus above reasoning is the reason.

In the language of English philosophy, the terms reason and understanding are nearly identical, and are so used by Stewart; but in the critical philosophy of Kant a broad distinction has been drawn between them. Reason is the principle of principles; either speculatively verifies every special principle, or practically determines the proper ends of human action. Approximately, it may be called the sum of what, in Scotch philosophy, has been denominated the laws of man's intellectual constitution. The understanding, on the other hand, is coextensive with the vernacular use of reason. It is that which conceives of sensible objects under certain general notions, which again it compares one with another, or with particular representations of them, or with the objects themselves. It is, therefore, the faculty of reflection and generalization. But the act of comparison is called a judgment; and the understanding, when it enunciates its conceptions, becomes also the faculty of judging. But the truth of a proposition which is not identical, or the enunciation of a primary truth, cannot be immediately certain. To prove it, recourse must be had to other propositions

previously admitted; the understanding, that is, must deduce one judgment from another, and so becomes the discursive faculty, or reasoning. Further, in discovering these mediate truths, and in the regular and methodical disposition of them for the purpose of conclusion, as well as in the selection of means for the accomplishment of its ends, it exhibits itself as a power of adaptation.

By adopting this distinction between reason and understanding much of the difficulty involved in the consideration of instinct will be removed. Instinct is defined to be a natural impulse in animals, by which they are directed to certain actions necessary to the continuation of the individual and of the species, and enabled to perform them unerringly, independent of instruction and experience. To this definition it is usual to add,—without deliberation, and without a view to the end which their actions will effectuate. But these words, while they apply to the instinctive principle in its lowest manifestation, do not belong to it in its highest. That, in some cases, the spontaneity of the animal operates unconsciously, is fully established by experience. The solitary wasp does not itself feed upon flesh, and it cannot know that a larva is to issue from the egg which it is placing in the sand; but yet it deposits in the same hole with it the exact number of green worms that is sufficient for the sustenance of the wasp-worm until, being transformed into a fly, it will be capable of finding food for itself. In other cases, it is impossible to deny the presence of judgment and design, of reasoning and adaptation. It is essential to the nymphæ of the water-moth, or cod-bait, which, by means of the gluten which proceeds from its body, covers itself with pieces of straw or wood, and of gravel or light shells, that it should maintain itself in equilibrium with the water in which it lives. To accomplish this, when its coating is too light it is observed to add a piece of gravel, and a piece of wood when it is too heavy. The former cases may be designated as pure instinct, the latter as instinctive intelligence. Yet, however we may be constrained to assign understanding and intelligence to the operations of the inferior animals, they are manifestly destitute of reason. However exquisite may be the construction of the bee's cell, it is impossible to ascribe to it a knowledge of the mathematical principles of its construction. The bee is born an artist; and prior to, and independently of all instruction and experience, is perfect in its works, and chooses its means with an unerring certainty. But the acts of the rational creature proceed slowly, through diversified and oft-repeated experiments, to realize the principles of the act which are present to its mind; while the means it employs are as various as the individuals, and seldom the best and most appropriate. Again, the acts of the inferior animals are solely subservient to the continuation of the individual, or the propagation of its kind; whereas the works of the rational animal fall short of perfection in many respects, and are rendered still more difficult by a voluntary combination of the beautiful with the simply useful and necessary.

REBATE. (Fr. rabattre.) In Architecture, the groove, recess, or channel, sunk on the edge of any piece of material.

REBEC. A Moorish word, signifying a stringed instrument somewhat similar to the violin, having three strings tuned in fifths, and played with a bow. It was introduced by the Moors into Spain. It appears to have been much used at festive entertainments. Hence Byron, speaking of Seville, says,

Nor here war's clarion, but love's *rebec* sounds.

Milton, in *L'Allegro*, calls it the "jocund rebec."

REBE'LLION, CIVIL. In Scottish Law, by a peculiar fiction, a debtor who disobeys a charge on letters of horning to pay or perform in terms of his obligation is accounted a rebel, by reason of his disobedience to the king's command contained in the writ. The penal consequences formerly attaching to this construction of the law were abolished by 20 G. 2. c. 50.

REBELLION, THE GREAT. The revolt of the Long Parliament against the authority of Charles I., in English History, is commonly so denominated. Nevertheless, as arbitrary and unconstitutional acts were undoubtedly committed on both sides during the struggle which preceded the actual resort to arms, a constitutional lawyer may consider it questionable whether the parliament may be more justly said to have rebelled against the king, or the king against the state. The question is very fairly discussed by Mr. Hallam, in his *Constitutional History of England.* The commencement of the rebellion may be dated from the votes of the two houses concerning the militia (Feb. 1642), by which they endeavoured to seize on the military power of the realm; immediately after which the king left London for the north of England, and hostilities speedily began. (See *Clarendon*, vol. i. p. 2.) In the summer of 1642 the parties first took up arms; the king's standard was set up August 25., and the civil war was ended by the submission of the king to the Scots in April, 1646. The period of the rebellion is, however, extended, in ordinary language, so as to include the Commonwealth or Protectorate, down to the restoration of Charles II. in May, 1660.

RE'BUS. An antiquated species of ingenuity, a great favourite with our ancestors; being an enigmatical representation of a name or thing by using figures for letters, syllables, or parts of words: thus an eye, and a ton or barrel, represent the family name of Eyton; an instance of a rebus borne by way of device, as they very commonly were. (*See* DEVICE.) In heraldry, a coat of arms alluding to the name of the bearer (otherwise called *armes parlantes*) is also called a rebus; *e. g.* three trouts for Troutbeck, three cups for Butler, &c. The term is said to be derived from an annual practice of the priests of Picardy, which consisted in satirizing the people of their vicinity on the recurrence of the Carnival in ingenious squibs, entitled "De *rebus* quæ geruntur."

REBU'TTER. In Law, the fith stage of the pleadings in a suit, or the plaintiff's answer to the defendant's rejoinder. *See* PLEADING.

RECE'PTACLE, in Botany, has four different significations:—1. That part of a flower upon which the carpella are situated; or, in other words, the apex of the peduncle, or summit of the floral branch, of which the carpella are the termination. 2. The axis of the theca of *Trichomanes* and *Hymenophyllum*, among ferns. 3. That part of the ovarium from which the ovula arise, and which is commonly called the placenta. And, 4. That part of the axis of a plant which bears the flowers when it is depressed in its development; so that, instead of being elongated into a rachis, it forms a flattened area, over which the flowers are arranged, as in Compositæ.

RECE'SSION OF THE EQUINOXES. *See* PRECESSION.

RECE'SS OF THE EMPIRE. In History, the name given in judicial language to the decrees of the German diet. They are thought to have been so termed from being pronounced at the time when the diet was about to "recede," or separate. *See* DIET.

RE'CHABITES. A religious order among the ancient Jews, instituted by Jonadab, the son of Rechab, from whom they derived their name. It comprised only the family and posterity of the founder, who was anxious to perpetuate among them the nomadic life; and with this view prescribed to them several rules, the chief of which were,—to abstain from wine, from building houses, and from planting vines. These rules were observed by the Rechabites with great strictness. (See Jer. xxxv. 6.) In recent times, a branch of the body called *tee-totallers* has assumed the name of Rechabites.

RE'CIPE. The symbol ℞ at the head of a medical prescription generally means *recipe*, or "take." Dr. Paris says this character is a relic of the astrological symbol of Jupiter, a planet under the ascendency of which herbs were often collected or prepared. (*Pharmacologia.*)

RECI'PROCAL. In Arithmetic, the quotient resulting from the division of unity by any number. Thus, $\frac{1}{2}$ is the reciprocal of 2; and, conversely, 2 is the reciprocal of $\frac{1}{2}$.

RECI'PROCAL FIGURES, in Geometry, are two figures of the same kind (triangles, parallelograms, prisms, pyramids, &c.), so related that two sides of the one form the extremes of an analogy of which the *means* are the two corresponding sides of the other.

RECI'PROCAL PROPORTION, is when, of four terms taken in order, the first has to the second the same ratio which the fourth has to the third; or when the first has to the second the same ratio which the reciprocal of the third has to the reciprocal of the fourth. In works of arithmetic the case which give rise to this class of relations is called Inverse Proportion, or the Rule of Three Inverse.

RE'CITATIVE. (Lat. recitare, *to recite.*) In Music, a species of singing differing but little from ordinary speaking. It is used in operas, &c., to express some action or passion, or to relate a story, or reveal a secret or design; and though written in true time, the performer may alter the parts of the measure as he thinks most suitable to produce certain effects, those that accompany him being dependent on his pleasure.

RE'CKONING. In Navigation, the estimated place of a ship, calculated from the rate as determined by the log, and the course as determined by the compass, the place from which the vessel started being known. An elegant and ready method for solving this problem has been recently given by Professor Gill of New York, in the first number of his *Mathematical Miscellany*, much more accurate than the method usually given by writers on navigation. (*See* NAVIGATION.) *Dead reckoning* means the same as *reckoning*, due allowance being made for drift, lee-way, currents, &c.

RECLINA'TION (Lat. reclino, *I repose*), in Dialling, is the angle which the plane of the dial makes with a vertical plane which it intersects in a horizontal line.

RECLU'SE. The common title of a class of religious persons in Roman Catholic countries. *See* INCLUSI.

RECO'GNIZANCE. In Law, an acknowledgment of

a debt upon record. By a fiction of law, the obligation which a party enters into before a court of record or magistrate duly authorized, with condition to do some particular act, — as to appear at the assizes, keep the peace, &c., — is in the form of a recognizance; the party acknowledging himself to be indebted to the king, the plaintiff, &c., with condition that the obligation shall be void on performance of the thing stipulated.

RECOI'L, in Artillery, is the rebound or resilience of a piece of ordnance when discharged. This has been employed for the determination of the explosive force of gunpowder; but the method does not appear to be susceptible of much accuracy. *See* GUNNERY.

RE'COLLETS, or RE'COLLECTS. Monks of the order of St. Frances under a reformed rule. The first separation from the original body seems to have taken place towards the end of the 14th century, when some religious persons, desirous of returning to stricter discipline, assumed the title of Brothers of the Observance. From these originated the Recollects (living in a state of *recollection*, or reclusion), first established in Spain by the Count de Belalcazar, about 1484, and afterwards introduced into Italy. After much opposition, they acquired the possession of great wealth and court favour in France, during the 16th and 17th centuries.

RECORD. Literally an authentic account of any fact or transaction in writing, contained in rolls of parchment, wood, or any other durable substance, and preserved in a court of record. *See* ARCHIVES.

RECORD. In Law, the authentic testimony in writing, contained in rolls of parchment, of the judgment of a superior court, and of the other proceedings in a case. Records are said to be of three kinds: — judicial records; ministerial records on oath, being offices or inquisitions found; records made by conveyance or consent, as fines, recoveries, or deeds enrolled. (*See* COURT.) Trial by record is used where a matter of record is pleaded in any action, as a fine, judgment, &c.; and the opposite party pleads "nul tiel record," that there is no such record existing. On this issue is joined, which can be tried only by inspection of the record

RECORDA'RI FA'CIAS LOQUE'LAM. In Law, a writ to remove proceedings out of an inferior court to the King's Bench or Common Pleas. It is directed to the sheriff, commanding him to make a record of the plaint and other proceedings, and then to send up the cause. It is the common mode by which an action of replevin is transferred from the sheriff's to the superior courts.

RECO'RDER. The chief judicial officer of a borough or city, exercising within it in criminal matters the jurisdiction of a court of record; whence his title is derived. This jurisdiction is now made uniform in extent throughout all boroughs, and is rendered equal to that of the quarter sessions of a county. Recorders were formerly chosen without restriction by the corporations with which they were connected; but by the existing municipal system the appointment is vested in the crown, and the selection is confined to barristers of five years' standing.

RECORDER. The name of a musical instrument somewhat resembling the flageolet, formerly in use in this country. It had a peculiarly pleasing tone; hence Milton speaks of

> ——— The Dorian mood
> Of flutes and soft recorders.

The etymology of the term is involved in great obscurity.

RECO'VERY, or COMMON RECOVERY. In Law (*see* FINE), a mode of assurance in the form of a fictitious action, by means of which conveyances were made by various tenants possessed of limited rights in real property (by tenants in tail more particularly). The effect of a common recovery duly suffered was to raise an absolute bar, not only of all estates tail, but of all estates in remainder and reversion expectant on such estates tail; and to give the recoverer a fee-simple absolute. A common recovery, however, did not bar a springing use, or an executory devise. A common recovery also avoided all charges, leases, and incumbrances made by those in reversion or remainder. By 3 & 4 W. 4. c. 74. common recoveries are abolished, and a new mode of conveyance for the use of tenant in tail substituted for them. *See* ESTATE TAIL.

RE'CTANGLE. In Geometry, a right-angled parallelogram. When the adjacent sides are equal, it becomes a *square*. The area of a rectangle is numerically expressed by the product of the two numbers which express the lengths of its adjacent sides, and hence the term rectangle is sometimes, but incorrectly, used for product.

RECTIFICA'TION. In Geometry, the determination of a straight line, whose length is equal to a portion of a curve. It is effected by the integral calculus.

If the curve be entirely in one plane, the length of the arc is $\int\sqrt{dy^2+dx^2}$; or if it be a curve of double curvature, its length is $\int\sqrt{dx^2+dy^2+dz^2}$. In the former case, the equation of the curve being single will give a value of dy or dx, as may be found most convenient; and this being substituted in the above formula, and the expression integrated between the specified limits, the actual length is obtained. In the second case, the equations upon two of the planes of projection being given, the values of dy and dz can be obtained in terms of du (u being another variable), and the values of y and z in terms of u; then these substitutions being made, the process is the same as before. *See* INTEGRAL CALCULUS.

It will, however, very rarely happen that the rectification can be obtained in finite terms, as the substitutions generally introduce radical expressions into the differential, which are hardly ever so connected with the rational parts as to be susceptible of a finite integral; and hence it has been an object with mathematicians to transform the expressions into others, the successive terms of which are so related as to diminish at a very rapid rate. In this case, the approximation to the value of the arc is rendered comparatively easy. The first curve which was rectified was the semicubical parabola; and the merit belongs to a Mr. Neale, whose rectification was published in 1657. Two years later the same curve was rectified by Van Heureat, in Holland.

RECTIFICATION. A Chemical term, generally implying a second or more frequently repeated distillation; thus, "rectified spirit of wine," means spirit which has been redistilled, and by which it is to a great extent freed from water, or rendered stronger.

RECTILI'NEAL, or RECTILI'NEAR FIGURE, in Geometry, is a figure bounded by straight lines.

RE'CTOR (Lat. rector ecclesiæ, *ruler of the church*), is a person who hath the charge and care of a parish church. The other rector is a layman, or a college or corporate body (*see* art. TITHES). He is bound to provide a vicar to serve the church in his place, and to allow the small tithes, or a sufficient stipend, for his maintenance. The term *rector* is also employed in Scotland to designate the head master of a public school or academy.

RECTRI'CES. (Lat. rectrix, *a guide*.) The name of the tail feathers of a bird, which, like a rudder, direct its flight.

RE'CTUM. (Lat. *straight*.) The last portion of the large intestines; so named from an erroneous notion of the old anatomists that it was straight.

RECU'MBENT. (Lat. recumbo, *I lie down*.) In Zoology, when a part is leaning or reposing upon any thing.

RECU'RRENT NERVES. Two branches of nerves from the *par vagum*, in the cavity of the thorax, are so called; they are distributed to the muscles of the larynx and pharynx.

RECU'RRING DECIMALS, or CIRCULATING DECIMALS, in Arithmetic, are decimals which arise from the expansion of a fraction whose denominator includes one or more prime numbers, as factors, different from 2 or 5, and not included in the numerator. In this case the same figures are continually repeated in the same order. Thus, $\frac{2}{11} = \cdot181818$, &c.; $\frac{1}{7} = \cdot1428571428571$, &c., *ad infinitum*. Their value can always be found by taking one of the periods for a numerator, and as many nines for the denominator as there are figures in the period, and reducing the resulting fraction to its lowest terms. Thus, $\frac{142857}{999999}$ being so reduced, is found equal to $\frac{1}{7}$.

Recurring decimals were first noticed by Dr. Wallis; but their properties have not been extensively investigated.

RECU'RRING SERIES. In Algebra, a series in which the coefficients of the successive powers of x are formed from a certain number of the preceding coefficients according to some invariable law. Thus $a + (a+1)x + (2a+2)x^2 + (3a+3)x^3 + (5a+5)x^2 + \ldots$ is a recurring series, the coefficient of each term being the sum of the coefficients of the two preceding terms. The value of the terms of such a series can always be exhibited in a finite form. (See Euler, *Introductio in Analysin Infinitorum; Bourdon's Algebra*, &c.)

RECU'SANTS. In English History, a term applied to those who refused to acknowledge the king's supremacy as head of the church, chiefly Papists.

RED. One of the primary colours. *See* CHROMATICS.

RE'DAN. In Fortification, a kind of rampart placed in advance of the principal works to defend the least protected parts. The redan usually consists of a rampart of earth; and it is the simplest kind of field fortification. *See* FORTIFICATION.

RED BOOK. The name given to a book containing the names of all persons in the service of the state. The *Red Book of the Exchequer* is an ancient record, in which are registered the names of all those that held lands *per baroniam* in the time of Henry II.

RE'DDLE. A soft argillaceous mineral deeply tinged with red by oxide of iron. The best specimens, used as drawing chalk, are brought from Germany.

REDE'MPTORISTS. A religious order founded in Naples by Liguori in 1732, and revived in Austria in 1820. They are bound by the usual monastic vows, and devote themselves to the education of youth and the propagation of Catholicism. They style themselves members of the order of the Holy Redeemer (il Santo Redemptore), whence their name; but they are also often called *Liguorists*, from the name of their founder.

RED LEAD. An oxide intermediate between the protoxide and peroxide of lead. *See* LEAD and MINIUM.

RED MARL. New red sandstone. *See* GEOLOGY.

RED PRECIPITATE. The peroxide of mercury, obtained by the decomposition of nitrate of mercury by heat. *See* MERCURY.

REDOU'BT. In Fortification, a term applied to nearly every kind of work intended to fortify military positions; as also to works constructed within others to prolong their defence; or to detached works used to secure some piece of ground which would be useful to the besiegers, and thereby create delay in offensive operations.

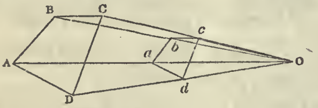
REDU'CING SCALE. A scale used by surveyors for turning links into roods and acres by inspection.

REDU'CTION. The process of converting a metallic oxide into metal by expelling its oxygen. In some cases it is effected simply by heat, but generally by the joint action of heat and some deoxidizing agent: upon the large scale, charcoal is almost always resorted to.

REDUCTION. In Arithmetic, the changing of quantities from one denomination to another.

REDUCTION OF FIGURES, in Practical Geometry, consists in describing figures similar to the given ones, but of different (generally smaller) dimensions. The pentagraph and the proportional compasses are the readiest and most accurate methods of performing these reductions; but in the absence of these, many different methods are taught in works of practical geometry. The simplest is here annexed.

Let A B C D be the figure to be reduced, and *a b* be



the line which is homologous to A B. At a convenient place on the paper draw *a b*, parallel to A B, and equal to the reduced line. Draw A *a*, B *b*, meeting in O, and from O draw lines to all the other angles of the figure; then draw *b c* parallel to B C, *a d* parallel to A D, &c.; and join the last two points. Then *a b c d* is the reduced figure sought.

If the proposed figure be curvilinear, inscribe any polygon within it, and draw the similar polygon as above directed; then trace the curve through the angles of the polygon.

REDU'NDANT HYPERBOLA. A line of the third order, having three pairs of asymptotic branches. Its properties may be seen in *Newton's Enumeratio*.

REEF, in Navigation, signifies to diminish the surface of the sails on the increasing of the wind. Sails attached to yards are reefed at the head. Strong horizontal bands of canvass, from three to six feet apart, extend across the sails; these are called *reef bands;* and there are usually four in each topsail, and two in the foresail and mainsail. The reef band is commonly pierced with two holes in each cloth (or breadth of canvass) in the sail; through each hole are drawn two *reef points*, — short pieces of flat rope, each having an eye in one end, and hung one before and the other abaft the sail, each passing through the eye in the end of the other. The sail being lowered and trimmed to the wind so as to shake; the extremities of the reef band are drawn up towards the *yard arm* by the ropes called *reef tackles;* the men then going out upon the yard, which they lean over while their feet are supported by the *foot ropes*, gather up the loose canvass of the sail till they reach the reef band, which they keep extended tight along the yard until the *earings* are *passed* or secured, the weather earing being passed first; they then tie the two reef points of each pair together over the yard, and the sail is reefed, the surface having been thus diminished by the depth of one reef. Gaff sails are reefed at the foot. The sail being lowered enough to slack the canvass, the earing which is on the after leech is brought or hove down to the boom end by a strong rope called a *reef pendant;* the men then standing wherever they can reach the foot of the sail, tie the points under it. When the yard is not lowered, as in reefing the courses, the sail is partly clued up for reefing.

REEF, or CORAL REEF, is also applied to a chain of rocks in various parts of the ocean lying near the surface. *See* GEOLOGY.

REEL. A lively dance peculiar to Scotland, generally written in common time of four crotchets in a bar, but sometimes in gig time of six quavers.

REEL. An angler's implement attached to the but of the rod, for the purpose of winding in the line when a fish is hooked. The barrel of the reel should be of sufficient diameter to wind in quickly, as a fish is often lost by not being able to bring him rapidly within reach of the landing net; especially where, as in fly-fishing, a great length of line has been thrown out.

RE-E'NTER. In Engraving, a word which denotes the passing of the graver into those incisions of the plate, so as to deepen them, where the aquafortis has not bitten in sufficiently.

RE-E'NTERING ANGLE. In Fortification, the angle of a work whose point turns inwards towards the defended place.

REEVE. (Ang. Sax. gerefa, *an officer or governor.*) A word of a very general application, entering into the composition of some titles yet in use. Hence *sheriff*, *i. e.* shire-reeve, the governor of a shire or county; borough-reeve, port-reeve, &c.

REEVE. The Sea term for putting a rope through a block, or any hole through which it is intended to run.

REFE'CTION. (Lat. reficio, *I restore.*) In the language of Ecclesiastical communities, a spare meal, sufficient only to maintain life; whence the hall in convents where meals are taken is termed *refectory.*

REFE'CTORY. (Lat. refectorium.) In Architecture, an apartment wherein meals are taken.

REFERE'NDARIES. In the early monarchies of Europe after the fifth century, public officers charged with the duty of procuring, executing, and despatching diplomas and charters. The office of great referendary, in the French monarchy, became merged in that of chancellor.

REFLE'CTING CIRCLE. An astronomical instrument for the measurement of angles by reflection. (*See* SEXTANT.) The term is also applied to a surveying instrument, invented by Sir Howard Douglas, which combines the advantages of the Hadley's quadrant and the protractor. The object of it is to protract, or lay down on the plan, the angles measured with the instrument from the instrument itself, without any intermediate step, or even a register of their values. The advantage of such an instrument must be obvious in military surveys, where expedition is important, while accuracy is thereby far more efficiently insured than by the old and more tedious process. It is also advantageously used in forming general sketches of a country.

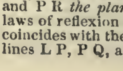
RE'FLEX. (Lat. reflecto, *I bend back.*) In Painting, the illumination of one body, or a part of it, by light reflected from another body. The foundation of the law of *reflexes* depends upon the knowledge that every body in light reflects that light, to a certain degree, in the same way that flame does. The stronger, therefore, the light on the body, the stronger will be the *reflex*, distances being equal. Again, the more directly the light falls on a body, the more influence it will have in imparting a reflex.

REFLE'XION, in Mechanics, denotes the rebound or regressive motion of a body from the surface of another body against which it impinges. In Natural Philosophy, the term is applied to the analogous motions of light, heat, and sound, when turned from their course by an opposing surface. The laws of the reflexion of light form the branch of science called *catoptrics;* those of the reflexion of sound are sometimes called *cataphonics*. *See* SOUND.

The simplest view which can be taken of the mechanical action whereby reflexion is produced, is to assimilate it to that which takes place when an elastic body impinges on another body which it cannot move out of its place. If light, heat, and sound are propagated by the pulses of an elastic medium, the same theory will apply to them; and it is to be remarked, that in all cases of reflexion the change of motion which takes place follows precisely the same laws as that which is produced by the impact of two elastic bodies.

Reflexion of Light. — When we consider only the *direction* of the rays of light after being reflected from a polished surface, and leave its *quantity* or *intensity* out of view, the laws of reflexion are extremely simple. Suppose A B (fig. 1.) to be a smooth polished surface, or mirror, and a ray of light proceeding in the direction L P to impinge on the surface at P, and to be reflected from it in the direction P R. Through the point P draw P Q a normal or perpendicular to the surface; then, adhering to the definitions adopted by most writers on optics, the angle L P Q is called *the angle of incidence*, Q P R *the angle of reflexion*, the plane in which are the two straight lines L P and P Q is called *the plane of incidence*, and the plane determined by Q P and P R *the plane of reflexion*. Now the two general laws of reflexion are these: — 1st, The plane of reflexion coincides with the plane of incidence; or the three straight lines L P, P Q, and P R, are in one plane. 2d, The angle

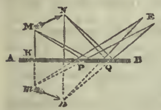
(1.)



of reflexion is equal to the angle of incidence, and on the opposite side of the normal. These laws hold true, whatever be the nature of the reflecting surface, or the origin of the light which falls on it. Experience offers no exception to them whatever; and all the phenomena of reflexion from mirrors or polished surfaces, whether plane or having any regular curvature, are readily deduced from them as simple geometrical consequences.

Reflexion from Plane Mirrors.—To determine the path of the reflected rays, and the formation of images by plane mirrors, suppose M N (fig. 2.) to be an object placed before the plane reflecting surface A B, and the eye to be situated at E. The rays of light which proceed from the point M, and are reflected to the eye at E, will impinge on the mirror at P, and appear to come from a point *m*, which, in respect of the plane A B, is symmetrical with M; that is to say, placed in the straight line which is drawn from M perpendicular to the surface, and at the same distance from A B on the opposite side. For let M K be the perpendicular, and let it be continued till it meet the prolongation of E P in *m*; then, from the equality of the angles of incidence and reflexion, the angles M P K and E P B (which are the complements of those angles) are equal; hence M P K = K P *m*; and the two right-angled triangles K P M and K P *m*, having also a common side, are every way equal; whence K *m* = K M. In like manner, the rays which issue from N, and are reflected to E, will appear to proceed from a point *n* symmetrical with N; and as the same thing is evidently true with respect to every other point of the object, a perfect image *m n* of the object will be formed on the opposite side of the mirror, and at the same distance. It will be observed that the image is not, properly speaking, reversed, like writing looked at through the opposite side of the paper: the spectator sees the same side of the object as if he stood in front of the mirror, and viewed the object directly; but, in the reflected image, right takes the place of left, and left of right.

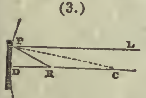
(2.)



Reflexion from Curve Surfaces. — In order to apply the two general laws of reflexion to the determination of the direction of a ray reflected from a curve surface, it is assumed that the reflexion takes place at each point of the surface in the same manner as it would from a plane touching the curve surface at that point, and the problem therefore becomes that of determining the direction of the normal at the given point; for, when the direction of the incident ray, and of the normal at the point of incidence, are both known, the plane of the reflected ray, and the position of the ray in that plane, are both given. The mirror may be concave or convex; and the incident rays may be parallel or divergent.

Let D (fig. 3.) be the centre of a concave mirror, D C its axis, C the centre of curvature at D; and assume the semidiameter of the mirror D P to be small in comparison of its radius of curvature C D. Now suppose a ray of light L P, parallel to the axis, to fall on the mirror at P; then, if we draw P C, and make the angle C P R = C P L or P C D, P R will be the direction of the reflected ray; for, by the nature of curvature, C P is a normal to the surface, the arc D P being small. But, on the hypothesis of D P being small, we have also R P = R D; and by reason of the equal angles R P C and R C P, R P = R C, therefore R D = R C; or R is a given point, and, consequently, all the rays which fall on the mirror parallel to C D are reflected into the same point R. From this property the point R, which bisects the radius C D, is called *the principal focus* of the mirror, or *the focus of parallel rays*. *See* Focus.

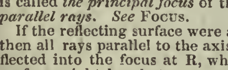
(3.)



If the reflecting surface were a portion of a paraboloid, then all rays parallel to the axis would be accurately reflected into the focus at R, whatever the extent of the surface might be; but, on account of the practical difficulty of grinding and polishing curve surfaces of any other form than the spherical, the concave and convex mirrors required for optical purposes are always spherical.

Suppose, next, the rays to diverge from a point in the axis of the mirror. Let L (fig. 4.) be the luminous point, C the centre of curvature, and P R the reflected ray. To find the point R, let I = L P C = R P C; and let R, C, L denote respectively the acute angles at the points indicated by these letters. We shall then have, obviously, R − I = C, and I + L = C; whence L + R = 2 C. Now, since D P is supposed to be an arc of a small number of degrees, D P may be regarded as a straight line perpendicular to L D; and since the angles R, C, L are also small, we may substitute for the arcs to which they respectively correspond their trigonometrical tangents, namely, $\frac{PD}{DR}$, $\frac{PD}{DC}$, $\frac{PD}{DL}$. Hence, if we assume D L = p, D R = q, D C = r, the radius of curvature, the above equation R + L = 2 C will become

(4.)



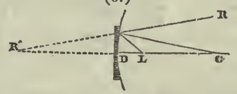
$$\frac{1}{p} + \frac{1}{q} = \frac{2}{r},$$

which gives the relation between p and q, r being a constant quantity for the same mirror. If, therefore, L be a given point, then p has a given value, and q is also determined; so that all rays diverging from the point L, and falling on the mirror, are reflected into the point R. As the two quantities p and q enter symmetrically into the equation, each being expressed in terms of the other by the same formula, the points R and L are interchangeable; that is, if R be taken as the radiating point, then L is the focus of the reflected rays. Hence L and R are called *conjugate points*, or *conjugate foci*.

Since the reciprocals of p and q always make up the same sum, when one of those quantities increases the other diminishes, and *vice versâ*. If, therefore, L approaches towards C, R will also approach towards C (the origin being supposed at D), and they will ultimately coincide at that point, so that a ray issuing from C would be reflected back on itself. If L recedes from C, then R recedes from C, or approaches D. Suppose L to be at an infinite distance; in this case $1 \div p = 0$, and the equation gives $q = \frac{1}{2} r$, or D R = $\frac{1}{2}$ D C; so that R becomes the *principal focus*, as it evidently ought; for when L is at an infinite distance, the rays L P are parallel to the axis.

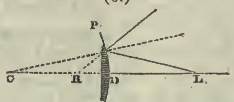
It is evident from the above equation that so long as p and q have the same sign, that is, so long as L and R are on the same side of the mirror, each of those quantities must be greater than $\frac{1}{2} r$. Suppose the radiating point L to be placed between D and C (fig. 5.), and let D L or p become less than $\frac{1}{2} r$. In this case, q must become negative; that is to say, the rays which emanate from L must become divergent after reflexion, and have the same direction as if they diverged from a point R′ on the opposite side of the mirror, and of which the distance q from D is determined by the equation $\frac{1}{p} - \frac{1}{q} = \frac{2}{r}$. This point R′ is called the *virtual focus* of the reflected rays.

(5.)



The same construction and equation (with the proper changes of sign) apply equally to convex and concave mirrors. Let L (fig. 6.) be the luminous point, from which diverging rays fall on the convex mirror P D, of which C is the centre of curvature. Denoting, as before, D L, D R, and D C, by p, q, and r respectively, and assuming the constant r to be positive, then, by exactly the same reasoning as above, we shall find the equation

(6.)

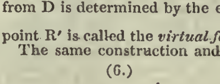


$$\frac{1}{q} - \frac{1}{p} = \frac{2}{r}.$$

In this case, p and q increase or decrease simultaneously; and if we suppose p to increase to infinity, or the incident rays to become parallel, then we have again $q = \frac{1}{2} r$; so that, for parallel rays, the conjugate focus is at the middle of the distance between D and C. When the mirror is convex, the conjugate focus is always the virtual focus.

From what has now been shown, it is easy to see in what manner images are formed by concave or convex mirrors. Let M N (fig. 7.) be an object placed before a concave mirror A B, beyond its centre of curvature C. On tracing the path of the rays M A, M D, M B, after reflexion, they will all be found to meet in the point *m* and those which proceed from N will in like manner be found to meet in *n*; whence rays diverging from every point of the object between M and N will meet, after reflexion, in a point situated between *m* and *n*; and in this manner an inverted image *m n* of the object will be formed. The magnitude of the image is to that of the object as *D m* to D M, or as the distance of the image from the mirror is to the distance of the object from the mirror; and the image will be more brilliant in proportion as the rays of light coming from the object are collected within a smaller space. If the object were

(7.)



placed at $m\,n$, then an enlarged image would be formed at M N. It is on this principle that reflecting telescopes and microscopes are constructed. *See* TELESCOPE, MICROSCOPE.

Intensity of reflected Light. — It has now been shown that the path of the reflected light can be determined in all cases with geometrical precision, when the form of the reflecting surface is known; but the case is very different when the question is to determine the quantity or proportion of the light which is thrown into a different direction by an opposing surface. The following laws, however, have been established by experiment: — 1st, The quantity of light regularly reflected increases with the angle of incidence, but does not vanish entirely when that angle becomes 0. 2d, It depends both on the nature of the medium through which the light is passing when it falls on the reflecting surface, and on that of the substance on which it falls. 3d, Bodies of different natures, placed in the same circumstances, reflect very different proportions of the incident light.

On this subject a great number of experiments were made by Bouguer, and more recently by Arago, Fresnel, Mr. Potter, and others. The following numerical relations are given by Bouguer: — When a beam of light, the intensity of which is represented by 1000, falls upon water so as to make an angle of 0° 30′ with the surface, the intensity of the reflected light is represented by 721; at an angle of 15° with the surface, by 211; at an angle of 30°, by 65; and at an angle from 60° to 90°, by 18. Of 1000 rays falling upon a surface of glass, and making an angle of 5° with the surface, 543 are reflected; 300 when the angle is 15°; 112 when 30°; 25 when 60°, or above. Of 1000 rays falling on a polished surface of black marble, 600 are reflected when the angle with the surface is 3° 15′; 156 when 15°; 51 when 30°; 23 when 60° and upwards. Mercury and metallic mirrors give a less rapid diminution. Of 1000 incident rays, 700 are reflected when the angle with the surface is very small; and about 600, or more than half, when the angle approaches to 90°, or the incident ray is nearly perpendicular to the surface. (*Traité d'Optique.* See also the *Edinburgh Journal of Science* for 1830 and 1832.)

In order to produce reflexion in a greater or less degree, the only indispensable condition is, that light pass from one medium to another having a different refractive power. In passing through a perfectly homogeneous medium, no reflexion takes place; but whenever there is a change of medium (and this change may occur in the same substance by an inequality of density in the different parts, or a different arrangement of the particles), more or less reflexion takes place at the surface which separates the two media. Thus, in passing through the atmosphere, the solar light undergoes an infinite number of partial reflexions before it arrives at the earth, as every successive thin stratum of air, by reason of its increasing density, forms, as it were, a different medium. *See* REFRACTION, ASTRONOMICAL.

If any surfaces could be formed of so perfect a polish as to reflect the whole of the incident light, the eye would be unable to distinguish them; and, unless by coming in actual contact with them, we should have no reason to suspect their existence. Bodies are only visible in consequence of rays irregularly reflected from their surfaces meeting the eye; for rays which are regularly reflected only show the luminous points from which they emanate, and not the surfaces on which they fall. If the lunar surface were as perfectly polished as a globule of pure mercury, the moon would present to us only a reflected image of the sun. *See* LIGHT, OPTICS.

REFORM ACT. In Politics. *See* PARLIAMENT.

REFORMA'TION. An important era in political and ecclesiastical history, when the doctrines and usages of the Romish church, then dominant throughout the western states of Christendom, were first successfully called in question. This event is commonly dated from the year 1517, when Luther began to oppose the pope and condemned the sale of indulgences. Mosheim assigns to it the date 1520, when Luther was excommunicated.

Prior to the Reformation, the pope claimed of divine right, and exercised, absolute authority over the whole Christian church, with the exception of those states and provinces in which the Eastern or Greek church was established. Not only was his authority regarded as supreme on subjects of doctrine and discipline, but his decisions were considered as infallible; and whoever ventured to question or gainsay them was treated as a heretic, and was liable to such canonical censures and temporal penalties as the canon law determined. Of course, the exercise of private judgment in religious and ecclesiastical matters, or the right of the people to peruse the sacred volume, was peremptorily denied. Nothing, therefore, could be more absolute than was the government of the Christian church under the see of Rome. His holiness, also, laid claim to supremacy even in temporal things throughout the wide range of his religious authority; though the exercise of this supremacy was not always quietly submitted to; nay, was sometimes resisted with success. He regarded all parts of the world not inhabited by Christians as uninhabited, and gave full power to those Christians who might occupy them to make war on the inhabitants; and the countries, if conquered, were parcelled out according to his sovereign pleasure. But while the absolutism claimed by the Roman pontiff was calculated to arouse jealousy and opposition, which, indeed, it did, in some degree, in different places and at various times, these feelings were greatly increased by several other causes: such as the immoral lives of the clergy; the facilities by which their immoralities were pardoned; the exorbitant wealth of the church; the great personal immunities of ecclesiastics, and their encroachments on the jurisdiction of the laity. These and similar circumstances, which the invention of the art of printing and the revival of learning had tended more thoroughly and widely to disclose, gradually prepared the public mind for that reformation of religion of which in this article we intend briefly to give an account.

Without minutely mentioning the frequent, but comparatively feeble opposition, to which the absolutism in the government of the church had, in various periods, given rise, it may suffice here to confine ourselves to an account of that course of opposition, in the 16th century, which terminated in the Reformation.

According to the doctrine of the Romish church, all the good works of the saints, over and above those necessary for their own justification, are deposited, together with the infinite merits of Jesus Christ, in one inexhaustible treasury. The keys of this treasury were committed to St. Peter, and his successors the popes, who may open it at pleasure, and by transferring a portion of this superabundant merit to any particular person for a sum of money, may convey to him either the pardon of his own sins, or a release for any one in whose happiness he is interested from the pains of purgatory. Hence the origin (which took place in the 11th century) of the sale of *indulgences*. Pope Leo X., under the pretence of raising contributions towards building the church of St. Peter at Rome, granted, in 1517, the right of promulgating those indulgences in Germany, together with a share in the profits arising from the sale of them, to the archbishop of Magdeburg, who, as his chief agent for retailing them in Saxony, employed Tetzel, a Dominican friar, of dissolute morals, but of great activity and energy of character. Tetzel, assisted by the monks of his order, executed the commission with great zeal, but with little discretion or decency; and, by disposing of them at a very low price, carried on for some time an extensive and lucrative traffic among the credulous and ignorant. The princes and nobles were irritated at seeing their vassals drained of their wealth to replenish the treasury of a profuse pontiff. Men of piety regretted equally the corruptions of the church and the delusions of the people. Even the most unthinking were shocked at the scandalous behaviour of Tetzel and his associates. But it was reserved to Martin Luther, formerly a monk of the Augustine order, and at that time professor of theology at Wittenberg, effectually to expose the artifices of those who sold, and the simplicity of those who bought indulgences, and to shake the foundations of the papal see itself. What were the motives which first induced this distinguished person to oppose this traffic cannot now be ascertained. The traffic was not a novelty, as it had been practised throughout Christendom for several centuries. Some writers have imagined, though with what justice is not evident, that his opposition was founded in jealousy, because this gainful trade had not been conferred on the Augustinians, to whom he belonged, but on the Dominicans, a rival order. But, whatever were his motives, his opposition at first was confined simply to the sale of indulgences. His memorable theses, ninety-five in number, against this practice were affixed to the doors of the cathedral of Wittenberg, 31st October, 1517; while from the pulpit he inveighed bitterly against the irregularities and vices of the monks who published indulgences, as well as against the abuse itself. The sentiments contained in his theses he proposed not as points fully established, or of undoubted certainty, but merely as subjects of inquiry and disputation: he appointed a day on which the learned were invited to impugn them, either in person or by writing; and to the whole he subjoined solemn protestations of his high respect for the apostolic see, and of his implicit obedience to its authority. No opponent appeared at the time prefixed. Meanwhile the theses spread over Germany with astonishing rapidity; they were every where read with the greatest avidity; and all admired the boldness of the man who had ventured to attack the plenitude of papal power. Meanwhile Tetzel, in opposition to Luther, published counter-theses at Frankfort on the Oder; Eckius, a celebrated divine of Augsburg, endeavoured to refute Luther's notions; and Prierias, a Dominican friar, master of the sacred palace and inquisitor-general, wrote against him with uncompromising virulence. But this

opposition was of little or no avail. Luther supported his views by arguments founded on reason or derived from scripture, and his cause was found daily to gain strength.

Leo, naturally fond of ease, and occupied in the pursuits of pleasure and ambition, paid little or no attention to the dispute that was thus raging in Germany, and at at first despised it as a mere monkish squabble. But the tidings of Luther's rapid success, and the clamours of the ecclesiastics for aid and vengeance, at length roused him from his apathy, and induced him to take prompt steps to put a stop to the spread of heresy. On the 21st Aug. 1518, he summoned Luther to appear at Rome within sixty days, before the auditor of the chamber and the inquisitor-general Prierias, who had written against him, whom he empowered jointly to examine his doctrines and to decide concerning them. This was evidently an unjust tribunal by which the decision was to be made; and through the influence of Frederick the elector of Saxony, who was favourable to the new doctrines, and of others, and by a submissive letter written to the pope by Luther himself, his holiness agreed to refer the hearing and determining of the cause to his legate in Germany, Cardinal Cajetan, a Dominican, eminent for scholastic learning.

The reformer accordingly appeared before Cajetan, who, after some discussion, commanded him to retract his opinions; but Luther, with that intrepidity of mind which was his grand characteristic, declared that he could not, with a safe conscience, renounce opinions which he believed to be true, nor should any consideration induce him to do what would be so base in itself, and so offensive to God. The result was, that Luther, who, with his friends, suspected that even the imperial safe-conduct would not be able to protect him from the legate's power and resentment, was induced to withdraw secretly from Augsburg and return to Wittenberg; previously to which, however, he prepared a solemn appeal from the pope ill informed at that time concerning his cause, to the pope when he should be better able to judge respecting it. (*Secken*, *Comment.* lib. i. p. 14.; *Lutheri Opera*, i. p. 160.) But so impatient were Luther's enemies at Rome that even before the sixty days had expired, he was there condemned as a heretic; and Leo, in several of the briefs and letters, had stigmatized him as a child of iniquity, and as given up to a reprobate mind. But Luther, convinced that his views were agreeable both to scripture and reason, was not to be deterred from teaching and promulgating his opinions both from the pulpit and through the press; and as every step taken by the court of Rome against him convinced him that Leo would soon proceed to the most violent measures, he had recourse to the only expedient in his power in order to prevent the effect of the papal censures. He appealed to a general council, which he affirmed to be the representative of the Catholic church, and superior in power to the pope, who, being a fallible man, might err, as St. Peter, the most perfect of all his predecessors, had erred. As opposition against him increased, and as the controversy advanced, Luther's views began to expand; and in his disputation with Eckius, he went so far as to question the supremacy of the pope over the church, as well as the doctrines of purgatory, auricular confession, and absolution; and he about the same time published several treatises, in which he more openly expressed his dissent. Luther may now be said to have embraced the fundamental tenet which now characterizes all sects of Protestants, and which was subversive of the slavish obedience in points of doctrine and discipline which had hitherto been paid to the holy see; namely, that scripture is the only rule of faith and manners, and that this rule is to be interpreted by the exercise of private judgment. A step was at this period (June, 1520) taken by the court of Rome fatal to the object which it had in view. The pope issued a bull condemning, as heretical and offensive to pious ears, forty-one propositions extracted out of Luther's works; all persons were forbidden to read his works on pain of excommunication; those who possessed a copy of them were commanded to commit it to the flames; and he himself, if he did not within sixty days publicly recant his errors and burn his works, pronounced a heretic, excommunicated, and delivered unto Satan; and all secular princes required, under pain of incurring the same censure, to seize his person, that he might be punished as his crimes deserved.

This sentence, while it did not disconcert or intimidate Luther, excited more indignation than terror among his followers, and gave a fresh impulse to the spread of the new doctrines. In some cities the people violently obstructed the promulgation of the bull; in others, the persons who attempted to publish it were insulted, and the bull itself was torn in pieces and trodden under foot. Luther, after renewing his appeal to the general council, published remarks on the papal bull; and being now persuaded that Leo had been guilty both of impiety and injustice in his proceedings against him, assumed a bolder tone, and declared the pope to be that man of sin, or Antichrist, whose appearance is foretold in the New Testament. He declaimed against his tyranny and usurpations, and exhorted all Christian princes to shake off such an ignominious yoke. Nor did he stop here. As Leo had, in execution of the bull, appointed Luther's works to be burnt at Rome, the latter, by way of retaliation, assembled all the members of the university of Wittenberg, and with great pomp, in presence of a vast number of spectators, cast the volumes of the canon law, together with the bull of excommunication, into the flames; and his example was imitated in several cities of Germany. This took place on the 10th of December, 1520; and on the 6th of the ensuing month the pope launched a second bull against him, by which Luther was finally expelled from the communion of the church. Thus separated from all connection with the see of Rome, Luther applied himself more assiduously than ever to the study of the word of God as the only standard of theological truth; and while he was thus enabled to attack with the greater success most of the peculiar papal doctrines, both theological and ecclesiastical, he exposed, at the same time, the immoral and secular lives of the clergy; and thus laid the foundation of that reformation of religion which at first he never contemplated, but which has been characterized "as a revolution in the sentiments of mankind, the greatest as well as the most beneficial that has happened since the publication of Christianity." (*Robertson's Charles V.*, 8vo. ed. vol. ii. p. 12.)

A spirit of inquiry having, by means of Luther's preaching and publications and the violent procedure of the court of Rome, been excited in the public mind, the progress of the reformed doctrines was rapid and general, and threatened to embrace the whole of Germany, notwithstanding the Emperor Charles V. co-operated with the pope to check and destroy them. Luther, too, was protected, from various motives, not merely by the Elector of Saxony, but by many other princes; and the new views were adopted and sedulously propagated by Melanchthon, Carlostadius, and other eminent men. Erasmus, too, though he did not long follow in the same course as the German reformer, and ultimately wrote against some of his views, yet discovered and exposed, with great learning and ability, many errors both in the doctrine and worship of the Romish church, and may be considered as his auxiliary in the work of reformation.

Under such circumstances it was that the imperial diet at Worms was held, January, 1521, to which the different princes were invited, in order to concert the most proper measures for checking the progress of those new and dangerous doctrines which threatened to disturb the peace of Germany, and to overthrow the religion of their ancestors. An attempt to condemn him in his absence was frustrated by a majority of the members of the diet; and Luther, under a safe-conduct, was summoned to appear before them. He did not hesitate to attend; but neither threats nor entreaties could induce him to retract any of his opinions, or to consent to their being tried by any other rule than the word of God. He was allowed to leave the city in safety; but an edict was published in the emperor's name, after his departure, putting him under the ban of the empire. The circumstances, however, in which Charles was placed, — the commotions in Spain, and the wars in Italy and the Low countries, together with the prudent precaution of the Elector of Saxony in concealing Luther in the castle of Wartburg, all concurred in preventing the edict being carried into effect. During his confinement his opinions continued to gain ground; and the Augustinians of Wittenberg ventured on an alteration in the established forms of public worship, by abolishing the celebration of private masses, and by giving the cup as well as the bread to the laity in administering the sacrament of the Lord's Supper. In a short time, however, the new views were condemned by the university of Paris, and a refutation of them was attempted by Henry VIII. of England. But neither of these intimidated Luther. He published animadversions on both with as much virulence as if he had been dealing with an ordinary adversary.

Meanwhile an attack no less violent, occasioned by a similar cause, was made on the Romish church in Switzerland. The Franciscans being intrusted with the sale of indulgences in that country, executed their commission with the same indiscretion and rapaciousness which had rendered the Dominicans so odious in Germany. But they were met and opposed (1518) by Zuinglius, a man not inferior to Luther himself in zeal and intrepidity, and who advanced with perhaps more daring and rapid steps to overthrow the whole fabric of the established religion. Notwithstanding that the universities of Cologne and Louvain pronounced his doctrines to be erroneous, the cantons of Zurich, Berne, Basil, and Schaffhausen embraced his opinions. Several conferences were at different times held between the Roman Catholics and the "Evangelicals," as the followers of Zuinglius

were called; and all of them tended to the spread of the reformed faith. After a conference held at Berne in 1528, the council of that canton, considering the result to be in favour of the Evangelicals, published ten theses, which embodied the substance of the Reformation in Switzerland; and most of the leading principles contained in them are acknowledged by the reformed churches generally, however widely they may differ among themselves on some abstruse points.

The Swiss and the German reformers were at first unacquainted with the proceedings of each other, though both were animated by the same spirit, and, in different places, pursuing a similar object. But, while they both resisted and exposed the usurpations and errors of the Romish church, and generally agreed in their sentiments, they entertained very different theological opinions; and thus was sown the seeds of those divisions which have since agitated the reformed churches. The chief subject of dispute between the two reformers was concerning the manner in which the body and blood of Christ were present in the Eucharist. Luther and his followers, though they rejected the papal belief of transubstantiation, were nevertheless of opinion that the body and blood of Christ were really present in the Lord's Supper, in a way which they could not pretend to explain. Zuinglius and his adherents repudiated the doctrine, and taught that the bread and wine used at the Eucharist were no more than external symbols to excite the remembrance of Christ's sufferings in the minds of those who received it. Both parties maintained their opinions with equal obstinacy; and as this dispute threatened to retard the great work of reformation, and to bring discredit on its adherents, the Landgrave of Hesse invited Luther and Zuinglius, with several of the most eminent of their respective followers, to a conference at Marburg, in order to promote unanimity and peace. After a disputation of four days, however, neither of the contending parties could be persuaded to abandon their views. But as both agreed in their sentiments not only as to the popish hierarchy, but as to the fundamental principles of Christianity, they parted in Christian charity, though not in brotherhood, agreeing to refrain from open controversy.

The struggle between the Roman Catholics and the reformers still raged in Germany. At the diet of the empire held at Spires in 1526, the emperor's ambassadors used their utmost endeavours to suppress all disputes about religion, and insisted on the vigorous execution of the sentence which had been pronounced against Luther and his followers at Worms. This attempt was successfully resisted by the majority of the members; and it was at last unanimously agreed to present an address to the emperor entreating him to call a general council without delay; and that the princes of the empire should in the meantime be allowed, in their respective dominions, to manage religious matters as they should think proper. These resolutions proved favourable to the cause of the Reformation, and gave an impetus to the expression of the public voice. The war in which at this time the emperor was engaged with the pope gave a decided advantage to the friends of the reformed faith, and greatly increased their number. At a diet, however, held in the same place in 1529, the power which had been given to princes of managing ecclesiastical affairs until the meeting of a general council was revoked by a majority of votes, and every change declared unlawful that should be made in the established religion before the determination of the approaching council was known. After many ineffectual remonstrances and arguments, six princes of the empire and thirteen imperial cities "protested" against this decision. Hence arose the denomination of "Protestants;" a term at first applicable only to the Lutherans, but now common to all who have separated from the church of Rome.

As the reformed doctrines in Germany had not yet been reduced to a system, the Elector of Saxony ordered Luther and other divines to commit to writing the leading articles of their religious system, along with the principal points on which they differed from the church of Rome. In compliance with this order, Luther delivered to the elector at Torgau seventeen articles, which had been agreed on at a conference at Sulzbach; hence called the Articles of Torgau. This declaration of the sentiments of the reformers was enlarged and rendered more minute and perspicuous by Melanchthon, who performed the task with equal ability and elegance.

In 1530, Charles convoked a diet of the empire at Augsburg, and directed the reformers to lay before it an account of their tenets in German and Latin. The work prepared by Luther and Melanchthon was presented to the diet; hence called the Confession of Augsburg, or *Confessio Augustana*, which was read aloud by the chancellor to the assembly. It contained twenty-eight chapters, of which twenty-one were illustrative of the religious opinions of the Protestants, and the remaining seven of the errors and superstitions of the papal faith. But after much disputation, not only was it rejected, but the diet published a decree condemning most of the peculiar tenets held by the Protestants, and forbidding any person to protect or tolerate such as taught them; enjoining a strict observance of the established rites, with other articles equally galling and tyrannical. But the Protestants were now too powerful a body, and their views had assumed so completely the form of a system that they were not easily dismayed. On the contrary, they assembled at Smalcalde, where they concluded a treaty of mutual defence, both religious and political, against all aggressors, and formed the Protestant states of the empire into one regular combination. Thus, in the year 1530, was the Reformation virtually established in Germany; first, by the publication of the Confession of Augsburg; and, second, by the league of Smalcalde, which made that creed the bond of union of a powerful political confederacy.

It may here be mentioned that the followers of Zuinglius, or Sacramentarians, as they were sometimes called, presented their confession of faith on the part of four cities, Strasburg, Memmingen, Lindau, and Constance; generally known by the Confession of Strasburg, or *Confessio Tetrapolitana*. The reformed cantons of Switzerland were not allowed to join the league of Smalcalde, inasmuch as they refused to sign the Confession of Augsburg; and thus the Swiss Evangelicals or Sacramentarians continued distinct from the Lutherans (as they still do), though they joined in a separate league with the city of Strasburg and the Landgrave of Hesse, who adopted their views. The Helvetic Confession of Faith, founded on the articles of Berne already referred to, was finally published in 1532. The reformed doctrines had early spread to Geneva; and John Cauvin, or Calvin, of that city, after the death of Zuinglius, carried them farther than the Swiss Protestants had done. He abolished all festivals except Sabbath, discarded all church ceremonies, used leavened bread for the sacrament, and taught the doctrines of predestination and election in all their rigour. (*See* PRESBYTERY, in this work.) Calvinism thus became the third great branch of the Reformation, Luther and Zuinglius being respectively at the head of the other two. The systems of Zuinglius and Calvin, however, gradually merged together, and they may now be considered as one, having the same confession of faith.

It would exceed the bounds to which we must necessarily confine ourselves in this article, were we to trace the history of the Reformed faith after the treaty of Smalcalde: that treaty, among other results (such as conferences, meetings of councils, particularly the celebrated council of Trent in 1549), gave rise to a war between the emperor and the Protestants. But the peace of Augsburg, in 1555, terminated those and similar calamities which had so long agitated the empire. The following are the leading articles of that peace: namely, that the Protestants who followed the Confession of Augsburg should in future be free from the jurisdiction of the pope, and from the authority and superintendence of the bishops; that all the inhabitants of the German empire should be at perfect liberty to judge for themselves in all matters, religious and ecclesiastical; that all persons, whatever be their religious opinions, should enjoy equal civil rights and privileges,—in other words, that a complete toleration in religious matters should obtain; and that all those who should persecute any person under religious pretences should be declared and treated as public enemies of the empire, invaders of its liberties, and disturbers of its peace. Thus was the Reformation finally established in many parts of Germany as it exists, without any very marked change either as to its extent or its principles, at the present day. The conditions on which this desirable object was obtained were honourable to both parties, both Catholic and Protestant, and, generally speaking, to the German character. This happy state of things was broken many many years after by the thirty years' war (1619—48); but the treaty of Westphalia, which terminated this war, confirmed the articles of the peace of Augsburg, and extended its benefits to the Calvinists as well as to the Lutherans. Equal religious rights and privileges were extended to all, as is still happily the case.

While these events were taking place in Germany and Switzerland, the spirit of inquiry, which had been evoked so signally in these countries, spread, and roused most of the nations of Europe to a greater or less extent from their mental inactivity or superstitious credulity: the doctrines of the Reformation found their way partially into France; also into Spain and Italy. Prior to Luther's death (1546) these doctrines had made many converts in the Netherlands; and in the time of Philip II. the "Seven United Provinces," which separated from the rest, proclaimed liberty of conscience, and adopted the tenets of Calvinism, to which they have ever since adhered.

About the year 1556, the Lutheran creed was adopted

as the state religion in Denmark and Norway. This creed was propagated in Sweden soon after Luther's rupture with the church of Rome, by Olaus Petri, one of his disciples. Both Lutheranism and Calvinism early gained an extensive footing in Poland, which they still retain. To Hungary and Transylvania a similar remark applies. The history of the Reformation in the British empire is well known, and need not be detailed here. Though the Protestant episcopal church is the established religion in Ireland, more than three fourths of the people of that country retain their hereditary attachment to the papal creed. Altogether, not more than a fourth of the population of Europe are Protestant; of the remainder, about two thirds still adhere to the Romish faith, — the two great exceptions being Turkey, where Mohammedanism is established; and the east of Europe and other contiguous provinces, where the Greek church prevails. Protestantism, besides, is the predominant religion in the United States, and in almost all the British colonies. See CHRISTIANITY.

Independently of the truth or falsehood of the doctrinal and other points on which the reformed church dissents from that of Rome, the Reformation was the cause of many interesting and important advantages. It burst the fetters by which the human mind had previously been bound, and restored it to liberty. It made religion an object of the understanding, and not of the eye; of the heart, rather than of the memory. "On the whole, the Reformation nas been an incalculable good to Europe; it has purified religion and morals; it has improved the intellect, and has guaranteed civil liberty." (*Dunham's Hist. of the Germanic Emp.* b. iii. c. 2.) It has contributed to improve even the church of Rome itself both in science and in morals. "The desire of equalling the reformers in those talents which had procured them respect; the necessity of acquiring the knowledge requisite for defending their own tenets, or refuting the arguments of their opponents; together with the emulation natural between two rival churches, engaged the Roman Catholic clergy to apply themselves to the study of useful science, which they cultivated with such assiduity and success, that they have gradually become as eminent in literature as they were, in some periods, infamous. The same principle occasioned a change no less considerable in the morals of the Romish clergy. Many of them have, in consequence, been distinguished for all the accomplishments and virtues which can adorn their profession; and differ greatly from their predecessors before the Reformation, both in their maxims and in their conduct." (*Robertson's Charles V.* vol. v. pp. 414-15.; *Hist. of the Great Reformation in Germany and Switzerland*, by D'Aubigné; F. Paul, *Hist. of the Council of Trent*, &c.)

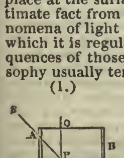
REFORMATION, JUBILEE OF THE. The two hundredth anniversary of the introduction of the Reformation at Geneva was solemnized under this title in August, 1835. The canton, since the Congress of Vienna, having become "mixed" in religion, the government took no part in this festival, the expenses of which were defrayed by voluntary subscription. Invitations were sent to the Protestant clergy of all countries, both Lutheran and Calvinist, to attend its solemnization: 61 were present from France, 12 from England, 3 from North America. The account of this great meeting is published under the title of *Jubilé de la Réformation de Génève*, Genev. 1835.

REFORMED CHURCH, comprises in a general sense all those bodies of Christians that have separated from the church of Rome since the era of the Reformation; but it is applied in a restricted sense to those Protestant churches which did not embrace the doctrines and discipline of Luther, and more particularly to the Calvinistic churches on the Continent.

REFRA'CTION. (Lat. refractus, *broken*.) In Mechanics, the change of direction which takes place in the motion of a body when it passes obliquely out of one medium into another of different density. The term is chiefly applied to the deviation from their rectilinear course of the rays of light in passing through transparent substances.

REFRACTION OF LIGHT. The deviation of a ray of light from its original path in entering a medium of a different density. This change of direction, which takes place at the surface of separation of two media, is the ultimate fact from which many of the most interesting phenomena of light receive their explanation. The laws by which it is regulated, and the investigation of the consequences of those laws, form the branch of natural philosophy usually termed *Dioptrics*.

(1.)



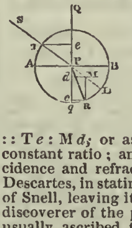
The phenomenon may be observed as follows: — Suppose a beam of light proceeding from a luminous point S (fig. 1.) to be admitted through a small hole A in the side of a vessel A B; then, the vessel being empty, the light will fall on the bottom at a point L in the same straight line with S and A. Now let water be poured into the vessel, and suppose the beam of light to fall on the surface of the water at P; then it will be seen that the light no longer continues its course in the same straight line, but is bent, or *refracted*, at P, and proceeds through the water in a straight line PR, more nearly perpendicular to the surface. A similar deviation takes place in all cases in which light passes from one transparent medium into another; but the magnitude of the angle R P L, or the amount of the refraction, varies according to the nature of the two media, and the degree of obliquity with which the incident ray falls on the surface of separation.

Through P draw Q P q a normal to the surface; then S P Q is *the angle of incidence*, R P q is *the angle of refraction*, and the following laws are found to be observed in all cases: —

1. The refracted ray P R is in the same plane with S P and P Q; that is, with the incident ray and the perpendicular to the surface at the point of incidence.
2. The incident ray S P and the refracted ray P R are always on opposite sides of the perpendicular Q P q.
3. Whatever be the inclination of the incident ray to the surface, the sine of the angle of incidence has to the sine of the angle of refraction a constant ratio.

These three laws, which hold good for curve surfaces as well as for planes, enable us to determine the path of the refracted ray with mathematical precision when the form of the surface and the nature of the refracting medium are both known. The two first are easily verified, and have been known from the days of Ptolemy. The third, which is very remarkable, was first enunciated in the *Dioptrics* of Descartes, published in 1637; but the discovery belongs to Willebrod Snell, professor of mathematics at Leyden, who died at an early age in 1626. Snell, indeed, made no mention of the sines of the two angles, but the relation which he affirmed to subsist is identical with the law as stated by Descartes. Through P (fig. 2.), the point of incidence, as a centre, let a circle be described meeting the incident ray in T and the refracted in R, and through R draw RM perpendicular to the surface A B, meeting P L in M; draw also R c, M d, T e, respectively perpendicular to Q q. Now the proposition affirmed by Snell was, that for every inclination of S P to the surface the line P R is to P M in a constant ratio. But P R = P T, and PT : P M :: T e : M d; or as T e : R c, therefore T e is to R c in a constant ratio; and these are obviously the sines of incidence and refraction respectively to the same radius.

(2.)



Descartes, in stating the law of the sines, made no mention of Snell, leaving it to be inferred that he himself was the discoverer of the property in question, which, in fact, is usually ascribed to him by the French authors. It is, however, by no means certain (though asserted by various writers) that Descartes was acquainted with what had been done by Snell, as the work of the latter existed only in manuscript when the *Dioptrics* made its appearance.

Let i denote the angle of incidence, r the angle of refraction, and let $n : 1$ be the constant ratio of the sines in passing from a given medium A into another given medium B; we have then, by the third law above stated, $\sin. i = n \sin. r$, for every value of i. The quantity n, which is constant for the same two media, is greater than unity when the refracting power of the first medium A is less than that of the second B, and *vice versâ*. Its value must be determined in every case by experiment; and as it is relative to both media, it is convenient for the purpose of comparing the refractive powers of different substances to refer them all to some common medium A, usually assumed to be an absolute void, and in this case the quantity n is called the principal index of refraction of the medium B, or simply *the index of refraction*. We have therefore this definition: —

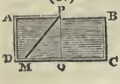
The index of refraction of any transparent substance is the ratio of the sine of incidence to the sine of refraction, when light passes from a vacuum into the substance.

As there is no known substance of such a nature that light entering it from a vacuum is refracted so as to make the angle of refraction greater than the angle of incidence, the index of refraction is always greater than unity. Of all known substances, that which possesses the greatest refractive power is chromate of lead, for which the index of refraction is 3; hence in the equation $\sin. i = n \sin. r$, all the values of n which have yet been experimentally determined lie between 1 and 3.

From the formula $\sin. i = n \sin. r$ some remarkable consequences are readily deduced. Suppose i to have its greatest value, namely $90°$, in which case the incident ray becomes parallel to the surface of the medium. We have then $\sin. i = 1$; and the formula becomes $1 = n \sin. r$, whence $\sin. r = 1 \div n$, which is the limiting value of r. In the case of water the index of refraction $n = 1{\cdot}336$ (or nearly $\frac{4}{3}$), and the arc whose sine is the reciprocal of this quantity is $48° \, 27' \, 40''$; consequently light cannot enter water more obliquely than under an angle of $48° \, 28'$

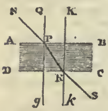
Thus, suppose a vessel A B C D (fig. 3.) to be filled with water, and a part of the surface A P to be covered over; then on drawing a line P M, making with the perpendicular P Q an angle M P Q = 48° 28′, the part A P M D will remain in perfect darkness, however the uncovered part of the surface P B may be illuminated.

(3.)



It is a principle in optics, that if a ray of light passes from a point A to a point B after any number of refractions or reflexions, a ray will pass from B to A by following precisely the same course in an opposite direction. From this it follows that if a ray of light S P (fig. 4.) falling on the exterior surface A B of a medium is refracted into the direction P R, then on arriving at the interior surface C D it will suffer another refraction, and escape from the medium in the direction R s, making with K k (the perpendicular to C D at R), the angle s R k equal to the angle S P Q. With respect to the surface C D, P R K becomes the angle of incidence, and k R s the angle of refraction; and if we suppose the ray to pass from the medium into a vacuum, and n to be the index of refraction of the medium, we have $\sin. i = \frac{1}{n} \sin. r$.

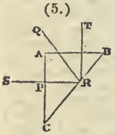
(4.)



Now since n is greater than unity, r is greater than i; and if we suppose those angles to increase until r, or the angle k R s, becomes a right angle, then $\sin. r = 1$, and we have $\sin. i = 1 \div n$ for the limiting value of i, beyond which the ray will not leave the surface at R; for if $\sin. i$ be greater than $1 \div n$, it follows that $\sin. r$ must be greater than unity, which is impossible. Hence it follows that if the ray P R fall upon the interior surface, making with the normal K R an angle greater than $1 \div n$, it will not leave the medium, but be reflected internally from R.

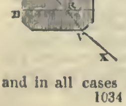
This property admits of various practical applications. For ordinary glass the value of n is about $\frac{3}{2}$, so that in passing from glass to air we have $\sin. i = \frac{2}{3} \sin. r$. Now let i increase until $r = 90°$, then $\sin. i = \frac{2}{3}$, whence $i =$ 41° 49′, which therefore is the limiting value of the angle of incidence when light passes from glass into air. Let A B C (fig. 5.) be a triangular glass prism having the angle at A a right angle, and the sides A B and A C equal, so that B and C are each angles of 45°; and conceive a ray of light S P to fall perpendicularly on the surface A C at P. This will continue its course through the glass in a straight line until it meets the side B C in R, making with R Q (the normal to B C) the angle of incidence S R Q = 45°. But this angle being greater than 41° 49′, the ray will not leave the medium, but be reflected at the interior surface in the direction R T, which, since the angles of incidence and reflexion are equal, will be perpendicular to S R, so that the ray will fall perpendicularly upon the surface A B, and pass through it without refraction. The prism thus produces the same effect as a diagonal mirror placed in the plane B C.

(5.)



When the index of refraction for each of two media has been determined, the refraction which takes place in passing from the one medium to the other is also known, the constant ratio of the sines of incidence and refraction being, in this case, the ratio of the indices of the two media. Let m be the index of refraction for the medium A, and n the index for the medium B; then, in passing from A into B, we have $\sin. i = \frac{n}{m} \sin. r$. Thus, the index of refraction for water is 1·336, and for amber 1·547; therefore in passing out of water into amber the constant ratio of the sines of incidence and refraction will be 1·158, the quotient which arises from the division of 1·547 by 1·336. An immediate consequence of this is, that when a ray of light enters a medium after having passed successively through several others, the path of the ray in the last medium will be the same as if it had entered that medium directly under the same angle of incidence as that by which it entered the first; and if the media are bounded by parallel surfaces, the direction of the ray after escaping from the last surface will be parallel to its primitive direction. Thus, let the ray S P (fig. 6.), entering the medium A at P, be refracted into the direction P R, and on entering the second medium B be again refracted into the direction R V, the path of the ray V X after leaving the second medium will be parallel to S P, provided the surfaces at P and V are parallel; and in all cases the ray will emerge at V under the same angle of obliquity as it entered the first surface at P.

(6.)



The principles which have now been laid down are sufficient to enable us to compute the path of a ray of light through any diaphanous substance, or through different substances in succession, when the index of refraction belonging to each substance is known. The following table (from *Brewster's Optics*, *Cab. Cyclopedia*, p. 370.) gives the indices of refraction for the greater part of the substances which have yet been examined.

TABLE of the Refractive Powers of Solid and Fluid Bodies.

	Index of Refraction.		Index of Refraction.
Realgar, artificial	2·549	Plate glass, from 1·514 to	1·542
Octohedrite	2·500	Crown glass, from 1·525 to	1·534
Diamond	2·439	Oil of cloves	1·535
Nitrite of lead	2·322	Balsam of capivi	1·528
Blende	2·260	Gum arabic	1·502
Phosphorus	2·224	Oil of beech nut	1·500
Sulphur melted	2·148	Castor oil	1·490
Zircon	1·961	Cajeput oil	1·485
Glass — lead 2 parts, flint 1 part	1·830	Oil of turpentine	1·475
Garnet	1·815	Oil of olives	1·470
Ruby	1·779	Alum	1·457
Glass — lead 3 parts, flint 1 part	2·028	Fluor spar	1·434
Sapphire	1·794	Sulphuric acid	1·434
Spinelle	1·764	Nitric acid	1·410
Cinnamon stone	1·759	Muriatic acid	1·410
Sulphuret of carbon	1·768	Alcohol	1·372
Oil of cassia	1·641	Cryolite	1·349
Balsam of Tolu	1·628	Water	1·336
Guiacum	1·619	Ice	1·309
Oil of anise seed	1·601	Fluids in minerals, 1·294 to	1·131
Quartz	1·548	Tabasheer	1·111

TABLE of the Refractive Powers of Gases.

	Index of Refraction.		Index of Refraction.
Vapour of sulphuret of carbon	1.001530	Carbonic acid	1·000449
Phosgene	1·001159	Carburetted hydrogen	1·000443
Cyanogen	1·000834	Ammonia	1·000385
Chlorine	1·000772	Carbonic oxide	1·000340
Olefiant gas	1·000678	Nitrous gas	1·000303
Sulphurous acid	1·000665	Azote	1·000300
Sulphuretted hydrogen	1·000644	Atmospheric air	1·000294
Nitrous oxide	1·000503	Oxygen	1·000272
Hydrocyanic acid	1·000451	Hydrogen	1·000158
Muriatic acid	1·000449	Vacuum	1·000000

In the preceding remarks light has been regarded as a homogeneous substance, all the parts of which have the same index of refraction. This however, is not the case; refraction never takes place without a separation of the differently coloured rays, so that for every transparent body the index of refraction changes with the colour of the light. The numerical values of the indices, given in the above table, correspond to the yellow or green rays which occupy the middle of the dispersed pencil. For the different refrangibilities of the primary rays, see CHROMATICS, DISPERSION, SPECTRUM.

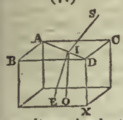
Double Refraction. — The phenomena and laws of refraction, which have yet been considered, belong to those cases in which a single refraction takes place on the entrance of light into a different medium, or in which a pencil of light on entering a refracting medium continues to form a single pencil, and to afford a single image of the object from which it proceeds. There are, however, a multitude of substances which, either in their natural state or under accidental circumstances, exercise a peculiar influence on light, causing it, in its passage through them, to follow two distinct paths, forming with each other an angle of greater or less amount. Such substances are called *doubly refracting substances*, and the phenomenon itself is called *double refraction.*

The substances or media which produce only single refraction belong to one or other of the four following classes: — 1. Gases and vapours. 2. Fluids. 3. Substances which have passed from the liquid to the solid state so rapidly as to prevent the molecules from taking a regular crystalline arrangement: for example, glass, glue, &c.; gums, resins, &c. 4. Crystals whose primitive form is the cube, regular octahedron, or rhomboidal dodecahedron, or which belong to the tessular system of Mohs. All other substances, as the salts, precious stones, crystals not belonging to the above-named forms; all bodies belonging both to the animal and vegetable kingdoms, in which there exists any disposition to a regular arrangement of the molecules, as horn, mother of pearl, &c.; and in general all bodies unequally compressed, or which have not the same structure in all directions, separate the light which they refract into two distinct pencils, which

pursue separate courses, and are governed by totally different laws.

In order to give an idea of this remarkable phenomenon,

(7.)



let A B C D X (fig. 7.) be a crystal of Iceland spar (carbonate of lime), having its faces made smooth either by cleavage or by grinding, and let it be laid on one of its faces on a sheet of white paper over a black spot O; then, on looking through the crystal, two spots will be seen, one at O, and the other at E. On turning the crystal round on its axis, but always keeping the same face on the paper, one of the images, O, will remain invariable, while the other, E, will appear to describe a circle about O. If instead of a round spot the object viewed be a straight line; then, on looking through the crystal, a double image of the line will be seen, one passing through O, and the other through E. On turning the crystal as before, it will be seen that the distance between the two lines varies, but that they always remain parallel to each other; and that in the course of a complete revolution of the crystal about its axis there are two positions in which the images will coincide, and two other positions, midway between the former, in which they will attain a maximum distance. These phenomena show that a ray of light, S I, on entering the face of the crystal at I, is separated by refraction into two pencils, I O and I E; and it is found that on emerging from the crystals the two pencils make the same angle with the surface, and continue their course in a direction parallel to each other and to the incident ray S I.

If we cause a beam of solar light to fall on the crystal, and examine the paths of the two pencils, it will be found that I O follows the laws of ordinary refraction, the sine of incidence being to the sine of refraction in a constant ratio, and the pencil continuing in the same plane with the incident ray and the normal to the surface at the point of incidence: hence I O is called the *ordinary* pencil. But I E is found to follow an entirely different law, and is therefore called the *extraordinary* pencil. If, for example, the incident ray S I is perpendicular to the face of the crystal, the ordinary refraction does not take place, the angle of incidence being zero; but in this case the angle of refraction of the extraordinary pencil, I E, is 6° 12′, and it is not in the same plane with the normal and the incident ray.

From a careful examination of the phenomena it is also found that although a ray of light falling on the face of the crystal is refracted generally into two pencils, there is one particular direction in which the incident ray undergoes only the ordinary refraction. This direction is parallel to A X, the shorter axis of the crystal, and is called the *axis of double refraction.* It is, therefore, to be observed that the axis of double refraction of a crystal is not a fixed line, but a determinate direction with reference to the faces of the crystal, every line parallel to A X forming an axis of double refraction. In some crystals the extraordinary ray is refracted *towards* the axis A X, in others it is refracted *from* it. In the first case the axis is called a *positive* axis of refraction; in the second it is called a *negative* axis.

In the crystal we have now been considering (Iceland spar), there is only one direction in which the double refraction does not take place, but in many other crystals there are two directions which have this property. In examining the phenomena of double refraction in a great number of crystallized substances, Sir David Brewster found that all those crystals whose primitive and simplest form has only one axis of figure, or one pre-eminent line about which the figure is symmetrical, have only one axis of double refraction. The primitive forms which have only one symmetrical axis of figure are the following:—

1. The rhomb with an obtuse summit; as Iceland spar, tourmaline, quartz, &c.
2. The rhomb with an acute summit; of which form are corundum, sapphire, ruby, cinnabar, and arseniate of copper.
3. The regular hexaedral prism; as emerald, beryl, arseniate of lead, &c.
4. Octohedron with square base; as zircon, oxide of tin, prussiate of potash, &c.
5. Right prism with square base; as arseniate of potash, phosphate of magnesia, &c.

In all these forms, and in the primitive forms to which they delong, the line A X is the axis of figure and of double refraction; and it is the only direction in which there is no double refraction. (See *Brewster's Optics*, p. 149.)

The property of possessing two axes of double refraction was discovered by Sir David Brewster in 1815, and he found that it belonged to all crystals, whether chemical bodies or mineral substances, which are included in the prismatic system of Mohs, or whose primitive forms are,

1. A right prism, base a rectangle.
2. A right prism, base a rhomb.
3. A right prism, base an oblique parallelogram.
4. Oblique prism, base a rectangle.
5. Oblique prism, base a rhomb.
6. Oblique prism, base an oblique parallelogram.
7. Octohedron, base a rectangle.
8. Octohedron, base a rhomb.

In all these forms there is no axis about which the crystal is symmetrical.

In all cases of crystals with two axes of double refraction, both the pencils are refracted according to the laws of extraordinary refraction. In a substance called analcime Sir D. Brewster found there were several planes along which if the incident ray passes it will not suffer double refraction, whatever be the angle of incidence. Each of these planes, therefore, may be considered as containing an infinite number of axes of double refraction, or lines in which there is no double refraction. No other substance has yet been found possessing the same property. (*Optics*, p. 155.)

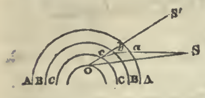
Another very remarkable property is, that in crystals which have only one axis of double refraction the axis has always the same position, being, in fact, in all cases, the axis of symmetry; but in crystals which have two axes of double refraction, the axes change their position according to the colour of the incident light. Sir John Herschel, to whom this discovery is due, found that in crystals of Rochelle salts the inclination of the two axes for violet light is 56°, while for red light it is about 76°. In other crystals, as nitre, the inclination of the two axes is greater for the violet than for the red rays; but in all cases the line which joins the extremities of the axes for all the rays is a straight line.

The property of double refraction was discovered by Bartholin, in 1669, and was first explained by Huygens on the hypothesis of the propagation of light by means of an elastic medium. The phenomena have been studied with great assiduity in modern times, and, in fact, the investigation of their laws forms one of the principal parts of physical optics, and has mainly contributed towards the establishment of the now generally received theory of undulation. Newton does not appear to have paid much attention to the subject, and his theory of emission does not very readily accommodate itself to the explanation of the phenomena; though it must be owned that the supporters of that theory have succeeded, by means of certain arbitrary hypotheses, in constructing mathematical formulæ which represent the greater part of the known facts. For the complete explanation of all the phenomena, the undulatory theory requires two postulates, or assumptions:—1. That the vibrations of the ether take place *transversely*, or in the direction perpendicular to the visual ray; and, 2. That the elasticity of the medium is unequally developed in the interior of the refracting crystal. The first of these assumptions is analogous to what takes place when a blow is given to a cord tightly stretched; the motion is communicated rapidly in the direction of its length, while the vibrations are at right angles to that direction. With respect to the second assumption, the facts which are known respecting the constitution of crystals render it exceedingly probable, *à priori*. All diaphanous bodies which refract light only in a single direction, and according to the Cartesian law, are found to have the same tenacity and the same elasticity in all directions, and their linear dilatations by heat are also the same; but it has been established that with respect to all crystallized substances, which possess the property of double refraction, the elastic force with which they resist compression is greater in certain directions than in others, and also that the linear dilatation corresponding to the same increase of temperature varies with the direction in which it is measured. These facts prove that the matter of the crystal possesses an elasticity varying with the direction; and it seems natural to suppose that the ether within it must have the same property. On these two assumptions, namely, transverse vibrations, and unequally developed elasticity of the medium, Fresnel has constructed a mathematical theory of double refraction, from which all the phenomena which have yet been observed are deduced as simple corollaries. (See *Sir J. Herschel's Treatise on Light*, *Ency. Metropol.*; *Airy's Mathematical Tracts*, 2d ed.; Pouillet, *Elemens de Physique*.)

REFRACTION, ASTRONOMICAL. Refraction, in Astronomy, is the apparent angular elevation of the celestial bodies above their true places, caused by the refraction of the rays of light in their passage through the earth's atmosphere.

It is found by experiment, that the refractive power of a gas, or aëriform substance, is proportional to its density. Now the earth's atmosphere is not a medium of uniform density, but of a density continually diminishing as the distance from the centre is increased. For the purpose of illustration, the atmosphere may be regarded as composed of a great but finite number of concentric spherical strata, each having a uniform density greater than that of the stratum by which it is enveloped, but less than

that of the stratum which it envelopes. Hence, on entering each successive stratum, the light must undergo a slight deviation from its rectilinear course, and the amount of all these deviations constitutes the phenomenon of astronomical refraction. Let A A, B B, C C, represent the boundaries of the successive strata, and suppose a ray of light proceeding from the star S to enter the highest stratum A A obliquely at a. If no deviation took place, the ray would continue to advance in the same straight line S a; but in consequence of entering a denser medium it is refracted, according to the law of Descartes, into a direction, $a\ b$, more nearly perpendicular to the surface of the spherical stratum. At b it again enters a medium of a greater density, and is refracted into the direction $b\ c$, still approaching the perpendicular to the surface. On arriving at c the phenomenon is repeated, and the ray is bent from the direction $b\ c$ into the direction c O; so that in passing from S to O the ray of light, instead of describing the straight line S O, describes the polygon S $a\ b\ c$ O, and to a spectator at O the star will appear to be situated at S′ in the direction O c. Hence the star appears to be elevated above its true place; and the angle S′ O S, which is the difference between its true and apparent elevations, is the *astronomical refraction*. If we suppose the number of the strata to become infinitely great, then the angular deviation at each successive stratum will become infinitely small; and the path of the ray, instead of being a polygon, will be a continuous curve, which, according to the laws of refraction, will lie wholly in the same vertical plane.



Since the ratio of the sines of incidence and refraction is constant, it is evident that the total effect will be the greatest when the luminous rays enter the atmospheric strata with the greatest obliquity; that is to say, when the object is seen in the horizon. At the zenith there is no refraction; in descending from the zenith to the horizon it continually increases, according to a certain law, which may be determined theoretically if the refractive power of atmospheric air at a given density and temperature, the dilatation of air by heat, and also the law of the variation of the density and temperature in ascending into the higher regions of the atmosphere, are supposed to be known. At a medium density, and at the temperature of melting ice, Biot and Arago found by experiment that for any altitude exceeding 10° above the horizon the law of atmospheric refraction is represented by the formula $r = 60''\cdot 6$ tan. $(Z - 3\cdot 25 \times r)$, in which r is the refraction corresponding to a given zenith distance Z. Bradley had given the formula $r = 57''$ tan. $(Z - 3\cdot 25\ r)$. From either of these it appears that the increase of refraction is nearly proportional to the tangent of the zenith distance, but at low altitudes the expression becomes much more complicated.

The following table given by Mr. Ivory (*Phil. Transactions* for 1838, part 2.) shows the amount of refraction at different zenith distances, the temperature being 50° of Fahrenheit, and the height of the barometer 30 inches. The correction (omitting some small terms) for the actual temperature and barometric pressure is obtained by multiplying the tabular refraction by $\frac{1}{1 + c\,(t - 50)} \cdot \frac{b}{30}$, where b is the observed height of the barometer reduced to the fixed temperature of 50° Fahr., t the temperature of the air on the same scale, and $c = \cdot 002183$.

Zenith Distance.	Refraction.	Zenith Distance.	Refraction.
10°	10·30″	82°	394·68″
20	21·26	83	445·42
30	33·72	84	509·86
40	48·99	85	593·96
45	58·36	85½	646·21
50	69·52	86	707·43
55	83·25	86½	779·92
60	100·85	87	866·76
65	124·65	87½	971·93
70	159·16	88	1101·35
75	214·70	88½	1262·6
80	320·19	89	1466·8
81	353·79	89½	1729·5

The existence of astronomical refraction was known at an early period, though its amount and laws have only been ascertained in recent times. Ptolemy, in his book on *Optics*, remarks that in consequence of refraction a star is brought nearer the zenith, and that the effect is greater in the case of a low than a high star; but as no mention is made of the subject in the *Almagest*, it was not then regarded as an element of astronomical calculation. Similar notions appear in the *Optics* of Alhazen. Walther was the first who began to estimate the effects of refraction near the horizon; and Tycho Brahe constructed, from observations, the first table. He supposed the horizontal refraction to be 34′, which is very near the truth (its mean amount being 33′); but he supposed it to vanish at the altitude of 45°, though its mean amount at that altitude appears, by the preceding table, to be nearly 1 minute. Dominic Cassini gave an empirical formula for computing the refraction at any altitude; but the solution of the problem on true principles was first undertaken, and, in fact, fully accomplished, by Newton, though his results did not represent the observations, in consequence of the imperfect knowledge which then existed respecting the physical constitution of the atmosphere.

REFRACTION, TERRESTRIAL. The atmospherical refraction, which has just been explained, is the effect produced by the whole atmosphere on a body placed entirely beyond it; but as the density of the atmosphere varies with the height, it is evident that the apparent place of any object placed on a different level from that of the observer must be affected in a greater or less degree by refraction. Whether the rays of light come from a more elevated object, and consequently pass from a rarer into a denser medium, or from an object depressed below the horizon of the observer, and consequently pass from a denser into a rarer medium, they are equally bent downwards, and consequently the apparent place of the object is raised. This refraction between terrestrial objects is called *terrestrial refraction;* and as the density of the air near the surface of the earth is liable to great irregularities from being irregularly heated, its effects give rise to many very remarkable phenomena. Among these are *looming* or *mirage*, the *fata morgana* (see the terms), and the occasional appearance above the horizon of distant objects which in the ordinary state of the atmosphere are invisible. Sometimes, in consequence of the rarefaction of the air in the neighbourhood of a surface of water, or of a building, or of the earth itself, a distant object appears to be depressed instead of being elevated; and occasionally it is at once both depressed and elevated, so as to appear double, in which case one of the images is generally seen in an inverted position, as if a reflexion had taken place. In very exact observations, as in geodetical surveys, it is found that the refraction is not always confined to the same vertical plane, but sometimes produces a deviation amounting to a few seconds laterally.

REFRACTIVE POWER, in Optics, is the degree of influence which a diaphanous body exercises on the light which passes through it. For the measure of this influence modern writers generally adopt the square of the index of refraction diminished by unity, or $n^2 - 1$, where n denotes the principal index of refraction. (*See* REFRACTION.) The reason of this is founded on certain dynamical considerations regarding the physical cause of refraction. According to the Newtonian theory of emission, the velocity of light is accelerated on entering a denser medium by reason of the increased molecular attraction; and the law of refraction is explained by supposing the index of refraction of any substance to be the ratio of the velocity of light in that substance to its velocity in a vacuum. Thus, let u denote the velocity of light in a vacuum, and v its velocity while passing through a diaphanous substance, then $v \div u = n$; or, since sin. $i \div$ sin. $r = n$, the sine of incidence is to the sine of refraction inversely as the velocity in a vacuum to the velocity in the medium. Now the increment of the *vis viva*, or the excess of the square of the new velocity above that of the former, is $v^2 - u^2$, and the ratio of this to the square of the former is $(v^2 - u^2) : u^2$, which is the same as the ratio of $n^2 - 1$ to unity.

According to the undulatory theory, the velocity of light is diminished on entering a denser body. In this case, $u^2 - v^2$ is the loss of *vis viva;* and the ratio $(u^2 - v^2) : v^2$, or $n^2 - 1$ to 1, is the ratio of *vis viva* which is lost to that which is retained. In either case, the ratio $n^2 - 1$ to 1 forms the measure of the *refractive power* of the substance of which n is the index of refraction.

Some modern authors employ the phrase *absolute refractive power* to denote the ratio of the refractive power of a substance (as above defined) to its density; that is to say, the ratio $(n^2 - 1) : D$, where D stands for the density of the body. Sir Isaac Newton (*Optics*, p. 247.) calls this the "refractive power of a body in respect of its density;" and, as it is a consequence of the theory of emission that the refractive power must be proportional to the density, the ratio $(n^2 - 1) : D$, according to this theory, is constant for the same medium; that is to say, its numerical value depends only on the nature of the medium, and is independent of its condition; so that a liquid and its vapour ought to have the same absolute refractive power, which is contradicted by the experiments of Arago and Petit.

The French authors use the term *puissance réfractive* to denote the refractive power, or the number $n^2 - 1$, while they express the *absolute refractive power*, or the ratio $(n^2 - 1) : D$, by the term *pouvoir réfringent*. It is convenient to have different names for the two things, which are totally different, at least in their numerical measures. Thus hydrogen gas has a smaller index of refraction, and consequently a smaller refractive power,

than any other substance; but its *absolute refractive power*, or *pouvoir réfringent*, is greater than that of any other substance. (For a table of the values of the ratio ($n^2 - 1$) : D for a considerable number of different substances, see *Brewster's Optics, Cab. Cyclopædia.*)

REFRA'IN. The burden of a song, &c. See BURDEN.

REFRANGIBILITY, in Optics, is the disposition of the rays of light to be refracted or bent in passing obliquely from one transparent medium into another; but the term is chiefly used to denote the degree of that disposition possessed by the differently coloured rays. *See* REFRACTION, SPECTRUM.

RE'FUGE, CITIES OF. Six cities appointed, according to the words of Moses, under the Jewish dispensation (Deuteron. xix. 2. 9.), for the safety of those who had caused the accidental death of any one. If a deliberate murderer fled to one of these cities, the elders of the city were to deliver him "into the hands of the avenger of blood." The cities are enumerated in Joshua, chap. xx.

REFUGÉE. A name which has been given in history and political phraseology indiscriminately to persons who flee from religious or political persecution in their own country, and take refuge in another. It was originally applied to the French Protestants (refugiés) who found an asylum in this country, and among various Continental nations, after the revocation of the Edict of Nantes by Louis XIV.

REGA'LIA. (Lat. rex, *a king*.) In Politics, the privileges, prerogative, and right of property, belonging, in virtue of office, to the sovereign of a state. The latter class of objects are most commonly termed *regalia minora*; as, in some countries, waifs, strays, and newly-formed land, &c.; in England, forfeitures, &c.: while the former are known by the epithet *majora*. *Regalia*, in English Heraldry, the royal insignia, crowns, sceptres, globes, crosses, &c. used at the coronation: also the crown jewels. *Regalia* of the church, the privileges which have been conceded to it by kings; sometimes the patrimony of a church.

REGA'RDANT. (Fr.) In Heraldry, literally looking behind; applied to any animal whose face is turned towards the tail in an attitude of vigilance.

REGA'TTA. (Ital.) A word used originally by the Venetians to signify a grand fête, in which the gondoliers contested for superiority in rowing their gondolas; but the term has been adopted into all the languages of modern Europe, in which it signifies a brilliant species of boat race. In England, festivities of this species are almost of weekly occurrence during the summer season.

REGEL, or RIGEL. A star of the first magnitude, constituting the left heel of the constellation Orion.

REGENERA'TION. In Theology, the new birth of man unto righteousness, following on the abolition of the original corruption of his nature. Similar language was used respecting the admission of proselytes to the privilege of Judaism: so, also, in other religions. The Sanskrit name for a Brahmin is said to signify "twice-born;" and Tertullian says that the heathens used baptism in their mysteries, "in regenerationem." When our Saviour admonished Nicodemus not to marvel at his words, "Ye must be born again," he added, with reference, doubtless, to the doctrines already taught among the Jews, "Art thou a master of Israel, and knowest not these things?" (John, iii. 10.) That baptism is "a sign of regeneration," as expressed in the 27th Article of the Church of England, is admitted by nearly all Christians. (Rom. vi. 4. 11.; Tit. iii. 5.; John, iii. 5.) But whether the new birth to which allusion is made in these solemn passages actually takes place by and through baptism; whether baptism, duly administered by those authorized, is in itself an "opus operatum," in the language of the schools; or whether the regeneration spoken of as the condition of our salvation takes place after, and independent of baptism, by the operation of the Spirit on the inner man — this is a question on which Protestants have never agreed among themselves, and which divides our church at this day. The former is the commonly received or Catholic doctrine; and has been so from very early times, as far as we can conclude from the language of the fathers and ancient forms of the church. But it does not appear to be positively declared by the Church of England, though inferred from various passages in the baptismal service.

RE'GENT. (Lat. rego, *I govern*.) The person who exercises the powers of a sovereign during the absence, incapacity, or minority of the latter. In most hereditary governments the maxim is, that this office belongs to the nearest relative of the sovereign capable of undertaking it; but this rule is subject to many limitations. The kings of France exercised at various periods the power of fixing, by ordinance or will, the regency, in case of their decease leaving issue under age; and also the period of their son's majority. Nevertheless, these wills have been at various times disregarded in favour of what was esteemed the principle of the monarchy. Thus, the testament of Louis XIII., by which he declared his wife future regent, but limited her power in the essential prerogative of the choice of a council, was set aside as to this limitation, and she was appointed regent with full prerogatives. The testament of Louis XIV., as to a regency during the minority of Louis XV., was set aside by the parliament of Paris immediately after his death. In England, the right to appoint the regent is now fully recognized to belong to parliament; although, in 1788, on the occasion of the first illness of George III., much discussion took place as to the absolute right which some supposed to inhere in the heir apparent. The regency, in the event of the demise of the present sovereign leaving issue, is vested by act of parliament in her Majesty's consort.

RE'GENT MA'STERS, or REGENTS. In the English Universities, a term borrowed from the ancient usages of the University of Paris. In that institution graduates in the faculties, within a certain period after their degree, had the privilege, which they were bound to exercise, of giving public lectures (docendi, legendi, regendi scholas). The same custom was adopted at Oxford and Cambridge; although the regent masters were at an early period succeeded in the performance of this office by the established professors. The regents still form the governing body of the universities, in the convocation and congregation at Oxford, and in the academical senate of Cambridge. *See* MASTER OF ARTS.

RE'GICIDE. (Lat. rex, *king*, and cædo, *I kill.*) The offence of slaying a king or other sovereign. The early Greek republics, unaccustomed to the legitimate rule of monarchs, saw, in the occasional subjugation which they underwent from successful partisans, a mere usurpation, or tyranny; and tyrannicide was with them only the slaying of a public enemy. And the hatred which attached itself in the minds of the Roman people to the royal name and authority made them regard the acts of the elder and younger Brutus, even to the latest days of the republic, and long after the establishment of the empire, as virtuous and honourable. Hence the perverted morality on this peculiar subject which continues to prevail, more or less, even to the present day, as false in logic as contrary to the plain rules of conscience; for it is obvious that, to each individual, a wealthy or powerful oppressor, who commits injuries against him and his friends for which the law can give him no redress, is just as fair a subject for illegal vengeance as a king to any member of the community. Yet no one ever sought seriously to set up the right of assassination in such cases; as Buchanan, Languet, Mariana, and others have done in that of kings. English history has three notorious instances of kings (Edward II., Richard II., and Edward V.) murdered by powerful and rebellious subjects. But France, above all other countries, is fertile in examples of regicide, effected or attempted by private individuals under the influence of religious and political fanaticism. Henry III. and IV. both fell by the hands of Roman Catholic zealots. The reader will find in the Discourse of Père Mathieu on the Death of the latter (lately republished in *Cimber, Archives Curieuses*), a singular example of the fanaticism of cruelty in the way of retaliation, excited, and not unnaturally, by the repetition of such monstrous and desperate acts. But the savage execution of Ravaillac did not deter Damien, in the reign of Louis XV., from attempting the same offence from the same motives. The murder of the Duc de Berri, and the repeated attempts on the life of Louis Philippe, from political enthusiasm, show but too plainly that the morbid passions which actuated these celebrated assassins have but taken in modern times another direction. The murder of Gustavus, king of Sweden, by Ankarstrom, is, perhaps, the most deliberate instance of this crime on record; for the criminal, though rancorous and determined, was no zealot. It must be added, that the application of the term regicide to the members of the commission which sat in judgment on Charles I., and to the majority of the convention which condemned Louis XVI., is a violation of that moral sense which judges unerringly of actions; whatever the character of their conduct might be, it was altogether different from assassination; and to confound Vane or Carnot with Ravaillac and Fieschi, under a similar designation, can serve no ends but those of temporary party malice.

RE'GIMENT. (Lat. rego, *I rule.*) A body of troops consisting (if infantry) of several battalions, or (if cavalry) of several squadrons, under the command of a colonel. The British army consists, at present, of three regiments of horse guards; sixteen regiments of cavalry, of which four are heavy dragoons, five light dragoons, four hussars, and four lancers; three regiments of foot guards, divided into the grenadier guards, the Scots fusiliers, and the Coldstream guards; and ninety-nine regiments of infantry, exclusive of the royal regiment of artillery, and the royal corps of marines. Many of the regiments in the British army are distinguished by the name of the counties or districts where the men were originally enlisted. Thus the 3d regiment is called the

East Kent regiment; the 6th, the Royal Warwickshire, &c. &c. No rule is established with regard to the number of men of which a regiment should consist: both in England and on the Continent this point is settled either by the exigencies of service in time of war, or the principles of economy in time of peace. In the British army, the three regiments of horse guards consist at present each of 32 officers, 53 non-commissioned officers, 351 privates, and 274 horses. The ordinary cavalry regiments have each at an average 27 commissioned officers, 31 non-commissioned officers, 304 privates, and 283 horses. The grenadier regiment of guards consists of three battalions; and has 96 officers, 177 non-commissioned officers, and 2080 privates. The other two regiments of foot guards consist also of two battalions each, and have each 61 officers, 109 non-commissioned officers, and 1280 privates. The royal regiment of artillery consists of nine battalions, having 449 officers and 6062 non-commissioned officers and men, exclusive of the horse brigade, the engineers, and sappers and miners. (*Stat. of the Brit. Empire*, vol. ii. p. 433.)

RE'GISTER, LORD; or LORD CLERK REGISTER. A Scottish officer of state, who has the custody of the archives; hence also termed custos rotulorum. He was of old the principal clerk of the kingdom, from whom other clerks derived their authority. The office was formerly at pleasure, but since 1777 for life. Salary 1200*l*. a-year. He is assisted in his duties by a resident deputy.

RE'GISTRY OF BIRTHS, MARRIAGES, AND DEATHS. Down to the year 1836, in consequence of the defects of the system of registration, no complete or accurate information could be obtained as to the amount of births, marriages, and deaths throughout England; but at that period the necessity of having it superseded by a better system was admitted, which was finally accomplished by the act 6 & 7 Will. 4. c. 80.

This act, passed in pursuance of the recommendation of a committee of the House of Commons on parochial registers (1833), embodies a plan for the effectual registration of births, deaths, and marriages in England and Wales. To give uniformity to the system, it is conducted under the superintendence of an officer resident in London; and there also a central place of deposit is provided for certified copies of all parochial registers, with ready means of finding any entry in them. It is provided that in every case of *birth* the following circumstances shall be recorded: — viz. the time and place of birth; the name (if any) and sex of child; name and surname of father; name and maiden surname of mother; rank or profession of father; the signature, description, and residence of the informant; and also the baptismal name of child, if added after registration of birth. In every case of *death* the register is to record the time and place of death; the name and surname, sex, age, and rank or profession of the deceased; *the cause of death;* and the signature, description, and residence of the informant. In all cases the entries must be signed by the informant, and also by the registrar, who discharges this duty without any immediate expense to the parties requiring registration, his remuneration being derived from moderate fees paid out of the poor's rates. The insertion of the cause of death, along with the period of death, and the residence, sex, age, and occupation of the deceased, will, in time, afford data of the utmost importance to medical science, and to the improvement of vital statistics.

The central office in London for the deposit of certified copies of registers, and the general supervision and conduct of the business of registration, is called the General Register Office. It is presided over by a registrar-general appointed under the great seal, having under him an assistant registrar, chief clerk, and a numerous body of subordinate clerks. From this office communications emanate to all superintending registrars, registrars of births and deaths, and registrars of marriages, who all act within their respective districts under the directions of the registrar-general, in whom is vested the power of dismissal.

There are at present 619 superintendent registrars, who may each appoint a deputy, with the approval of the registrar-general. Of these superintendents 562 have accepted the office as clerks of boards of guardians for the poor, or have been appointed by the guardians, and 57 have been appointed by the registrar-general. Each superintendent registrar serves within the district to which he is appointed, which comprises one or more registrar's districts.

There are 2197 registrars of births and deaths, who may each appoint a deputy, with the approval of the guardians, or of the poor law commissioners. Of these registrars, 1981 have been appointed by the boards of guardians established under the Poor Law Amendment Act; and 216 are registrars of temporary districts, appointed by the poor law commissioners. Each registrar is appointed to some one of the 2197 registrars' districts, into which the whole of England and Wales has been divided: and he must reside in that district, and register *all* births and deaths that occur in it.

Marriages are registered, 1st, By clergymen of the established church, of whom 11,694 have been furnished with books for this purpose. 2dly, By registrars of marriages, of whom there were, on the 1st of January, 1838, 716: these last are appointed by the superintendent registrars, and register marriages solemnized in their presence in registered places of worship, or in the superintendent registrar's office; 297 of the total number of 716 are also registrars of births and deaths. 3dly, By the registering officers of Quakers, of whom there are 90. And 4thly, By the secretaries of synagogues, of whom there are 36.

The clergyman, and the various officers, amounting in all to about 14,400, to whom the business of registration is committed, are bound to make quarterly deliveries of *certified copies* of all entries in their respective registers during the previous quarter, to the superintendent registrars of the district to which they respectively belong; and these certified copies are transmitted by the superintendent registrars to the registrar-general. The certified copies are made on separate leaves of paper of a uniform size and peculiar texture, having a distinguishing water-mark. On being received at the general register office in London (whither they are sent by post), they are carefully examined; and any defects being noted, are made the subject of communication with the person from whom the defective copy came, who is required either to furnish another copy, or a satisfactory explanation. They are then arranged, paged, and inserted in books for reference.

Alphabetical indexes of births, deaths, and marriages are prepared and kept in the general register office; and any person, on payment of 1*s*., may search these indexes for any entry, and, on finding it, may, if he wish, obtain, for 2*s*. 6*d*., a stamped copy of such entry, which will be "received as evidence of the birth, death, or marriage to which the same relates, without any further or other proof of such entry." There are separate alphabetical indexes for the births, the deaths, and the marriages in each quarter. The registrar-general is bound to furnish, once a year, one of the principal secretaries of state with a *general abstract account* of the births, deaths, and marriages registered during the foregoing year, to be laid before parliament. Three reports of the registrar-general have already been published; and, in a statistical point of view, the sound, accurate, and judicious information which they embody, cannot be too highly appreciated. (*Statistics of the Brit. Empire.*)

RE'GISTRY OF DEEDS, in Law, exists in England only in certain districts; in the three ridings of Yorkshire, and in Middlesex, it is established by act of parliament. It does not extend to copyhold estates, or to leases not exceeding twenty-one years in possession. The intention of the registry was to give notice to purchasers of incumbrances existing on estates. But its value, in this respect, is materially lessened by the prevalence of the equitable doctrine of *notice;* namely, that where a party is, either actually or constructively, aware of incumbrances not registered, he is bound by such knowledge.

REGISTRY OF SHIPS. *See* SHIPS, REGISTRY OF.

RE'GIUM DONUM. (Lat. *royal gift.*) An annual grant of public money in aid of the maintenance of the Presbyterian clergy in Ireland. It was instituted by William III. in 1690, and remodelled in 1790. The stipends are paid to ministers both of the "Synod of Ulster" and "Seceding Synod," the two principal divisions of the sect.

REGIUS PROFESSORS. The name given to those professors in the English universities whose chairs were founded by Henry VIII. In the Scotch universities, in which the patronage of by far the greater number of chairs is vested in the civil bodies, those professors are called regius professors who have been appointed by the crown.

REGLET. (Lat. regula.) In Architecture. *See* FILLET.

REGRATING. *See* FORESTALLING.

REGRE'SSION. (Lat. regressus, *a going backwards.*) In Astronomy, the *regression of the moon's nodes* is the motion of the line of intersection of the orbit of the moon with the ecliptic, which is retrograde, or contrary to the order of the signs. This motion of the nodes of the lunar orbit takes place with considerable rapidity, the whole revolution being accomplished in about 18½ years. The nodes of the planetary orbits also regress on the ecliptic; but, in the case of the planets, the regression is extremely slow, that of the nodes of Mercury, which is the most rapid, amounting only to about 42 seconds of a degree in a solar year. *See* NODE, PLANET.

REGULAR BODIES. *See* PLATONIC BODIES.

REGULAR FIGURES, in Geometry, are equilateral and equiangular polygons. Circles can be described within and about such figures; but such figures can be described by geometrical methods only in particular cases. General expressions for the radii of the circles

described within and about them (r and R), and for their areas and angles, can, however, be given in neat forms. Thus, if n denote the number of sides of the polygon, and if u° represent the nth part of 180°, we shall have, a being the side, $R = \frac{1}{2} a \operatorname{cosec.} u^\circ$, $r = \frac{1}{2} a \cot. u^\circ$, area $= \frac{1}{4} n a^2 \cot. u^\circ$.

Tables of the values of cosec. u° and cot. u°, computed from these expressions, may be seen in most works on mensuration adapted to the values of n as far as 12. (See *Hutton's Mensuration.*)

RE'GULARS. In the Roman Catholic Church, those that profess and follow a certain rule of life, and observe the three vows of poverty, chastity, and obedience, are so called.

REGULA'TOR. In Machinery, a general name for any contrivance of which the object is to produce the uniform movement of machines. The regulators most commonly applied are the *fly* and the *governor*, for which see the respective terms.

The regulator of a watch is the spiral spring attached to the balance. This ingenious contrivance, the invention of Hooke, has contributed as much to the improvement of watches as the pendulum to the improvement of clocks.

In a paper published in the *Memoirs of the Royal Astronomical Society*, vol. xi., the present Astronomer Royal has investigated the mathematical problem of the motion of the regulator applied to the clock-work by which motion is given to large equatorial telescopes. For this purpose absolute uniformity of motion is of very great importance. The construction usually adopted, in this country at least, depends on the same principle as that of the governor of the steam-engine. Two balls suspended from the upper part of a vertical axis by rods of a certain length, are made to expand by the rotatory velocity of the axis; and when the expansion reaches a certain limit, a lever is pressed against some revolving part, whereby a friction is produced which immediately checks the velocity. Now the uniformity of the rotatory motion of the spindle depends upon the assumption, that if upon the whole the retarding forces are equal to the accelerating forces, the balls will move in a circle, and in no other curve. But this assumption is incorrect; for the balls may move in a curve differing insensibly from an ellipse; and, in some instances, Mr. Airy observed the balls to revolve in an ellipse of considerable eccentricity. When this takes place, the rotatory motion of the spindle becomes exceedingly variable. This injurious effect may be partly counteracted by constructing the apparatus so that the revolutions shall be either very slow or very quick; the former method has the effect of giving greater smoothness of motion, but the second insures more completely that the object observed shall remain steady in the field of the telescope.

RE'GULUS. In Chemistry. The old chemists designated several of the brittle or inferior metals by this term, when freed from impurities and obtained in their metallic state: it is thus that they speak of *regulus of antimony*, *of bismuth*, &c.

REHABILITA'TION, in Foreign Criminal Law, is the reinstatement of a criminal in his personal rights which he has lost by a judicial sentence. Thus, in Scotland, a pardon from the king is said to rehabilitate a witness labouring under *infamia juris*. In France, persons condemned to imprisonment or compulsory labour may demand their rehabilitation five years after the expiration of their penalty: the demand is considered by the cour royale of the district, and pronounced upon by the king in his privy council. Various singular forms were attached to the process of rehabilitation in ancient times. There are extant letters of Charles VI. given in 1383, permitting a criminal whose hand had been cut off for homicide to replace it by another made in such fashion as he may choose.

REHEA'RSAL. The recital in private of an opera, oratoria, or, in short, any dramatic work, previously to public exhibition.

REIN-DEER. (Germ. rennthier.) *Cervus tarandus*, Linn. A large species of *Cervus* with branched, recurved, round antlers, the summits of which are palmated. These antlers are remarkable for the size of the branch which comes off near the base, and is directed forwards, called the brow-antler, and which is said to be used by the animal to clear away the snow from the hidden lichens which constitute the food of the rein-deer during the long and severe winter of Greenland, their native clime. As the female also possesses antlers of similar form, but smaller upon the whole than those of the male, their function as instruments to obtain food is rendered more probable, since in the deer which do not exist in arctic climes the females are destitute of antlers. These appendages of the rein-deer are annually shed and renewed in both sexes.

The length of a full-grown male is about nine feet, that of the head is fifteen inches. They are well clothed with hair, which becomes thicker, longer, and of a whiter colour in the winter season; at which time the male has a white beard, like the goat. The rutting season is at the beginning of winter, and the hind brings forth one, rarely two calves, in May or June.

The rein-deer is swift of foot, sharp-sighted, has an acute smell and hearing. It is more cautious and timid in herds than when solitary. It can swim well, and often crosses lakes and rivers.

The flesh of the rein-deer, which is held in great esteem by the Greenlanders, is usually eaten raw, or dried with the smoke of the *lichen nivalis*. The blood is boiled with berries mixed with the fat, which is also preserved separately and used as lard. The half-digested contents of the paunch of the rein-deer is the Greenlander's prime luxury; nor is the trail rejected. The hide of the rein-deer supplies the Greenlander with a beautiful material for his tent, his clothing, his bedding. The bones and antlers are worked into implements for domestic use, for fishing and hunting. The tendons are split into threads.

The Greenlanders likewise use the spare hides of the rein-deer as an article of barter.

REI'NECKE (The Fox). The name of a celebrated popular German epic poem, which, during the latter part of the middle ages and the early centuries of modern times, enjoyed an almost European reputation. It became first known through the medium of a Low German version in the 15th century; and it has, with few interruptions, ever since involved the German literati in discussions as to its origin, which are yet apparently far from being settled. It contains a humorous and satirical account of the adventures of Reinecke (the fox) at the court of King Nodel (the lion); exhibits the cunning of the former, and the means which he adopted to rebut the charges preferred against him, and the hypocrisy and lies by which he contrived to gain the favour of his sovereign, who loaded him with honours. The king, the officers of his court, and all his subjects are represented, as in *Æsop's Fables*, under the names of the animals best suited to their respective characters; and the poem is an admirable satire on the intrigues practised at a weak court. The most successful versions of this poem are those of Goethe, in hexameters; of Soltau, in the measure of the original; and the more recent attempt of Ortlepp. This poem appears, in some form or other, to have been known throughout Europe. For full information respecting it, the reader may consult Meon (*Roman du Renard*, Paris, 1826); and the *Reinhart Fuchs*, by Jacob Grimm (Berlin, 1834).

REINFO'RCE, in Artillery, is that part of a gun nearest to the breech, made stronger to resist the explosive force of the powder. *See* GUN.

REINFORCE RINGS, are flat hooplike mouldings on the reinforces on the side nearest the breech. There are usually two, the second being rather smaller than the first.

REIS-EFFENDI. The name given to one of the chief Turkish officers of state. He is chancellor of the empire and minister of foreign affairs, in which capacity he negotiates with the ambassadors and interpreters of foreign nations.

REITERS. (Germ. reuters, *riders*.) The German cavalry of the 14th and 15th centuries were so called; especially in France during the religious wars, in which they served on the Protestant side. At that period they were light-armed, and carried a long sword and carbine.

REJOI'NDER. In Law, the fourth stage in the pleadings in an action, being the defendant's answer to the plaintiff's replication. The next allegation of the plaintiff is called *surrejoinder*. *See* PLEADING.

RELAIS. In Fortification, a narrow walk of four or five feet wide, left without the rampart to receive the earth which may be washed down and prevent its falling into the ditch. It is sometimes for greater security pallisaded.

RELA'PSE (Lat. relabor, *I fall back*), is applied, in Ecclesiastical Law, to a heretic who falls back into an error which he has abjured.

RELATION, INHARMONIC. In Music, a term denoting that a dissonant sound is introduced which was not heard in the preceding chord.

RELE'ASE (Fr. relaisser), in Law, signifies, properly speaking, a discharge of a right: *e. g.* 1. A release of land is a discharge or conveyance of a man's right in lands and tenements to another that has some former estate in possession, on which principle the common mode of conveyance by lease and release is founded; *i. e.* releasing all the right of the releasor to a party already in possession under a lease for a year. 2. A release of a right of action; which may be pleaded in bar. (*See* PLEADING.) A release "of all demands" discharges all sorts of actions, rights, titles, conditions, executions, appeals, covenants, contracts, annuities, rents, recognizances, &c.

RE'LICS (Lat. reliquæ), in the Romish Church, are the remains of saints and holy men, or of their garments, &c., which are enjoined to be held in veneration, and are considered in many instances to be endued with miraculous powers. They are preserved in the churches, to which they are often the means of attracting pilgrimages,

and in very ignorant times and places have been actually made objects of adoration. The virtues which are attributed to them are defended by such instances from scripture as that of the miracles that were wrought by the bones of Elisha. (2 Kings, xiii. 21.)

RELIE'F, in Feudal Law, is derived from the Latin relevare, *to take up;* because the tenant, by payment of the relief, was said to take up the fief which had fallen to the lord by the death, &c. of his predecessor. "The heir," says Blackstone, "when admitted to the feud which his ancestor possessed, used generally to pay a fine or acknowledgment to the lord in horses, arms, money, or the like, for such renewal of the feud; which was called a relief, because it raised up and re-established the inheritance, or, in the words of the feudal writers, 'incertam et caducam hæreditatem relevabat.'" Reliefs, together with the other incidents of feudal tenure, were abolished in England by stat. 12 Car. 2. *See* FEUDAL SYSTEM.

RELIEF. In Architecture, the projection of a figure or ornament from the ground or plane on which it is sculptured. In Sculpture, when the whole of the figure stands out, the work is denominated *alto-rilievo;* when only half out, *demi-rilievo;* and when its projection is very small, it is called *basso-rilievo.*

RELIEF, *Rilievo.* In Sculpture, that species of sculpture in which the figures are engaged on or rise from a ground. There are three sorts of *rilievo*, — *basso-rilievo*, in which the figures or other objects have but small projection from the ground on which they are sculptured; *mezzo-rilievo*, in which the figures stand out about half their natural proportions, the other half appearing immersed in the ground; and, lastly, *alto-rilievo*, in which the figures stand completely out from the ground, being attached to it only in a few places, and in others worked entirely round like single statues; such are the metopæ of the Elgin marbles in the British Museum, which marbles also in the Panathenaic procession exhibit some exquisite examples of basso-rilievo.

RELIEF SYNOD. A respectable body of Presbyterian dissenters in Scotland, whose ground of separation from the established church was the violent exercise of lay-patronage which obtained in the latter. Though patronage, or the appointment of clergymen to church benefices by presentations, had been established by act of parliament in 1712, yet a minority of the clergy were opposed to that measure; at least to the intrusion of a minister into a parochial charge contrary to the sentiments of the people. The majority of the church, however, entertained different views, and rigorously enforced the provisions of the act of 1712. With this state of things the people generally, but particularly in rural districts, were dissatisfied; and hence the origin of the Secession church, and the Relief. *See* BURGHERS.

The origin of the Relief may be dated in 1752. Six of the ministers of the Presbytery of Dunfermline having refused, contrary to the express authority of the General Assembly of the Church of Scotland, to assist at the admission of Mr. Richardson to the parish of Inverkeithing (the people being unwilling to receive him as their pastor), were summoned before this venerable court for contumacy. They pleaded conscientious scruples; but this representation had no effect on the assembly; and, as an example to the church, one of the six recusants was peremptorily deposed from the office of the ministry, while the remaining five were suspended. Mr. Gillespie, minister of Carnock, the individual deposed, still claimed his pastoral relation to his flock; and though deprived of the use of the parish church, preached in the fields, attended not merely by his former hearers, but by many others attracted by the peculiar circumstances of the case. A chapel was afterwards built for him in the neighbouring town of Dunfermline, where he continued to preach till his death, and to oppose the law of patronage in the church. Mr. Gillespie for a few years stood alone; but in consequence of the violent settlement of a clergyman in the town of Jedburgh, the great body of the people of that place, forsaking the established church, gave a call (1759) to Mr. Thomas Boston, minister of a neighbouring parish, to be their pastor. Mr. Boston, for whom they erected a chapel, accepted the invitation, and withdrew from the church of Scotland. Owing to exactly similar circumstances, the people of the parish of Kilconquhar, in Fifeshire, followed the example set them in Jedburgh, and chose Mr. Collier to be their minister. On the 22d of November, 1759, Mr. Gillespie and Mr. Boston, with a lay elder from each of their congregations, met in a presbyterian capacity at Colinsburgh, in the last-mentioned parish, to induct Mr. Collier to his charge. On the evening of the same day these three ministers met, and agreed to form themselves into an ecclesiastical body, to be called the "Presbytery of Relief, for the relief of Christians oppressed in their Christian privileges." This sect gradually gained accession to their number from causes similar to those which we have already detailed, and at length formed themselves into a synod, which, at this date (1842), embraces eleven presbyteries, including 116 congregations; being, in point of numbers and influence, the third ecclesiastical body in Scotland. The founders of the Relief professed to differ from the established church on no point other than the right of patrons to appoint ministers against the inclinations of the people. This still constitutes the leading characteristic of the sect; but on this they have engrafted voluntary church principles, or are hostile to the principle of a national church, or to state endowments of religion. The Secession and Relief are at present engaged in considering overtures made mutually to each other for forming a union of the two denominations. The Relief Synod have a professor of divinity in their own connection. (*Smith's Hist. Sketches of the Relief Church; Hutchison's Compendious View of the Synod of Relief; Adam's Relig. World Displayed*, vol. iii. p. 223—32.; *M'Kerrow's Hist. of Secession*, v. i. p. 319—24. 326—28.)

RELIE'VING TACKLES. Temporary tackles attached to the end of the tiller in bad weather to assist the helmsman, and in case of accident happening to the tiller ropes. They are also strong tackles from the wharf, to which the ship is hove down, passed under her bottom and attached to the opposite side, to assist in righting her afterwards, as well as to prevent her from oversetting entirely.

RE'LIQUARY. A receptacle for the relics venerated in Roman Catholic churches. The difference between a *reliquary* and a *case* (Fr. châsse) used for the same purpose is, that the former is smaller in dimensions, and contains only small fragments; the latter in many instances entire bodies.

REMAI'NDER. The difference of two quantities left after the less is subtracted from the greater.

REMAINDER. A *remainder*, in Law, is a future estate in lands, tenements, or hereditaments, limited to arise after the determination of another estate; as if land be granted to A. for twenty years, and afterwards to B. and his heirs for ever, B. has a remainder in fee. An estate in reversion is the residue left in the grantor, to commence in possession after the determination of some particular estate granted out by him; as if A. being seised in fee-simple, gives to B. and his heirs male of his body (thus creating an estate tail), on the failure of such heirs male the land given reverts to A., who, therefore, prior to such failure, has an estate in reversion in the lands. Remainders are either *vested*, or *contingent;* vested or *executed*, where the estate is invariably fixed, to remain to a determinate person after the preceding estate (called the *particular* estate) is spent. In this case, the remainder man has a present interest, to be enjoyed *in futuro*. Contingent remainders, otherwise called *executory*, are defined to be "where the estate in remainder is limited to take effect either to an uncertain person, or upon an uncertain event; so that the particular estate may chance to be determined, and the remainder never take effect." The doctrines of law with reference to these estates have gradually been moulded into a system so intricate, and replete with the most refined distinctions, that it would be impossible to give a cursory view of this branch of our jurisprudence. An instance of a vested remainder is to be found in the example before cited of an estate granted to one party for a term of years, and afterwards to another in fee-simple. A contingent remainder limited to an uncertain *person* is where, for instance, there is an estate to A. for life, and afterwards to B.'s eldest son (then unborn). And in order to prevent the accumulation of future possible estates, the rule of law is, that no limitation by way of remainder or executory devise (*i. e.* a grant of a contingent remainder by will) shall be good which is to take effect after the determination of a life or lives in being and 21 years (the period of minority) afterwards. An instance of a contingent remainder limited on an uncertain event is where land is given to A. for life, and in case B. survives A. then to B. in fee.

The particular estate, which precedes (in legal language *supports*) a vested remainder, may be either of years, or of freehold: to support a contingent remainder it must necessarily be of freehold.

REMBLAI. (Fr.) A term used in Fortification to denote the earth or materials used in filling up a trench or excavation. It is opposed to *deblai*, which denotes the materials excavated.

REMEMBRANCERS. Officers of the Court of Exchequer, who perform various functions, the chief of which is to put the judges of that court in remembrance of such things as are to be called on or done for the king's benefit. They were formerly three in number, — the king's remembrancer, the lord treasurer's remembrancer, and the remembrancer of first fruits; but the duties of the second of these officers were merged in the first by 3 & 4 Will. 4. c. 99.

RE'MIGES. (Lat. remigo, *I row.*) The quill feathers of the wings of a bird, which, like oars, propel it through the air.

RE'MIPEDS, *Remipedes.* (Lat. rema, *an oar;* pes, *a foot.*) The name of an order of Coleopterous insects, in-

cluding those which have tarsi adapted for swimming. *See* NECTOPODS.

REMI'TTENT FEVER. Any fever which suffers a decided remission in its violence during the twenty-four hours, but without entirely leaving the patient, is called a *remittent;* it differs from an intermittent in there never being a total absence of fever. These fevers are most common in autumn, and they vary in degree from extreme mildness to alarming violence, and are both inflammatory and malignant. The remittent fever of children, or, as it is often called, the *infantile fever*, is generally symptomatic either of worms in the intestines, or of a foul state of bowels, arising from inattention to diet, or from the indigestible trash which children frequently indulge in: the tongue is very foul, the head aches, the belly is tumid, food is loathed; the child is drowsy all day, but restless and often delirious at night, and the bowels torpid. A proper system of purging is the most essential part of the treatment in these cases; and under it the symptoms, though often alarming and obstinate, gradually give way. Calomel, with scammony and jalap, aided, if necessary, by infusion of senna and aperient salts, are the principal remedies, and saline draughts and diluents in the intervals. If bilious diarrhœa ensue, with vomiting, the irritability of the stomach must be allayed by effervescing salines, and that of the bowels by very mild aperients; if the head is much affected, cold and evaporating lotions may be used. Good air, thorough ventilation, and light farinaceous diet, with the above treatment, generally effect a cure; but the disorder is often very obstinate, and continues for three weeks or a month. The *yellow fever*, or bilious remittent of hot climates, and especially of the West Indies, is another form of this fever: it appears to be produced by marsh miasma. In all these fevers particular symptoms occasionally present themselves, which require particular modes of treatment; and this must also be modified according to the inflammatory, malignant, nervous, or intermittent form which they may assume or pass into.

REMONSTRANTS. In Ecclesiastical History. *See* ARMINIANS.

RE'MPHAN. An idol worshipped by the Israelites while in the wilderness, according to the language of St. Stephen as recorded in the Acts, "Ye took up the tabernacle of Moloch, and the star of your god Remphan." In this passage commentators are agreed that St. Stephen quotes the words of Amos, "Ye have borne the tabernacle of your Moloch and Chiun, your images." Chiun and Remphan are therefore the same, and both are thought to be personifications of Sirius, the Dog-star. (*Enc. Brit.*) Chiun is supposed by some to be the same word as Chan or Khan, Chagan, König, "king"; Remphan or Raiphan, "high or exalted light."

RENAL GLANDS. There is a glandular body upon each kidney of a somewhat triangular shape, small in the adult, but in the fœtus longer than the kidney; it is called the renal, or supra-renal, gland or capsule: it has no excretory duct, and its use is unknown.

RENDERED. In Architecture. *See* RENDERED AND SET.

RENDERED AND FLOATED. In Architecture, plastering of three coats on brickwork.

RENDERED AND SET. In Architecture, a term used to denote plastering of two coats on naked brick or stone work. If the work is to be of three coats, it is called *roughing in*. *Pricking up* is the first of three-coat plaster on lath, or on brickwork, that has been previously rendered. The materials for rendering and pricking up are the same.

RENDERED, FLOATED, AND SET FOR PAPER. In Architecture, plastering of three coats; the first being lime and hair upon brickwork; the second, the same compound, with the addition of a little more hair, and then *floated* with a long rule; the third, *fine stuff* mixed with white hair.

RENNET, or RUNNET. The prepared inner membrane of the calf's stomach, which has the property of coagulating the albumen of milk and converting it into *curd and whey*.

RENT. (Lat. reditus; Fr. fermage, loyer des terres.) In Political Economy, and in ordinary language, the sum paid by the farmers or lessees of lands to the landlords.

In order to acquire clear and correct ideas with respect to the nature and origin of rent, it is necessary to discriminate between the sources whence it usually arises; that is, between the portion paid for the use of the natural and inherent powers of the soil, and the portion paid for the use of the buildings, fences, drains, roads, and other improvements made upon the soil. Two farms may be naturally of about equal goodness, and equally well situated; but if little or no capital have been laid out on the one, while a great deal has been judiciously laid out on the other, they will let for very different sums. It is usual, no doubt, to class all sums derived from land, whatever may be their origin, under the common name of rent; but it is obviously necessary, in an inquiry of this sort, to distinguish between the sums paid for the use of the land, and those paid for the use of the improvements, if there be any, made upon it. Landlords are, for the most part, capitalists as well as owners of the soil; and the sums paid to them by their tenants for the use of the capital expended upon the soil, though included under the term rent, are substantially and in fact profits, and depend wholly on the circumstances by which they are governed. *Rent really, therefore, consists of that portion of the gross sum paid for land, that is, paid for the use of the natural and inherent powers of the soil, or that would be paid for the land supposing it to be in a state of nature, and without any improvement upon it.* The owners of the soil receive this portion of their gross income not because they are capitalists, but because they are landlords. And we shall now briefly endeavour to exhibit the origin of this payment, or of rent, in the scientific and restricted sense of the term.

Origin of Rent.— On the first settling of any country abounding in large tracts of unappropriated land, rent, in the sense now explained, is unknown; and for this obvious reason, that no person will pay rent for what may be procured in unlimited quantities for nothing. In such countries, rent only begins to appear when the best of the unappropriated lands have become private property, and been occupied. Suppose, however, this comes to be the case; and that the population has increased, so that the demand for raw produce can no longer be supplied by the culture of the best lands: under these circumstances, it is plain either that population must become stationary, or that the price of raw produce must rise so as to enable inferior lands to be cultivated. No advance short of this will procure another bushel of corn; and competition will not, as will be immediately seen, allow prices to rise permanently above this level. Under the circumstances supposed, the inhabitants have but one alternative. If they pay a price sufficient to cover the expense of cultivating secondary lands, they will obtain additional supplies; if they do not, they must be without them.

Suppose, now, that the price rises so as to pay the expense of raising corn on soils which, in return for the same expenditure that would produce 100 quarters on lands of the first quality, will only yield 90 quarters; it is plain it will then be indifferent to a farmer whether he pay a rent of ten quarters for the first quality of land, or farm the second quality, which is unappropriated and open, without paying any rent. If the population went on increasing, lands which would yield only 80, 70, 60, 50, &c. quarters in return for the same expenditure that had raised 100 quarters on the best lands, might be successively brought under cultivation. And when recourse has been had to these inferior lands, the corn rent of those that are superior would plainly be equal to the difference between the quantity of produce obtained from them and the quantity obtained from the worst quality under tillage. Suppose, for example, that the worst quality cultivated yields 60 quarters, then the rent of the first quality will be 40 quarters, or 100 — 60; the rent of the second quality will, in like manner, be equal to the difference between 90 and 60, or 30 quarters; the rent of the third quality will be equal to 80 — 60, or 20 quarters, and so on; the produce raised on the land last cultivated, or by means of the capital last applied to the soil, being all the while sold at its necessary price, or at that price which is sufficient merely to cover the cost of its production, including therein the ordinary rate of profit on the capital of the cultivators. If the price were above this level, agriculture would be a peculiarly profitable business, and tillage would be immediately extended: if, on the other hand, the price fell below this level, capital would be withdrawn from the soil, and the poorer lands thrown out of cultivation. Under such circumstances, it is clear that rent could not enter into the price of that portion of the necessary supply of produce raised by means of the capital last applied to the soil. Its price is exclusively made up of wages and profits. The proprietors of the superior lands obtain rent; but this is the necessary result of their greater fertility. The demand cannot be supplied without cultivating inferior soils, the produce of which must necessarily sell for such a price as will afford the ordinary rate of profit to their cultivators. This price will, however, yield a surplus over and above the ordinary rate of profit to the cultivators of the more fertile lands; and it *is this surplus that forms rent.*

In so far, therefore, as rent is a return for the use of the soil, and not for the capital laid out on improvements, it results entirely from the necessity of resorting, as population increases, to soils of a decreasing degree of fertility, or of applying capital to the old land with a less return. It varies inversely as the produce obtained by means of the capital and labour employed in cultivation; increasing when the profits of agricultural labour diminish, and diminishing when they increase. Profits are at their maximum in countries like Australia, Indiana, and Illinois; and generally in all situations in

which no rent is paid, and the best of the good lands only are cultivated; but it cannot be said that rents have attained their maximum so long as capital yields any surplus in the shape of profit.

A quarter of wheat may be raised in Kent or Essex, or in the Carse of Gowrie, for a *fourth* or a *fifth* part, perhaps, of the expense necessary to raise it on the worst soils in cultivation in the less fertile parts of the country. The same article cannot, however, have two or more prices at the same time and in the same market. And it is plain that if the price be not such as will indemnify the producers of the wheat raised on the worst soils, they will cease bringing it to market, and the required supplies will no longer be obtained; while, if the price exceed this sum, fresh capital will be applied to its production, and competition will soon sink prices to their natural level — that is, to such a sum as will afford the common and ordinary rate of profit to the raisers of that portion of the required supply which is produced under the most unfavourable circumstances, or at the greatest expense. The cost of producing this portion governs the price of the whole crop. It is plainly, therefore, the same thing to the consumers whether, in an advanced stage of society, the excess of return over the cost of production on superior lands belong to a non-resident landlord or an occupier. It must belong to the one or the other. Corn is not high because rent is paid, but rent is paid because corn is high; because the demand is such, that it cannot be supplied without cultivating soils of a diminished degree of fertility as compared with the best. Suppose there is in any country an effectual demand for ten millions of quarters of corn; that nine millions may be raised upon lands that yield a high rent; but that it is necessary to raise the other million on inferior lands, which yield nothing but the common and average rate of profit to their cultivators. Under these circumstances, it is clear that the relinquishing of the rents payable by the cultivators of the superior lands would be no boon to the cultivators of those that are inferior. It would not lessen their expenses; that is, it would not lessen the capital and labour employed by them in the production of that portion of the required supply raised on their lands; and unless it did this, it is obviously impossible, supposing the demand not to decline, that it could lower prices. Although, therefore, landlords were to give up the whole of the rents, their doing so would have no influence over prices. Such an act would turn farmers into landlords, and landlords into beggars; but there its effect would stop. But the case is entirely different when the cost of production varies. If it diminish, the competition of the producers will infallibly sink prices in the same proportion. If it increase, no supplies will be brought to market, unless the price rise to a corresponding level. In no case, therefore, whether the demand be great or small, whether it be for one thousand or one million quarters, can the price of raw produce ever permanently exceed or fall below the sum necessary to pay the cost of producing that portion of the required supply that is raised on the worst land, or by means of the last capital laid out on the soil.

It has been objected to this theory, that though it may apply in unappropriated countries like New Holland, it will not apply in countries like England, where land is universally appropriated, and where, it is alleged, the worst qualities always yield some small rent to the proprietor.

It may be observed of this objection, that even if it were well founded it would not practically affect the conclusions previously established. There are in England and Scotland vast tracts of land which do not let for 6*d*. an acre; but to cultivate them would require an outlay of many thousands of pounds, and the rent would consequently bear so small a proportion to the expenses of production as to become altogether evanescent and inappreciable.

There can be no doubt, however, that there is in this, and most other extensive countries, a great deal of land which yields no rent. In the United States and Russia, such is unquestionably the case; and yet no one presumes the to say, that laws which govern rent in them are different from those which govern it in England and France. The poorest lands are always let in immense tracts. If it were attempted to let particular portions of these tracts separately, no one would offer for them; but they appear to yield rent, because, though they really fetch nothing, the more fertile spots with which they are intermixed may, in most cases, be let for a larger or smaller rent. But though every rood of land in Britain paid a high rent, it might still be truly affirmed that such rent did not enter into the price of raw produce. The rent of a country consists of the difference, or the value of the difference, between the produce obtained through the agency of the capital first applied to the land and that which is last applied to it. It would, as already seen, be exactly the same thing to a cultivator, whether he paid a rent of ten quarters to a landlord for land yielding, with a certain outlay, 100 quarters of corn, or employed the same capital in cultivating inferior land yielding only 90 quarters for which he paid no rent. Were it possible always to go on obtaining equal returns for every equal additional capital applied to the superior soils, no person, it is obvious, would ever resort to those of inferior fertility; and, under such circumstances, the largest population might be supported on the smallest extent of land. But, such is not the law under which food is obtained; and the fact, that in the progress of society new and less fertile land is invariably brought under cultivation, demonstrates that additional capital and labour cannot be indefinitely applied with the same advantage to the old land. The state of a country may be such, the demand for agricultural produce may be so great, that every quality of land yields rent; but it is the same thing, in respect of this theory, if there be any capital employed on land which yields only the ordinary rate of profit, whether it be employed on old or new land. And that there is every where a very large amount of capital employed in such a manner, is a fact of which there cannot be any doubt whatever. The owners and occupiers of land are influenced by the same principles in the employment of their capital and labour that influence other men. Like them, they endeavour, in prosecuting their own interest, so to adjust the capital they employ that the last quantity laid out may yield the common and ordinary rate of profit, neither more nor less. Suppose, for example, that a landlord occupies a farm which he might let for 200*l*. a year, producing, with a certain outlay of capital, 300 quarters of wheat. If the farm be managed with the requisite skill and attention, the wheat should, at an average, sell for so much money as is equivalent to the rent, the expense of labour, and the profit on the capital employed. Suppose, now, that the landlord finds that by laying out additional capital on the farm it may be made to yield 10, 20, 50, or 100 quarters more, he will make the outlay, provided the additional produce yield the ordinary rate of profit. He will not wait, before commencing the improvement, until prizes rise to a still higher elevation. It will be quite enough to induce him immediately to set about it, that they are such as afford a fair prospect of realizing the usual return on the capital to be expended. He will, in fact, act exactly as the merchant or manufacturer acts who sends another ship to sea, or builds another cotton mill, whenever he supposes that the capital so embarked will yield customary profits. And supposing that the farm is let to a tenant, he, it is obvious, will do the very same thing as the proprietor, if he obtain so much more profit as will, over and above the usual return, suffice to replace the capital itself previously to the termination of his lease. Whether he will employ this additional capital depends entirely on the circumstance of prices being such as will repay his expenses and profits; for he knows he will have no additional rent to pay. Even at the expiration of his lease, the fact of an additional capital having been employed would not occasion any rise of rent, unless in so far as some portion of it, by being permanently incorporated with the soil, may increase its productive powers; and were his landlord to require more rent because a greater moveable capital had been employed, he would cease to employ it, since by the supposition he gets only the same profit he might get by employing it in any other department of industry.

If we reverse the previous suppositions, and suppose that the owner of a farm finds that, owing to a fall in the price of corn, the capital employed in its cultivation does not yield the common and ordinary rate of profit, he will then, acting on the same principle that led him in the other case to increase the capital on the farm, withdraw a part, or it may be the whole of such capital: and supposing it to be let, the rent would be proportionally reduced at the end of the lease, or sooner.

It is not to be supposed that we mean to affirm that these results follow immediately, and without any difficulty, on a rise or fall of prices; on the contrary, they take place only by degrees; and are often productive, on the one hand, of peculiar advantages, and, on the other, of peculiar sacrifices. But, in purely theoretical inquiries, or such as have the establishment of principles for their object, such accidental circumstances may be overlooked; and it may, generally speaking, be said that the last portion of capital laid out on the soil yields only the common and average rate of profit. If, on the one hand, it were to yield *more*, fresh capital would be drawn to agriculture, and competition would sink prices to such a level that they would only yield this rate. If, on the other hand, the capital last applied to the soil should yield *less* than this common and average rate, it would be withdrawn, until, by the rise of price, the last remaining portion of capital left this rate to its owners: and hence it follows, that whether the last quality of land taken into cultivation yield rent or not, the last capital applied to the land yields only the common and average rate of profit; and, consequently, the price of the produce which it yields, and which determines the price of all the rest, is totally unaffected by rent.

It is farther said by those who have cavilled at this

theory, that it represents the cultivation of bad land as the cause of rent; whereas it is, they affirm, the growing demand of the population for food that is its cause, it being the rise of price consequent upon this increased demand that occasions the cultivation of bad lands, and the payment of a rent for those that are superior. This, however, is at best mere verbal trifling. The demand of the population for corn elevates its price to such a height as is necessary to obtain the required supply, and may, therefore, be truly said to be the cause of its being produced; but rent originates in the peculiar circumstances under which supplies of corn are produced. Were it not that it is most frequently necessary, in obtaining increased supplies of corn, to resort to soils of different degrees of fertility, or to apply capital, with a less return, to the old land, rent would be altogether unknown; nor, though the demand for corn were increased in a tenfold proportion, would prices be permanently elevated. It does, therefore, seem to be logically, as well as substantially correct, to affirm that the decreasing fertility of the soil is the immediate cause of rent, and that its amount is determined by the extent to which bad land is cultivated or good land forced.

This analysis of the nature and causes of rent discovers an important distinction between agricultural, and commercial, and manufacturing industry. In manufactures, the worst machinery is first set in motion, and every day its powers are improved by new inventions, and it is rendered capable of yielding a greater amount of produce with the same expense; and as no limits can be assigned to the quantity of improved machinery that may be introduced, as a million of steam engines may be constructed for the same, or rather for a less proportional expense than is required for the construction of one, competition never fails to reduce the price of manufactured commodities to the sum for which they may be purchased, according to the least expensive method of production.

In agriculture, on the contrary, the best machines, or best soils, are brought first into use; and recourse is afterwards had to inferior soils, or those requiring a greater expenditure to make them yield the same supplies. It is true that improvements in the construction of farming implements, the discovery of more efficient manures, and the introduction of more prolific crops and improved systems of management, increase in a high degree the productiveness of the soil, and proportionally reduce the price of raw produce; but a fall of price, though permanent in manufactures, is only temporary in agriculture. When the price of corn is reduced, all classes obtain greater quantities than before in exchange for their products, or their labour; hence the rate of profit, and consequently the accumulation of capital, are both increased; and this increase, by causing a greater demand for labour and higher wages, leads, in the end, to an increase of population, and a further demand for raw produce and an extended cultivation. Agricultural improvements obviate, sometimes for a lengthened period, the necessity of having recourse to inferior soils; still, however, this effect cannot be permanent. The stimulus which they at the same time give to population, and the natural tendency of mankind to increase up to the means of subsistence, is sure, in the long run, to raise prices, and, by forcing recourse to poor lands, rents also.

In illustrating this important distinction between agriculture and manufacturing industry, Mr. Malthus has set the theory of rent in a striking point of view. "The earth," he observes, "has been sometimes compared to a vast machine, presented by nature to man for the production of food and raw materials; but to make the resemblance more just, as far as they admit of comparison, we should consider the soil as a present to man of a great number of machines, all susceptible of continued improvement by the application of capital to them, but yet of very different original qualities and powers.

"This great inequality in the powers of the machinery employed in procuring raw produce, forms one of the most remarkable features which distinguishes the machinery of the land from the machinery employed in manufactures.

"When a machine in manufactures is invented which will produce more finished work with less labour and capital than before, if there be no patent, or as soon as the patent is over, a sufficient number of such machines may be made to supply the whole demand, and to supersede entirely the use of all the old machinery. The natural consequence is that the price is reduced to the price of production from the best machinery; and if the price were to be depressed lower, the whole of the commodity would be withdrawn from the market.

"The machines which produce corn and raw materials, on the contrary, are the gifts of nature, not the works of man; and we find by experience that these gifts have very different qualities and powers. The most fertile lands of a country, those which, like the best machinery in manufactures, yield the greatest products with the least labour and capital, are never found sufficient to supply the effective demand of an increasing population. The price of raw produce, therefore, naturally rises till it becomes sufficiently high to pay the cost of raising it with inferior machines and by a more expensive process; and, as there cannot be two prices for corn of the same quality, all the other machines, the working of which requires less capital compared with the produce, must yield rents in proportion to their goodness.

"Every extensive country may thus be considered as possessing a gradation of machines for the production of corn and raw materials, including in this gradation not only all the various qualities of poor land, of which a very large territory has generally an abundance, but the inferior machinery which may be said to be employed when good land is further and further forced for additional produce. As the price of raw produce continues to rise, these inferior machines are successively called into action; and as the price of raw produce continues to fall, they are successively thrown out of action. The illustration here used serves to show at once the necessity of the actual price of corn to the actual produce, and the different effect which would attend a great reduction in the price of any particular manufacture and a great reduction in the price of raw produce." (*Inquiry into the Nature and Progress of Rent*, p. 37.)

It appears, therefore, that in the earlier stages of society, and when only the best lands are cultivated, rent is unknown. The landlords, as such, do not begin to share in the produce of the soil until it becomes necessary to cultivate lands of an inferior degree of fertility, or to apply capital to the superior lands with a diminished return. Whenever this is the case, rent begins to be paid; and it continues to increase according as cultivation is extended over poorer soils, and diminishes according as these poorer soils are thrown out of cultivation. Rent, therefore, depends exclusively on the extension of tillage. It is high where tillage is widely extended over inferior lands, and low where it is confined to the superior descriptions only. But in no case does rent enter into price; for the produce raised on the poorest lands of a country, or by means of the capital last applied to the culture of the soil, determines the price of the entire crop; and this produce yields only the common and average rate of profit.

Influence of Situation on Rent.—In the previous statements we have, to simplify the consideration of the question, omitted to notice the influence of situation on rent. It is plain, however, that this is a very important element in determining its amount; and that difference of situation has precisely the same sort of influence over rent as differences of fertility. Thus, suppose two farmers employ equal quantities of capital, as 5000 quarters each, in the cultivation of farms of the same goodness,—the one situated in the immediate vicinity of London, and the other in Yorkshire; and suppose, farther, that London is the market to which the produce of both farms is sent, and that the cost of conveying corn from Yorkshire to London is 5*s.* a quarter: under these circumstances, if the gross produce of each farm were 1000 quarters, of which the landlord received one fifth part, or 200 quarters, as rent, the farm near London would fetch 50*l.* a year more than the farm in Yorkshire. For, as the corn raised in the districts adjacent to London is not adequate for its supply, its price in the city must suffice to pay those who bring any portion of the necessary supplies from the greatest distance, as well for the expenses of carriage as for those of production; and the farmer in the immediate vicinity, who gets this increased price for his produce, will have to pay a proportional increase of rent, in the same way that the occupierof good land has to pay an increased rent; when inferior lands are taken into cultivation.

It would, on many accounts, be desirable readily to distinguish between that portion of the gross rental of a country which is to be considered as rent, properly so called, or as the remuneration paid to the landlords for the use of the natural powers of the soil, and that portion which is the return to or the interest upon the capital laid out upon houses, fences, drains, roads, and other improvements. But how desirable soever, it is admitted by all practical men that it is quite impossible to make such a distinction with any thing approaching to accuracy. No two of the most expert agriculturists, supposing them to be desired to resolve the gross rental of a single improved farm into its constituent parts, would arrive at the same result. Improvements become so much blended with the natural powers of the soil, that the influence of the one cannot be separated from that of the other; and it is merely the joint value of the two that can be estimated. No doubt can, however, be entertained by any one who reflects for a moment on the vast sums, the many hundreds, or rather thousands of millions, that have been laid out upon the soil of Great Britain, that the payment made to the landlords for the use of its natural powers is inconsiderable, compared with that made to them on account of improvements;

3 X 2

and hence the inequality and mischievous operation of taxes on rent. Two landlords receive equal rents from their estates; but the rent of one is principally a consequence of natural fertility, while that of the other is derived principally from outlays of capital. What, then, could be more unfair than to subject them both to the same equal tax? And yet the amount of their rents is the only criterion to which recourse could be had in fixing the amount of the tax; for all the tax collectors in the world could not separate between what was really rent, in the scientific sense of the term, and what was interest on capital. Such a tax would oppose the most effectual obstacle to improvements. Instead of carrying capital from other employments to the land, it would henceforth be carried from the land to them. The object would not then be to have an estate look well, but to have it look ill; and it may be said of estates as of individuals,

Pauper videri Cinna vult, et est pauper.

The effects that were formerly produced by the *taille*, and that are now produced by the *contribution foncière* in France, and the fluctuating land taxes imposed in other countries, abundantly confirm the truth of this statement. Their influence has been most disastrous.

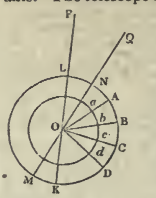
The theory of rent explained in this article was first promulgated and satisfactorily established in a tract on the corn laws, published at Edinburgh in 1777, by Dr. James Anderson, a native of Hermandston in Mid Lothian, editor of the *Bee* and other publications. But notwithstanding the clear and able manner in which he explained the theory, and its ingenuity and importance, his elucidations do not appear to have attracted the least attention; and seem, indeed, to have been completely forgotten. So much so was this the case, that when, in 1815, Mr. Malthus and Sir Edward West published tracts explaining the nature and origin of rent, they were universally believed to be the authors of the theory. Although, however, there is, we believe, no doubt as to their originality, still they were merely the expositors of a theory that had been clearly and ably explained above forty years previously to the publication of their tracts.

Rent, in Law, is defined "a certain profit issuing yearly out of lands and tenements corporeal," not necessarily, although by English usage generally, consisting in money. There are at common law three kinds of rents: 1. Rent-service; having some incident of feudal service connected with it, for which the landlord might distrain of common right. 2. Rent-charge, where the owner of the rent had no future interest or reversion expectant on the land; as where one having parted with his land reserved a rent, with a clause of distress in the deed, by which the land was *charged* with the payment of the rent. 3. Rent-seck, *reditus siccus*, which was rent reserved by deed without a clause of distress. But the common remedy of distress was extended to all these divisions of rent by 4 G. 2. c. 38. (*See* Distress.) The ordinary remedy by action is in *debt*, for the breach of the express contract; or *covenant* may be brought for the breach of a covenant to pay rent. And these actions may be brought at any time within twenty years after the cause of action shall have accrued. A "fee-farm-rent" is a rent issuing out of an estate in fee. The common term "rack-rent" has no particular legal acceptation, and merely means a rent at or near the full value of the premises demised.

REPE'AT. In Music, a character :𝄋: denoting the repetition of the part which it bounds. It is sometimes expressed by dots against the bar, and sometimes by the words *Da Capo*.

REPEATING CIRCLE. In order to diminish the effect of errors of graduation, and to obtain very accurate measurements by means of comparatively small, and therefore portable instruments, a method of observing was invented, or rather brought into use, by Borda, which is now extensively employed, especially in geodetical operations. The method, which consists in moving the telescope successively over portions of the graduated limb corresponding to the angle to be measured, and reading only the multiple arc, may be advantageously applied to circular instruments destined for very different purposes: as, for example, to an instrument for the measurement of the zenith distances of stars or terrestrial objects, or the distance of two trigonometrical stations, in which case it is simply called a *repeating circle;* to a reflecting circle used for observations at sea, when it becomes a *repeating reflecting circle;* or to a theodolite, when it becomes a *repeating theodolite*.

For the purpose of giving an idea of the principle of this method, we borrow the following illustration from Sir J. Herschel: — "Let P Q be two objects, which we may suppose fixed for purposes of mere explanation; and let K L be a telescope moveable on O, the common axis of two circles, A M L and A B C, of which the former, A M L, is absolutely fixed in the plane of the objects, and carries the graduations freely moveable on the axis. The telescope is attached permanently to the latter circle, and moves with it. An arm, O *a* A, carries the index or vernier, which reads off the graduated limb of the fixed circle. This arm is provided with two clamps, by which it can be temporarily connected with either circle, and detached at pleasure. Suppose now the telescope directed to P. Clamp the index O A to the *inner* circle, and unclamp it from the outer, and read off; then carry the telescope round to the other object Q. In so doing the inner circle, and the index arm, which is clamped to it, will also be carried round over an arc A B on the graduated limb of the outer equal to the angle P O Q. Now clamp the index to the *outer* circle, and unclamp the inner, and read off. The difference of readings will of course measure the angle P O Q; but the result will be liable to two sources of error, that of graduation, and that of observation, both of which it is our object to get rid of. To this end transfer the telescope back to P, *without* unclamping the outer circle; then, having made the bisection of P, clamp the arm to *b*, and unclamp it from B, and again transfer the telescope to Q, by which the arm will now be carried with it to C over a second arc B C equal to the angle P O Q. Now again read off; then will the difference between this reading and the *original* one measure *twice* the angle P O Q, affected with both errors of observation, but only with the same error of graduation as before. Let this process be repeated as often as we please (suppose ten times); then will the final arc A B C D read off on the circle be ten times the required angle, affected by the joint errors of all the ten observations, but only by the same constant error of graduation, which depends on the initial and final readings off alone. Now the errors of observation, when numerous, tend to balance and destroy one another: so that, if sufficiently multiplied, their influence will disappear from the result. There remains, then, only the constant error of graduation, which comes to be divided in the final result by the number of observations, and is therefore diminished in its influence to one tenth of its possible amount, or to less if need be." (*Astronomy*, *Cab. Cyc.*, p. 105.)



When the repeating circle is used for measuring zenith distances, it is constructed so as to be capable of being turned round on a vertical pivot, the direction of which passes through its centre, and to which its plane is parallel, and also of turning in its own plane about a horizontal axis. The instrument being placed in the same vertical plane with the star, the telescope is directed to the star and the bisection made; the telescope, which carries the verniers with it, is then firmly clamped to the circle, and the circle turned round 180° in azimuth about the vertical pivot. If the circle be now kept fast, the telescope unclamped and carried round till the star is again bisected, it is plain that the arc of the limb passed over by the verniers in consequence of this motion of the telescope will be double the zenith distance of the star. The same process is repeated as often as may be thought necessary. For the purpose of geodetical measurements the circle is usually furnished with two telescopes, one on the face, and the other on the back; and so placed that the optical axes of both are exactly in the plane of the circle. The circles used by Mechain and Delambre in the operations connected with the measurement of the French arc of meridian, were about 4-tenths of a mètre (nearly 16 inches) in diameter, and were divided into arcs equivalent to about 32 sexagesimal seconds, which were subdivided into tenths by the verniers.

The merit of first applying the ingenious principle of repetition to angular measurements belongs to Tobias Mayer; but it was Borda, as above stated, who first brought the instrument into general use.

For a description of the repeating circle, its adjustments, and the method of using it, see Biot, *Astronomie Physique*, tome i.; Delambre, *Astronomie*, or *Base Metrique*, tome i.; Puissant, *Traité de Géodésie; Raper's Practice of Navigation*, &c. The comparative advantages and defects of the instrument are very clearly stated in a paper by Troughton in the first volume of the *Memoirs of the Royal Astronomical Society*.

REPE'LLENTS. Applications to the surface of the body which appear to make disorders retreat inwards.

REPE'LLING POWER. *See* Repulsion.

RE'PENT (Lat. repo, *I creep*), in Zoology, is used in the same sense as creeping, and is applied to those animals which move with the body close to the ground, either without the aid of legs, or by means of more than four pairs of short legs.

RE'PETEND. In Arithmetic, that part of a *repeating decimal* which recurs continually ad infinitum. It is called a simple repetend when there is but one figure, as ·233. . . ad inf.; and a compound repetend when there

are more figures than one in the repeating period, as ·029029. . . . ad inf. It is usual to mark the first and last figures of the period by dots placed over them; thus the repetends above mentioned are written ·3̇, and ·0̇29̇.

REPLE'VIN, in Law, is an action of tort, in which the plaintiff seeks the recovery of goods illegally distrained. *See* ACTION.

REPLICA'TION. In Law, the third stage in the pleadings in an action, being the plaintiff's answer to the defendant's plea. *See* PLEADING.

REPO'SE. (Lat. repono, *I lie down.*) In the Fine Arts, the absence of that agitation which is induced by the scattering and division of a subject into too many unconnected parts, in which case a work is said to want repose. Where repose is wanting from this cause, "the eye," says Sir Joshua Reynolds, "is perplexed and fatigued, from not knowing where to rest, where to find the principal action, or which is the principal figure; for where all are making equal pretensions to notice, all are in danger of neglect."

REPRESENTA'TION. (Lat. representatio.) In Politics, the part performed by a deputy chosen by a constituent body to support its interests and act in its name on a public occasion. Thus a plenipotentiary represents the sovereign or the state which delegates him at a foreign court. But the most ordinary use of the word is to express the principal function of the delegate of a constituency in a legislative assembly. Representation, in this sense, was unknown to the political systems of the ancients, and seems to have originated in the necessities and usages of feudal times: the lord not being able to levy aid from his vassals without their consent, it became customary for these to delegate powers to individuals from among their numbers to attend his summons and confer with him respecting the aid required. Hence, in our own country, the representation of county freeholders by knights, of communities by their chosen burgesses, in parliament. The most complete early model of a representative feudal assembly is to be found in the parliament of the Sicilies under the Suabian kings; but England is the only country in which it has expanded regularly into a legislature.

The chief question, in political science, regarding the system of representation is, how far each delegate represents the opinions of the local body which sends him, and is bound to act in obedience to their directions. This was unquestionably the early notion of representation. But the constitutional principle of English statesmen has been in general very different. It is, that each member represents, not the local body, but the entire nation. The ties which bind him to his constituents are altogether subordinate to those which attach to him in a general character. He is bound to sacrifice not only the wishes, but the immediate and local interests of the body which sends him, if they are in opposition to the general good of the country. The most popular and best known exposition of this doctrine is perhaps to be found in Burke's famous speech to the electors of Bristol. It follows as a corollary, that constituencies act unconstitutionally in demanding pledges of candidates for their representation as to the part which they are to take on particular questions. But this, like other rules of constitutional conduct, must not be pressed too far. Constituencies, as well as representatives, are bound to use their powers for the general good of the nation; and there may be occasions, although rarely, on which those powers are best used by taking security of the representative that his conduct, on some very important and critical questions, will be in accordance with what they deem the national view. (See *Bentham's Rationale of Representation.*)

REPRESENTATION. In Painting and the other Arts, the transference to a plane of a solid mass, or the appearance of an object to the eye.

REPRIE'VE. (From the Fr. reprendre, *to take back.*) In Law, the suspension of the execution of sentence on judgment in a criminal case for a certain time. Reprieve at the will of the judge is arbitrary; and the latter has power to give it where he is dissatisfied with the verdict, in order to give time to apply to the crown for a pardon. Reprieve is also *ex necessitate legis;* as, a woman capitally convicted has a right to a reprieve during pregnancy; or when a party becomes insane between judgment and award of execution.

REPRI'SALS, LETTERS OF. In National Law, the capture of property belonging to the subjects of a foreign power in satisfaction of losses sustained by a citizen of the capturing state. (*See* LETTERS OF MARQUE.) Letters of reprisal are grantable by the law of nations, where the subject of one state has been oppressed or injured by the subjects of another, and where justice has been refused on application by letters of request. The mode of serving out letters of marque and reprisal in time of truce was regulated by statute 4 Hen. 5. c. 7., but has been long disused. The power of granting letters of marque and reprisal is sometimes given by proclamation of the king in council to the lords of the admiralty.

REPRI'SES. In Law, deductions or payments out of the value of lands; such as rent-charges, or annuities.

REPROBA'TION, in Theology, is a term commonly applied to the supralapsarian tenet of the consignment of all mankind to eternal punishment, with the exception of those whom God has arbitrarily selected for eternal happiness. *See* ELECTION, PREDESTINATION.

REPRODU'CTION. (Lat. reproduco, *I reproduce.*) This word, in Physiology, is sometimes used for generation; but it signifies properly the power which a fully developed organized being possesses to push forth and form anew parts of the body which have been cut off. Vegetables possess this faculty in an eminent degree, and animals have the power of reproduction in proportion as they resemble vegetables in the simplicity of their organization; thus the freshwater polype *Hydra viridis*, when divided into many pieces, reproduces all its characteristic organs out of each piece. Worms and other Annelides can reproduce many segments of the body. Snails can push forth new horns, and reproduce even a great part of the head. Lobsters and spiders thus gain new claws or legs. Newts and lizards reproduce their tails.

REPTA'TION. A mode of progression by advancing successively parts of the trunk, which occupy the place of the anterior parts which are carried forwards, as in serpents: also applied to the slow progression of those animals whose extremities are so short that the body touches the ground.

RE'PTILES, *Reptilia*. (Lat. repo, *I creep.*) The name of a class of cold-blooded Vertebrate animals, including all those which have lungs, and a heart composed of two auricles and one ventricle. Those which retain their gills during the whole or a part of their existence are termed *Batrachians* or *Amphibia:* the latter name Linnæus applied to the whole group, as well as to certain true fishes. (*See* AMPHIBIANS, CHELONIANS, SAURIANS, OPHIDIANS, and BATRACHIANS.) Cuvier, in characterizing the class of reptiles as defined by him, well observes, that as it is from respiration that the blood derives its heat, and the muscular fibre its susceptibility of nervous irritation, the blood of reptiles is cold, and the muscular energy less than that of quadrupeds, and much less than that of birds. Thus we find their movements usually confined to crawling and swimming; for though at certain times several of them jump and run with considerable activity, their habits are generally lazy, their digestion excessively slow, and their sensations obtuse. In cold or temperate climates, almost all of them pass the winter in a state of torpor. Their brain, which is proportionally very small, is not so essentially requisite to the exercise of their animal and vital faculties as to the members of the two first classes: their sensations seem to be less referred to a common centre, for they continue to live and to exhibit voluntary motions long after losing their brain, and even after the loss of their head. A communication with the nervous system is also much less necessary to the contraction of their fibres, and their muscles preserve their irritability after being severed from the body much longer than those of the preceding classes: their heart continues to pulsate for hours after it has been torn away, nor does its loss prevent the body from moving for a long time.

The smallness of the pulmonary vessels permits reptiles to suspend the process of respiration, without arresting the course of the blood; thus they dive with more facility, and remain longer under water than either the Mammalia or birds.

No reptile hatches its eggs. The young Batrachians on quitting the egg have the form and branchiæ of fishes, and some of the genera preserve these organs even after the development of their lungs.

The quantity of respiration in reptiles is not fixed, like that of the Mammalia and birds, but varies with the proportion of the diameter of the pulmonary artery compared to that of the aorta. Thus tortoises and lizards respire more than frogs, &c.; and hence a much greater difference of sensibility and energy is manifested in this class than can exist between one of the Mammalia and another, or between birds. *See* ERPETOLOGY.

REPU'BLIC. (Lat. respublica, *commonwealth.*) That form of government in which the supreme power is vested in the people. A republic may be either an aristocracy or a democracy: the supreme power, in the former, being consigned to the nobles or a few privileged individuals, as was formerly the case in Venice and Genoa; while, in the latter, it is placed in the hands of rulers chosen by and from the whole body of the people, or by their representatives assembled in a congress or national assembly. The free towns of the Continent, Hamburg, Frankfort, Lübeck, and Bremen, are instances of this latter form of government; but the most perfect example of it is to be found in the United States, in Texas, and in some of the South American confederations which have shaken off the Spanish yoke. In Switzerland, aristocracy is blended with democracy in the form of government.

REQUE'ST, LETTERS OF. In Ecclesiastical Law, an instrument by which the regular judge of a cause waives or remits his own jurisdiction, under the provisions of the Statute of Citations, 23 H. 8. c. 9.; in which event the jurisdiction of the appellate court attaches.

REQUESTS, COURT OF. 1. An ancient court of equity, inferior to the Court of Chancery, of which the lord privy seal was chief judge; taken away by 16 & 17 C. 1. c. 10. 2. The Court of Conscience, or of Requests, of London, for the recovery of small debts, was erected in the 9th year of H. 8., with jurisdiction between citizens and freemen in cases of debt or damages under 40*s*., extended in the reign of G. 3. to 5*l*. The local courts instituted in many parts of the kingdom for the recovery of small debts by summary process are hence called popularly Courts of Requests. Many of them are very recently erected, or in process of erection, under local acts. The number of causes tried in the Southwark Court of Requests in 1837, under 40*s*., was 14,474; above that sum, 3333.

RE'QUIEM. (Lat.) In the Roman Catholic Church, a mass performed for the repose of the souls of deceased persons. It is so called from the prayer commencing "Requiem æternam dona iis Domine." The term is also applied to grand musical compositions performed on solemn occasions in honour of deceased civil or ecclesiastical dignitaries. The requiems composed by Mozart, Jomelli, and Cherubini are well known.

RE'SCRIPTS. (Lat. rescribo, *I write back.*) In the Civil Law, answers of popes and emperors to questions in jurisprudence propounded to them officially. Those of the Roman emperors constitute one of the authoritative sources of the civil law.

RE'SCUE. In Law, in the more general sense, a species of resistance against lawful authority; as, by delivering one arrested out of the hands of those who have legal custody of him. In a more restricted application, the term rescue means the taking away and setting at liberty, against law, any distress taken for rent, or services, or damage feasant.

RESEDA'CEÆ. (Reseda, one of the genera.) A natural order of herbaceous or suffrutescent Exogens, inhabiting Europe and Asia. There are but three genera belonging to it; and of these but one species, the common *mignonette*, a Barbary plant, now an universal favourite for the sake of its peculiar fragrance, is the only species possessing any interest except to the botanist.

RESERVOIR. (Fr.) A tank, or pond, in which water is collected and preserved in order to be conveyed through pipes for the supply of a town, &c. Thus, Edinburgh is chiefly supplied with water by springs collected in a magnificent reservoir seven miles distant from the city. The term is also applied to a place where water is collected and preserved for the more regular supply of a fountain or drinking trough in seasons when it is not naturally abundant.

RE'SIDENCE OF CLERGYMEN ON THEIR BENEFICES, is enjoined by the common law of England, as well as by the canon law and many statutory provisions. These last are now consolidated by 1 & 2 Vict. c. 106. Under that act, an incumbent is considered to be non-resident if he is absent for one or more periods exceeding in the whole three calendar months in each year; and will be liable to the penalties unless he has obtained a licence for non-residence from the bishop, or is within any of the statutory exemptions. The licence may be given, when there is no house or fit place of residence, to reside in some fit or convenient house described in the licence, which must be within three miles of the church; or within two, if the church be in a city, market, or borough town. The statutory exemptions are in favour of a variety of officers of cathedral and collegiate churches; who may not, however, be absent on account of their residence and performance of duty elsewhere for more than five months. Licences for absence from the benefice may also be granted by the bishop, on petition, for a few other causes: incapacity of mind or body; the dangerous illness of a wife or child, part of the family, — in which case the licence is only for six months, and requires the archbishop's renewal; and in case a house convenient for residence cannot be procured within the benefice. The penalties are fixed in a graduated scale, being the prefixtures of portions of the value of the benefice, and may be proceeded for in the bishop's court. The bishop may also proceed by monition and sequestration.

RE'SIDUE. In Law, the remainder of a testator's estate after payment of debts and legacies: if this remainder be bequeathed to any one, he is styled the residuary legatee. If a legatee dies before the testator, the legacy is a lost or *lapsed* legacy, and sinks into the residue; and this provision of the law is extended to devises of real property by 7 G. 4. and 1 Vict. c. 26. (the Wills Act) s. 25. *See* LEGACY, WILL.

RE'SIN. (Gr. ῥητίνη; from ῥέω, *I flow.*) A proximate principle common in the vegetable kingdom, the ultimate components of which are carbon, oxygen, and hydrogen. There are many varieties of resin. Their general characters are fusibility and inflammability; solubility in alcohol, insolubility in water. They are generally separable into two distinct portions by the action of cold and of hot alcohol. They are valuable as ingredients in varnishes, and several of them are used in medicine. They are often naturally blended with modifications of gum, in which case they constitute the series of *gum resins*. The specific gravity of the resins varies between 1·0 and 1·4. They become negatively electric by friction. The commonest resin in use, usually called *rosin*, is obtained by distilling turpentine: the volatile oil passes over, and the resin remains in the still.

RESI'STANCE, in Mechanics, denotes generally a force acting in opposition to another force, so as to destroy it or diminish its effect. Resistance is sometimes considered as of two kinds, active and passive; the active resistance being that which corresponds to the useful effect produced by a machine, and the passive that which belongs to the inertia of the machine. Thus, in raising water from a well, the active resistance to the force employed is measured by the quantity of water which is raised; and the passive resistance by the force required to overcome the weight of the bucket and the rope, the friction of the pulley on its axle, &c.

RESISTANCE OF FLUIDS. In Hydrodynamics, the force with which a solid body moving through a fluid is resisted or retarded. Of all the different kinds of resistance which manifest themselves among bodies, there is none of greater importance than this, on account of its application to the theory of naval architecture.

Sir Isaac Newton was the first who gave a general theory of the motions and actions of fluids. (*See* HYDRODYNAMICS.) The Newtonian theory of the resistance of fluids, which is given in the second book of the *Principia*, is founded on the assumption of the perfect intermobility of the particles of the fluid, and the equal propagation of pressure in all directions. These are, indeed, the characteristic properties of fluidity; nevertheless, the results of the mathematical theory differ so widely in many cases from actual experiment, that some philosophers have called in question the accuracy of the principles from which they are derived. The theory, however, notwithstanding its defects, furnishes some propositions of great practical use, and, indeed, forms the groundwork of all our knowledge on the subject. We shall here give a general view of its leading principles.

It is evident that a solid body, in moving through a fluid, must communicate a motion to the fluid particles with which it successively comes in contact. Now, the quantity of motion communicated to the fluid is necessarily equal to that which is lost by the solid, and may therefore be taken as the measure of the resistance. To determine this quantity of motion, let us conceive a cylindrical or prismatic body, terminated by a plane perpendicular to its axis, to be propelled through a non-elastic fluid in the direction of its axis, so that the particles of the fluid strike against the plane perpendicularly: and let A denote the area of the anterior surface of the body, ρ the density of the fluid, and v the velocity of the motion, during the small interval of time dt. Then the space described by the body in the time dt is $v\,dt$; the volume of the fluid displaced in that time is $A\,v\,dt$; the mass of the fluid displaced is $\rho\,A\,v\,dt$; and the momentum or quantity of motion imparted to the fluid is $\rho\,A\,v\,dt \times v = \rho\,A\,v^2\,dt$. Let R denote the resistance of the fluid, we have then

$$R = \rho\,A\,v^2\,dt \quad . \; . \; . \; . \quad (1.)$$

From this equation it appears that the resistance upon a plane surface, moved perpendicularly through a non-elastic fluid at rest, is proportional to the density of the fluid, to the area of the plane, and to the square of the velocity.

We may deduce from equation (1.) a measure of the force of resistance by comparing it with the pressure of gravity. Let h denote the height from which a heavy body must fall in order to acquire the velocity v, and let g be the accelerating force of gravity (32 feet in a second); we have then (*see* FORCE) $v^2 = 2\,g\,h$, and by substituting this in equation (1.), we get

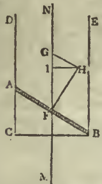
$$R = 2\,\rho\,A\,h \times g\,dt \quad . \; . \; . \; . \quad (2.)$$

Now, since g is the velocity generated by gravity in one second, $g\,dt$ is the velocity generated in the time dt; and since $2\,\rho\,A\,h$ expresses the mass of a prism of the fluid, having A for the area of its base and $2\,h$ for its altitude, $2\,\rho\,A\,h \times g\,dt$ is the quantity of motion which the prism would acquire by the free action of gravity in the time dt; in other words, its weight. We have, therefore, this proposition: *The direct resistance of an unelastic fluid on any plane surface is equal to the weight of a column of the fluid having the surface for its base, and for its altitude twice the height due to the velocity with which the surface moves through the fluid.* Let W be the weight of the unit of volume of the liquid; we have then

$$R = 2\,W\,A\,h \quad . \; . \; . \; . \quad (3.)$$

The above measure of the force of resistance is deduced

on the supposition that the direction of the motion is perpendicular to the plane. If the shock is received obliquely, the resistance will be greatly diminished. Let A B represent the profile of the plane, and M N the direction of the motion of the plane in stagnant water, or of a vein of fluid D C B E striking against the plane, supposed to be fixed. Let F be the intersection of M N with A B, and draw B C perpendicular to M N. Now, if A denote the area of the given plane A B, v the velocity of the motion, and R the direct resistance due to the velocity v (that is, the resistance which the plane would sustain if placed perpendicularly to M N); then (1.) we have $R = \varrho\, A\, v^2\, d\, t$. On F N take F G, to represent R. This force F G may be resolved into two, F H perpendicular and H G parallel to A B, of which the latter produces no effect on the plane; hence the resistance is diminished, by reason of the oblique impact, in the ratio of F H : F G, or of sin. i : 1 (i denoting the angle of incidence A F N). But, again, the absolute resistance is also proportional to the number of filaments which strike the plane; and it is obvious that the number which would strike it in the oblique position A B is less than the number which would strike it if directly opposed to the stream, in the ratio of B C : B A, or of sin. i : 1. Compounding this with the former ratio, the total diminution of resistance is as sin. $^2 i$: 1; that is, to say, the absolute resistance or pressure in the direction F H perpendicular to the plane is R sin. $^2 i$.



It still remains to find the effective impulse or resistance in the direction of the motion. Draw H I perpendicular to M N. The force in the direction F H may be resolved into F I and I H, of which the effective part is F I. Hence the effective impulse is to the absolute oblique impulse as F I to F H, or as sin. i : 1; consequently the effective impulse on the plane in the direction M N is R sin. $^3 i$. Let this be denoted by R′; we have then

$$R' = R \sin.\,^3 i = \varrho\, A\, v^2\, d\, t \times \sin.\,^3 i \quad . \ . \ . \ . \ (4.)$$

If we denote by A′ the area of the projection of the plane A B upon a plane perpendicular to M N, we have $A' = A \cos.\ A\,B\,C = A \sin.\ i$; and since $\varrho\, v^2\, d\, t = 2\, W\, h$, the above formula becomes, by substitution,

$$R' = 2\, W\, A'\, h \sin.\,^2 i \quad . \ . \ . \ . \ (5.)$$

From this last formula the effective oblique impulse in the direction of the stream upon any plane surface is easily computed. For other surfaces than planes, it is necessary to find an expression for the resistance on the differential element of the surface, which may be regarded as coinciding with its tangent plane; and the sum of all these resistances, found by the usual process of integration, will give the whole resistance on the surface. For a surface of revolution we have

$$d\, A' = 2\, \pi\, y\, d\, y \text{ and } \sin.\,^2 i = \left(\frac{d\, y}{d\, z}\right)^2;$$

therefore,

$$R' = 4\, \pi\, W\, h \int y \frac{dy^3}{d\, x^2}.$$

Numerous experiments have been made for the purpose of ascertaining how far this theory of the resistance of fluids agrees with the actual facts, or for forming an empirical theory for the guidance of the engineer. Of the details of these experiments our limits will not permit us to give an account; but the principal experimenters, and works in which the results may be found, are the following: Sir Isaac Newton (*Principia*, lib. ii.); Mariotte (*Traité des Mouvemens des Eaux*); Gravesande (*System of Natural Philosophy*); D. Bernoulli and Krafft (*Comment. Petropol.*); Borda (*Mém. de l'Acad. des Sciences de Paris*, 1763 and 1767); Condorcet, D'Alembert, and Bossut, by order of the French government in 1775; Bossut (*Hydrodynamique*); Du Buat (*Principes d'Hydraulique*); Robins (*Gunnery*); Don George d'Ulloa (*Examen Maritimo*); Coulomb (*Mém. de l'Institut*, tom. iii.); Vince (*Phil. Trans.*); Hutton (*Tracts*); Beaufoy (*Nautical and Hydraulic Experiments*); Russel (*Trans. of the Royal Society of Edin.* vol. xiv.), &c. The general results of the experiments may be stated as follows: —

I. The force of resistance on bodies moving in fluids is proportional to the square of the velocity, at least within the limits of 2 to 10 feet per second. This is in accordance with the theory.

II. The direct resistance on bodies moving with the same velocities is nearly in the ratio of the surfaces.

III. The resistances on surfaces moving obliquely do not by any means vary in the ratio of the squares of the sines of the angles of incidence, especially when the incidence is very oblique; and for such motions the theory must be entirely abandoned.

The above results are, however, considerably modified by various circumstances, of which the principal are the following: —

1. The form of the body. The Newtonian theory takes account only of the anterior surface of the body; but it was clearly established by the experiments of Du Buat that the form of the hinder part is not less efficacious in modifying the resistance. A prismatic body, having its prow and poop equal and parallel surfaces, being plunged horizontally into a stream, will require, in order to keep it immoveable, a force in the direction of its axis equal to the difference of the real pressures exerted on its prow and poop. If the fluid is at rest, this difference will be nothing, because the opposite dead pressures are equal; but in a stream there is superadded to the dead pressure on the prow the active pressure arising from the deflection of the filaments of the fluid, which being turned aside and rendered divergent by the obstruction of the anterior surface, a part of the pressure of the circumambient fluid is employed in turning them into the trough behind the body, and consequently there is less pressure on the posterior surface than if the body were at rest in stagnant water, so that the body is impelled backwards. This force is called by Du Buat the *non-pressure*, by Beaufoy the *minus pressure*. Now, the whole impulse to be withstood if the body is in a stream, or the resistance to be overcome if it moves in stagnant water, is the sum of the active pressure on the fore part and the non-pressure on the hinder part; and this does not depend solely on the form of the prow and poop, but also, and perhaps chiefly, on the length of the body. The non-pressure on a cube was found by experiment to be reduced to a fourth part, by making the length of the body triple of the breadth. The mere lengthening of a ship, without changing the form of the prow or poop, increases the speed.

2. Another circumstance which modifies the general results is the velocity of the body. It was ascertained, by Mr. Russel's experiments on canal boats, that the resistance does not follow the ratio of the squares of the velocities, excepting when the velocity is small and the depth considerable; but that the increments of the resistance are greater than those due to the squares of the velocities as the velocity approaches to a certain limit depending on the depth of the fluid; and that immediately after passing this limit the resistance suffers a sudden diminution, and becomes much less than that due to the square of the velocity. In a canal about five and a half feet deep this limit (which is the velocity of the wave generated by the motion of the body) was found to be from 11 to 12 feet per second, or about eight miles per hour.

3. A third cause which modifies the theory is the adhesion of the molecules of the fluid, which is most sensible when the motion is slow and the body small and very long. In such cases, it becomes necessary to add a term depending on the first power of the velocity.

4. The resistance is also influenced by the depth of the body under the surface of the water. When the body is near the surface the resistance is greater than when it is at the depth of six feet. When a body floats the fluid is heaped up, as it were, before the anterior surface, by which the resistance is increased.

5. In elastic fluids, as the density increases with the pressure, the density of the fluid before the anterior surface increases with the velocity, and the increments of the resistance are greater than in the ratio of the square of the velocity. In this case, also, we may conceive a velocity so great that the pressure on the posterior surface becomes negative, as in the case of a cannon ball projected with a velocity greater than that with which air rushes into a vacuum. When this takes place the fluid is not even in contact with the posterior surfaces of the ball, and the character of the resistance is wholly changed. *See* PROJECTILES.

6. When a body moves in a fluid a portion of the fluid adheres to the body, and accompanies it in its motion; whereby the form of the moving body is altered, and the resistance increased. The quantity of fluid thus dragged along is independent of the velocity, and was estimated by Du Buat, from experiments made on spheres vibrating in water, to increase the quantity of displaced fluid in the ratio of 1 to 1·6. His experiments on prisms also showed that the quantity of dragged fluid was proportional to the bulk of the moving body. Mr. Baily (*Phil. Trans.* 1832) gives, as the mean results of his experiments on pendulums swinging in air, the ratio 1 to 1·846 as the increase of the displaced fluid from this cause; and remarks that the quantity appeared to depend on the form as well as magnitude of the moving body, but not on its weight or specific gravity. This circumstance, which considerably modifies the resistance, though made known by Du Buat in 1786, was overlooked by other experimenters, until rediscovered by Bessel in 1826, when engaged on experiments to determine the length of the seconds' pendulum.

From the above considerations, it may be inferred that the resistance R opposed to any body moving through a fluid, considered as a pressure of so many pounds weight, will be expressed by an equation of this form,

$$R = (m + n)\, W\, A\, h;$$

where W is the weight in pounds of the unit of volume of the fluid (one cubic foot); A the area of the greatest transverse section of the body, expressed in square feet; h

the height in feet due to the velocity, so that $h = v^2 \div 64$; and m and n numerical coefficients, constant for bodies of similar figure, but variable for bodies of different figures, and to be determined by experiment for each kind of body; m having reference to the impulse and pressure on the anterior surface, and n to the non-pressure on the posterior part.* The following are a few of the cases for which values of m and n have been found.

When a thin plate is directly opposed to the impulse of a stream, the value of $m + n$ appears to increase with the area. If A is equal to a tenth of a square foot, $m + n = 1{\cdot}4$; and if $A = 1$ square foot, $m + n = 1{\cdot}9$. The value of $m + n$ for surfaces of larger dimensions has not been sufficiently determined. For a prismatic body terminated by two planes, the pressure against the anterior force remains constant; but the non-pressure, or value of n, diminishes as the length increases. For a cube held fast in a stream, Du Buat found $m + n = 1{\cdot}46$; and for a prism whose length was from three to six times the square root of its face, $m + n = 1{\cdot}34$. But when the bodies moved in still water, he found, as for the thin plate, $m + n = 1{\cdot}43$; for the cube, $m + n = 1{\cdot}17$; and for the prism, $m + n = 1{\cdot}10$.

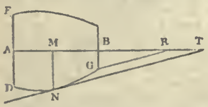
By means of these values the actual resistances are readily computed for each body, when the velocity is given. Suppose the velocity to be 3 feet per second, and the opposing surface in each case to be 1 square foot. For $v = 3$, we have $h = 9 \div 64 = {\cdot}1406$. With respect to W, the weight of an imperial gallon of water, at temperature 62° and under the mean pressure, is 10 lbs. avoirdupois; but an imperial gallon contains 277·27 cubic inches, whence the weight of a cubic foot of water is 62·3 lbs. avoirdupois. Hence, if the bodies are impelled through stagnant water with a velocity of 3 feet per second, the absolute resistances in each case are as under: —

For the thin plate	$R = 1{\cdot}43 \times 62{\cdot}3 \times {\cdot}1406 = 12{\cdot}5$ lbs.
For the cube	$R = 1{\cdot}17 \times 62{\cdot}3 \times {\cdot}1406 = 10{\cdot}2$
For the prism	$R = 1{\cdot}10 \times 62{\cdot}3 \times {\cdot}1406 = 9{\cdot}6$

The effect produced by the addition of a poop or prow was also determined by Du Buat. The addition of a poop to a prismatic body whose length is four or five times its breadth only diminishes the resistance by a tenth part. But when a prow consisting of two equal vertical planes, making with each other an angle of 60°, was added, the resistance was reduced to about a half. On giving the prow the form of a semicylinder, the resistance was also reduced about a half. The section of the prow being a triangle whose height was double the base or breadth of the prism, the resistance was reduced to two fifths. In general, a prow having a curved surface produces a greater diminution of the resistance than one of equal magnitude terminated by plane surfaces.

For a sphere moving in water or in air with a moderate velocity, the experiments give $m + n = 0{\cdot}6$; but this value increases when the velocity becomes great, as in the case of a projectile. The experiments of Bossut on the model of a ship moved in the direction of its axis gave $m + n = 0{\cdot}16$. This may be considered as the value corresponding to the solid of least resistance. For the effect with which solid bodies resist an effort tending to break or crush them, see STRENGTH OF MATERIALS; and for the resistance of the atmosphere on a projectile, see GUNNERY, PROJECTILE.

RESI'STANCE, SOLID OF LEAST. In Mechanics, the solid whose figure is such that in its motion through a fluid it sustains the least resistance of all others having the same length and base; or, on the other hand, being stationary in a current of fluid, offers the least interruption to the progress of that fluid. In the former case, it has been considered the best form for the stem of a ship; in the latter, the proper form for the pier of a bridge. The determination of the curve whose revolution gives the body having this property is a problem which can be solved by the ordinary methods of maxima and minima, when the law of resistance is assumed. On the hypothesis that the resistance is proportional to the square of the velocity, Newton gave the following construction:



— Let a curve D G be so taken that if from any point N in it an ordinate N M be drawn perpendicular to the axis A B, and from a given point G the line G R be drawn parallel to the tangent N T at N, cutting the axis in R; then if $MN : GR :: GR^3 : 4\,BR \cdot BG^2$, the solid generated by the revolution of this curve about the axis A B will be the solid of least resistance. (*Principia*, lib. ii. prop. 34.)

RESOLU'TION. (Lat. resolutio.) In Medicine and Surgery, this term implies the cessation or dispersion of inflammatory action without the formation of an abscess or mortification.

RESOLUTION. In Music, the writing out of a canon or fugue in partition from a single line.

RESOLUTION OF A DISCORD. The descent by a tone or a semitone, according as the mode may require, of a discord which has been heard in the preceding harmony.

RESOLUTION OF EQUATIONS. The finding the values which the unknown quantity or quantities must have, so as to fulfil the conditions expressed in the proposed equation; viz. of rendering the aggregate value of all the positive terms equal to the aggregate value of all the negative terms. These values are called the *roots of the equation*. See EQUATION.

RESOLUTION OF FORCES. *See* RESULTANT.

RESOLUTION, or SOLUTION, in Mathematics, is the orderly enumeration of the things to be done to obtain what is required in a problem. A problem may be divided into three parts, — the proposition, the resolution, and the demonstration.

RE'SONANCE. (Lat. resonans.) In Music, the returning of sound by the air acting on the bodies of stringed musical instruments.

RESPIRA'TION. (Lat. respiro, *I breathe*.) The function by which the nutrient circulating fluid of an organized body is submitted to the influence of air, for the purpose of changing its properties. The great end which appears to be answered by respiration is the removal of carbon, in the form of *carbonic acid*, from venous blood. This gas is accordingly found in the air which is expired from the lungs; and the blood, having lost its carbonic acid, at the same time loses its dingy hue, and acquires the florid red which characterizes arterial blood. It has been shown by Dr. Stevens that a peculiar attraction exists (not chemical) between oxygen and carbonic acid, which acts through membranes, and in consequence of which the carbonic acid appears to be attracted, as it were, out of the venous blood, by the oxygen of the air in the cellular structure of the lungs; while, at the same time, a portion of oxygen, probably equal in bulk to that of the emitted carbonic acid, is absorbed by the blood, and contributes to its arterial characters. The change from the arterial to the venous state, and consequently the formation of carbonic acid, appears to take place in the capillary junctions of the artery and vein; but how it is there effected we know not.

From the quantity of carbonic acid emitted from the lungs in a given time, it has been attempted to ascertain the quantity of carbon which is thus thrown off; but the usual estimates upon this subject, which place it at about 12 ounces in the 24 hours, are probably overrated, inasmuch as that quantity of carbon is more than exists in the food daily taken into the stomach. If we average it at 6 ounces, it will probably be nearer the truth; and 6 ounces of charcoal are equal to 22 ounces of carbonic acid gas. Besides carbonic acid, there is also a quantity of aqueous vapour thrown out with the expired air; this is probably chiefly produced by the superficial exhalents of the lungs, but it may also be partly derived from transpiration from the blood. It has not been satisfactorily ascertained whether nitrogen is taken up by the blood as well as oxygen, though experiments have rendered it probable that a portion of that component of the atmosphere is also absorbed.

RESPIRATION OF PLANTS. *See* BOTANY.

RESPIRATOR. An instrument fitted to cover the mouth, over which it is retained by proper bandages: it is constructed of a series of flattened silver or gilt wires, over and between which the air passes and repasses in the act of respiration and of speaking. It is presumed that the warm air emittted from the lungs imparts its excess of temperature to the small metallic bars, and that these in their turn impart heat to the cold air drawn through them at each inspiration; so that in this way the low temperature of the external air in cold weather is mitigated before it reaches the lungs, and its supposed noxious influence prevented. When a handkerchief is tied over the mouth, and we are obliged to breathe through the nose, the extreme low temperature of the external air is similarly mitigated before it reaches the lungs.

RESPONDE'NTIA. In Mercantile Law, a species of contract; which differs from bottomry, in that the loan is effected on the security of the freight, and not on that of the ship itself. *See* BOTTOMRY.

REST. In Music, a pause or interval of time, during which there is an intermission of the voice or sound. A rest may be for a bar, or more than a bar, or for a part of a bar only.

RESTITU'TION, WRIT OF, in Law, lies where judgment has been reversed, to restore to the defendant what he has lost. It can properly only be granted where the party cannot be restored by the ordinary course of law. Restitution of goods to a party robbed was unknown to the common law; but the stat. 21 H. 8. c. 11. first saw it. By the statute 7 & 8 G. 4. c. 29. s. 57., it is now in the power of the court to award a writ of restitution of goods and chattels, and to restore them in a summary manner, where a thief or fraudulent taker has been indicted on the part of the owner and convicted. Such restitution cannot be granted of a valuable security, where the property has passed into other hands by a boná fide trans-

action. But a writ of restitution will reach goods stolen, although they have been sold in market overt. Restitution can only be had from the person in possession of the goods at the time of and after the felon's conviction.

RESTORATION, THE, in English History, is applied by way of eminence to the accession of Charles II. to the throne after an interregnum of eleven years and four months, from Jan. 30. 1649, when Charles I. was beheaded, till May 29. 1660. The latter day is appointed in the liturgy of the English church as an anniversary festival in commemoration of the restoration of the monarchical form of government in these realms.

RESU'LTANT, in Dynamics, is the force which *results* from the *composition* of two or more forces acting upon a body. When the two forces act upon a body in the same line of direction, the resultant is equivalent to the sum of both; when they act in opposite directions, the resultant is equal to their difference, and acts in the direction of the greater. If the lines of direction of the two forces are inclined to each other, then, on taking in each direction from the point where they intersect a straight line to represent each of the forces respectively, and constructing a parallelogram of which these lines are the sides, the resultant is represented both in intensity and direction by the diagonal of the parallelogram passing through the point of intersection. By combining this resultant with a third force, a new resultant will be obtained; and in this manner the resultant of any number of forces may be determined. *See* COMPOSITION OF FORCES.

RESURRE'CTION. (Lat. resurgo, *I rise again.*) The history of the resurrection of our Saviour is detailed in the separate narration of each of the four Evangelists, and is also referred to and insisted on in the Acts of the Apostles, and in every one of the Epistles. The importance of this history, as an evidence of the truth of Christianity, is pointed out in a peculiar manner by Paley (*Evidences*, part 2. ch. 8.); namely, that it was alleged from the beginning by all the propagators of Christianity, and relied on as the great test of the doctrines which they taught; consequently, if the fact be untrue, they must all have been either deceivers, or deceived in a point on which it is morally impossible they could be so.

RESUSCITA'TION. (Lat. resuscitare, *to arouse.*) This term is generally used to signify the restoring to animation of persons apparently dead. The first and principal object in these cases is to aërate the blood by the artificial introduction of fresh air into the lungs, and to restore the natural function of respiration; the lungs, therefore, must be inflated, and proper stimulants applied when necessary; among these, in cases of drowning and of apparent death from exposure to cold, friction and warm bath are eminently important: after hanging, the vessels of the brain often require to be unloaded by venesection in the jugular vein. Electricity is sometimes resorted to, but generally hopelessly. In all these cases no time should on any account be lost, as every thing depends upon *prompt* treatment, as well as upon *proper* means; and many lives have been lost for want of immediate aid, and skill in applying it. The attempts to restore suspended animation should not be given up till unequivocal proofs of death are manifest. (*See* DROWNING.) The details of the management of different cases of apparent death are too extensive to come within our limits: upon this subject the reader may advantageously consult *Taylor's Elements of Medical Jurisprudence.*

RETA'INER. In old English Law, a servant not dwelling in the master's house or employed by him in any distinct occupation, but wearing his *livery* (*i. e.* hat, badge, or suit), and attending on particular occasions: an important relic of the times of private warfare. The giving liveries, or *retaining* this class of servants, was forbidden by many statutes with little effect. The statutes themselves were repealed by 3 Car. I. c. 1.; but the usage had nearly ceased.

RETAINER, or RETAINING FEE. In the language of the Bar, a fee given to a counsel to secure his services; or rather, as it has been said, to prevent the opposite side from engaging them. A *special* retainer is for a particular case expected to come on. A *general* retainer is given by a party desirous of securing a priority of claim on the counsel's services for any case which he may have in any court which that counsel attends. The effect of it is merely this, that if a counsel having a general retainer receive a special retainer on the other side, he cannot accept it until twenty-four hours after notice shall have been given of its arrival to the party so generally retaining him; when, if he does not receive a brief or a special retainer from the latter, he is bound to accept it. The same word in its strict legal acceptation signifies the engagement of an attorney by his client, which enhances the mutual duties implied by law between them.

RETARDA'TION. The act of hindering the free progress of a body, and ultimately, therefore, stopping it. It arises from the opposition of the medium *in* which the body moves, or from the friction of the surface *upon* which it moves. *See* FRICTION, RESISTANCE.

RE'TE MUCO'SUM. (Lat.) The soft and apparently fibrous matter, or layer, situated between the cuticle and the cutis; it is the seat of the colour of the skin. It is black in the negro, and the colouring matter is of such a nature as to admit of being bleached by the action of chlorine.

RE'TIARIES, *Retiariæ.* (Lat. rete, *a net.*) In Entomology, those spiders are so called which spin a web or net to entrap their prey.

RETIA'RIUS. (Lat. rete, *a net.*) The name of a class of Roman gladiators armed in a peculiar way. The retiarius was furnished with a trident and net, with no more covering than a short tunic; and with these implements he endeavoured to entangle and despatch his adversary, who was called secutor (from sequi, *to follow*), and was armed with a helmet, a shield, and sword.

RETI'CULATE. (Lat. rete.) In Zoology, when a surface has a number of minute impressed lines which intersect each other in various directions, like the meshes of a net.

RETI'CULATED WORK. In Architecture, that wherein the stones are square and laid lozengewise, resembling the meshes of a net. This species of masonry is scarcely ever practised in the present day; but it was very common among the ancients.

RETI'CULATES, *Reticulata.* (Lat. reticulum, *a net.*) The name of a section of Lithophytes, comprehending those in which the polype cells have a reticulate disposition on the surface of expanded plates.

RE'TICULE. In a telescope, a network of some fine fibres crossing each other at right angles, and dividing the field of view into a series of small equal squares. It has been long used for observations on the quantity of the enlightened parts of a luminary during eclipses; and is found, under most circumstances, well adapted for the purpose, when placed in a convenient position in respect to the object-glass of the telescope. The term reticule is also applied to a well-known article, formerly of net-work, but now of every description of materials, used by ladies.

RETI'CULUM. (Lat.) The name of the "honeycomb bag," or second cavity of the complex stomach of the Ruminant quadrupeds; so called because of the reticulate or honeycomb-like disposition of the mostly hexagonal cells which occupy its inner surface.

RE'TINA. (Lat. rete.) The pulpy expansion of the optic nerve in the interior of the eye; it is the seat of vision.

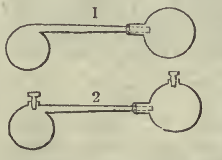
RETINASPHA'LTUM, or RETINITE. (Gr. ρετινη, *resin*, and ασφαλτον, *bitumen*, or *retinite.*) A substance discovered by Mr. Hatchett, associated with Bovey coal, and which has since been found in other coal strata. When digested in alcohol it yields a portion of resin, and asphaltum remains; it appears, therefore, to be a substance intermediate between resin and bitumen, and renders it probable that bitumens are of resinous origin.

RETINI'TIS. Inflammation of the retina.

RE'TIPEDS, *Retipedes.* (Lat. rete, and pes, *a foot.*) The name given by Scopoli to one of the divisions of a binary arrangement of birds, including all those which have the skin of the tarsi divided into small polygonal scales.

RETI'RED FLANK. In Fortification, a flank having an arc of a circle with its convexity turned towards the place.

RETORT. A chemical vessel employed in a variety of distillations. It is generally made of glass or earthenware, and sometimes is provided with a stopper so placed above the bulb as to enable substances to be introduced into it without soiling the neck; in this case it is called a *tubulated* retort. A *receiver* is usually annexed to it for the purpose of collecting the products of distillation. Fig. 1. represents a plain retort and receiver; in fig. 2. both are tubulated.



RETOUCH. In Painting, Sculpture, &c., a verb used to denote the reapplication of the master's hand to a work which he had theretofore considered in a finished state.

RETRACE. In Painting, &c., a verb used to denote the renewal of the outline of a drawing.

RETRENCHMENT. *See* FORTIFICATION.

RETROCE'DENT. A term applied in Medicine to those diseases which move about from one part of the body to another; as *retrocedent gout*, when it leaves the toe for the stomach.

RETROGRADATION. A term applied to the apparent motion of a planet when it is contrary to the order of the signs, or when the planet appears to move westward among the fixed stars. *See* PLANET.

RETU'RN, in Law, in its most usual signification, is applied to writs. The return to a writ is, properly speaking, a recital by the sheriff or other officer to whom

it was directed of what he has done in execution of it; as, for example, in cases of civil process, that the defendant cannot be found (technically called non est inventus), has no goods within the sheriff's bailiwick (nulla bona), and so forth. This is indorsed on the writ; and the writ is then delivered into the court whence it issued on the "return day," or day when the writ is returnable. The remedy against the sheriff for a false return is by action on the case. The return of members of parliament is thus, strictly speaking, the return by the sheriff, or other returning officer, of the writ addressed to him, certifying the election in pursuance of it. *See* Parliament.

Return. In Architecture, a projecture, moulding, or wall continued in a different or opposite direction.

REVE'ILLE. (Fr. literally *awake.*) The name given to the practice prevalent throughout all the European armies of beating the drum at daybreak, to awake the soldiers and put a stop to the challenging of the sentries. The equivalent tune played on the bugle in the evening, to summon the soldiers within their barracks, is called the *retreat*.

REVELA'TION, in a theological sense, is a communication of truth made by God to man; but it is understood that those truths only are revealed which are communicated by direct and special means, that is, by divine inspiration. Such fragments of the divine will and economy as are taught men by their own faculties and instincts are distinguished under the term *natural religion*.

RE'VELS, MASTER OF THE, or LORD OF MISRULE. The name of an officer formerly attached *pro tempore* to royal and other distinguished houses, whose duty it was to preside over the Christmas entertainments. This office was first permanently instituted in the reign of Henry VIII.; and appears to have gone out of fashion towards the end of the 17th century.

REVE'NDICATION. A term of the civil law, signifying a claim legally made to recover property, by one claiming as owner. The right of property must, generally speaking, be complete, to proceed to the action of revendication; thus, no such action can be brought for corporeal things until after delivery, by which they pass.

RE'VENUE. (Fr.) The name given to the income of a state derived from the customs, excise, taxation, and other sources, and appropriated to the payment of the national expenses. Most useful and comprehensive tables, showing the revenue and expenditure of Great Britain, will be found in the Parliamentary Papers printed every session.

RE'VEREND. (Lat. reverendus.) A title of respect given to the clergy. In Roman Catholic countries the members of the different religious orders are styled *reverend*. In England deans are *very reverend*, bishops *right reverend*, and archbishops *most reverend*. In Scotland, the principals of the universities and the moderator of the General Assembly for the time being are styled *very reverend*.

REVE'RSE. In Numismatics, the opposite to the obverse or face of the coin or medal. *See* Obverse, Numismatics.

REVE'RSION, in Law, is defined to be the residue of an estate in lands, tenements, or hereditaments, left in the grantor, to commence in possession after the determination of some particular estate granted by him.

REVE'RSION OF SERIES, in Algebra, is a method of expressing the value of an unknown quantity which is involved in an infinite series of terms, by means of another series of terms involving the powers of the quantity to which the proposed series is equal. Thus, if the proposed series be

$$z = a x + b x^2 + c x^3 + d x^4 + \dots \text{ad inf.} \quad (1.)$$

and if we assume

$$x = A z + B z^2 + C z^3 + D z^4 + \dots \text{ad inf.} \quad (2.)$$

the original series will be reverted on determining the coefficients A, B, C, D, &c.

The ordinary method consists in substituting the last series (2.) and its powers for x and its powers in the series (1.), and equating the coefficients, whereby the values of A, B, C, D, &c. are obtained. But this method, though given by Newton, by whom the problem was first proposed, becomes unmanageable after a few steps; and is moreover defective, inasmuch as it does not show the connection of the coefficients, nor the law by which they are formed. A general formula was given by Arbogast (*Calcul des Derivations*), whereby they may be continued with comparatively little trouble to almost any extent. The values of the first four coefficients are,

$$A = \frac{1}{a},\ B = -\frac{b}{a^3},\ C = \frac{2b^2 - ac}{a^5},$$

$$D = -\frac{5b^3 - 5abc + a^2 d}{a^7}.$$

(See also *Woodehouse's Principles of Analytical Calculation*, arts. 72 and 73.; and the *Penny Cyclopedia*, where the values of the coefficients are given to eleven terms.)

REVE'RSION, REVERSIONARY PAYMENTS. In the doctrine of Annuities, a reversion is a payment which is not to be received, or a benefit which does not begin, until the happening of some event, as the death of a person now living. Payments which are to be received at the end of a specified period of time are usually called *deferred payments*.

The present value of a sum of money to be received on the death of an individual of a given age depends evidently upon the chances which the individual has of surviving each future year of age, combined with the interest of money. The method by which the value is calculated, from an observed or assumed law of mortality, has been explained under the term Assurance; and for the sake of facilitating calculations of this kind, which are of very frequent occurrence in the affairs of life, extensive tables have been published, computed from various hypotheses of mortality, and at different rates of interest. Such tables are usually exhibited in the form of Annuity Tables, from which the solutions of all questions relating to assurances and reversions are easily deduced. *See* Annuity and Assurance.

Let A denote the value of an annuity of $1l.$ on a life of a given age, V the present value of $1l.$ to be received at the end of the year in which the life fails (the year being supposed to commence with the day on which the annuity is payable), r the rate of interest, and $v = 1 \div (1 + r)$; then

$$V = v(1 + A) - A, \text{ or } V = v - (1 - v) A.$$

Suppose, for example, that on the death of *A.*, whose present age is fifty-five, the sum of 5000*l.* is to revert to *B.* or his assigns, and that *B.* proposes to sell his interest in this reversion; and let it be proposed to calculate the sum which he ought now to receive, allowing the purchaser interest at the rate of 4 per cent. per annum. In the table given under the term Annuity the value of an annuity of $1l.$ on a male life aged fifty-five is 11·0392. At 4 per cent. we have $r = {\cdot}04$, and $v = 1 \div 1{\cdot}04$; therefore $V = \frac{12{\cdot}0392}{1{\cdot}04} - 11{\cdot}0392 = {\cdot}5370$. This is the value of the reversion of $1l.$; consequently, $5000l. \times {\cdot}5370 = 2685l.$ is the sum which *B.* should receive for his reversionary interest.

When the reversionary benefit consists of an annuity to commence upon the death of an individual, and to continue for a term of years certain, its value is found by computing the value of the annuity for the assigned period, and proceeding as in the above example; but when it consists of an annuity commencing upon the death of one individual, and terminable upon the death of another, it becomes necessary to have recourse to tables of annuities on joint lives. Thus, if *A.* becomes entitled upon the death of *B.* to an annuity of $1l.$ for the remainder of his life, the present value of the reversion, or of *A.*'s interest, is equal to B — A B; where B denotes the present value of the annuity on the life of *B.*, and A B the value of the annuity on the joint lives of *A.* and *B.*, that is, to continue only so long as both remain alive.

The four following rules give the solution of all the cases of reversionary annuities which can arise when three lives are concerned, and it is seldom that a case occurs in practice involving a greater number. It is to be observed, that the two letters A B standing together denote, as above, the value of an annuity on the joint lives of *A.* and *B.*, B P that of an annuity on the joint lives of *B.* and *P.*, A P Q that of an annuity on the joint continuance of the three lives *A.*, *P.*, *Q.*, and so on. Let R be the value of the reversionary annuity in each case.

1. On a single life *A.*, after the longest of two lives *P.* and *Q.*; $R = A - AP - AQ + APQ$.
2. On the longest of two lives *A.*, *B.*, after a single life *P.*; $R = A + B - AB - AP - BP + APB$.
3. On a single life *A.*, after two joint lives *P.*, *Q.*; $R = A - APQ$.
4. On two joint lives *A.*, *B.*, after a single life *P.*; $R = AB - ABP$.

When reversionary benefits are contingent on lives failing in an assigned order, as for instance an annuity to be received upon the death of *A.* provided he die while *B.* is living, the formula becomes more intricate, and could scarcely be explained without entering into details inconsistent with the nature of this work. For full information on the subject, see the Treatises of *Baily* (1813), and *Milne* (1816). We may remark, however, that the formulæ for the solutions of questions connected with this subject may be greatly simplified by the use of an appropriate notation: for examples of which see *De Morgan's Essay on Probabilities, Cabinet Cycl.*; and *Hardy's New and General Notation for Life Contingencies* (1840); in which last work the solutions of all the cases of annuities and assurances which can arise, when not more than three lives are concerned, are arranged in a convenient table.

REVE'TEMENT. In Fortification, a strong wall of brick or stone built round the lower part of the rampart, to support the earth and prevent it rolling into the ditch, as well as to increase the difficulty of escalade.

REVIEW. The name now commonly assumed, by literary usage, for periodical publications consisting of a collection of critical essays. The *Journal des Savans*, commenced at Paris in 1665 by M. de Sallo, is commonly cited as the first review properly so called. The most distinguished modern journals under the name of review in France are, the *Revue Encyclopédique*, the oldest of them (now extinct); the *Revue Française*, and *Des Deux Mondes*; and the *Revue Britannique*, which consists of translations from the English. In England the *Monthly Review* (established in 1749) was the first publication of its kind. The establishment of the *Edinburgh Review* in 1802, followed by that of the *Quarterly* in 1809, may be said to have commenced a new era in criticism: from that time reviews have been adopted as the organs for conveying the opinions of sects and parties in religion and politics, as well as in literature. All the leading works of this description (the *Edinburgh*, *Quarterly*, *Foreign Quarterly*, *British and Foreign*, *Westminster*, *British Critic*, *Church of England*, and *Dublin*) now appear quarterly, or nearly so. The management of reviews in England is in the hands of an editor; whose name, however, does not appear, the publisher being the party responsible. The articles are also always anonymous: the *Westminster* only, some time ago, adopted the practice of putting the initials of contributors, or initials assumed by them, at the foot of their papers. All these reviews adhere to their designation, the articles admitted being in the form of *reviews* on some work or works specified at the head, although, in point of fact, the latter are often not even noticed by the reviewer, his remarks being more in the form of a general essay than of a review. In this way they serve the purpose of affording governments or political parties the means of making statements of facts, or declarations of opinion, which do not involve them in the difficulties of direct responsibility, and yet are generally understood to convey their sentiments. The pay of writers in reviews is various, depending not only on the means of the review, but on the rules adopted by particular editors; for some have thought proper to equalize their rate of remuneration, others to retain in their own hands the power of estimating contributions according to their supposed value. The French "revues" are conducted on a different plan. Articles in general have the name of the contributor attached; and the form of a "review" is not preserved, tales, poetry, essays on the politics of the day, &c., being admitted indiscriminately.

But besides France and England, reviews have been long established in the other European states, and in America; but this species of publication has taken the deepest root in Germany, where reviews may be said, without exaggeration, to appear daily, though none of them possess the influence of our *Edinburgh* or *Quarterly Review*. The *Göttinger Gelehrte Anzeige*, which is the oldest, still exists, and maintains a high character for ability and impartiality.

REVIEW. In Military language, an inspection of the appearance and regular disposition of a body of troops assembled for that purpose.

REVISE. *See* CORRECTING.

REVI'VOR, BILL OF, in Law, is a continuance of an original bill in a court of equity, when by death some party to it has become incapable of prosecuting or defending a suit, or a female plaintiff has incapacitated herself by marriage from suing alone. A bill "of revivor and supplement" continues a suit upon an abatement, and supplies defects arisen from some event subsequent to the institution of the suit.

REVOCA'TION, POWER OF. In Law, a power contained in a voluntary deed of conveyance to uses, by which the grantor retains the liberty to revoke the uses granted by the deed. Voluntary estates made with power of revocation are held fraudulent under stat. 27 Eliz. c. 4. as against purchasers.

RE'VOLUTE. (Lat. revolvo, *I roll back.*) In Zoology, when a part is rolled outwards or backwards.

REVOLU'TION. In Politics, a word of somewhat indefinite meaning, but usually denoting an extensive change in the political constitution of a country accomplished in a short time, whether by legal or illegal means. The term *Revolution*, in English History, is applied by way of eminence to the year 1688, universally regarded as the great era of English liberty,—when William III. and Mary acceded to the throne on the forced abdication of James II.

REVOLUTION. In Geometry, the motion of a point or line about a centre.

REVOLUTION, in Astronomy, is used to signify the period in which a planet, satellite, or comet returns to the place in its orbit from which we estimate its setting out.

REVOLUTION, FRENCH (ERA OF THE). In Chronology, this was substituted for the Christian era in all public acts and documents, by a decree of the National Convention in 1793; and fixed at the 22d September, 1792, the day of the foundation of the French republic. It was abolished by Napoleon, and the Christian era restored in 1806.

REX SACRO'RUM. In Roman History, a priest appointed after the expulsion of Tarquin to superintend certain holy rites which had always been performed by the king in person. (*Liv.* ii. 2.)

RHABDOLO'GIA. (Gr. ῥαβδος, *a rod*, and λογος, *a description.*) The name given by Napier to a method of performing multiplication and division by means of a set of figured rods or scales. *See* NAPIER'S RODS.

RHA'BDOMANCY. (Gr. ῥαβδος, and μάντεια, *prophecy.*) Properly, divination by a rod or wand. Some persons have been believed to be endowed by nature with a peculiar sense or perception, by which they are enabled to discover things hid in the earth, especially metals and water. But a more prevalent opinion has been, that the discovery of these substances might be effected by means of a divining rod. The divining rod is a branch of a tree, generally hazel, forked at the end, and held in a particular way, by the two ends, in the hands of the adept; and is supposed to indicate the position of the substance sought by bending towards it with a slow rotatory motion, the adept, according to modern practice, being placed in contact with some metallic or other magnetic substance. The art is said to be occasionally practised in the south of France and Italy, under the names of metalloscopy, hydroscopy, &c. Campetti, an Italian, in the beginning of the present century, excited much attention by his professed powers of rhabdomancy.

RHAMNA'CEÆ. (Rhamnus, one of the genera.) A natural order of arborescent or shrubby Exogens, inhabiting all parts of the world excepting the arctic regions. The berries of various species of *Rhamnus* are violent purgatives; while the fruit of some, as the jujube, is harmless and eatable. *Rhamnus trangula* yields the best kind of charcoal for gunpowder. From the berries of *R. infectorius* and others a yellow dye is obtained, but in general the species are neither useful nor ornamental. They are all small-flowered polypetalous or apetalous plants, with four or five stamens alternating with the lobes of the calyx.

RHAMPHA'STOS. (Gr. ῥαμφος, *a beak.*) The name of a genus of Scansorial birds (*Toucans*) in the system of Cuvier, distinguished by an enormous beak, nearly as thick and as long as the body in some species. The compensation by which this disproportionate beak is rendered manageable and portable is an extremely light and cellular structure internally. It is arcuated near the extremity, and in old toucans is irregularly indented along the edges. The toucans are distinguished from the hornbills by the scansorial modification of their feet, in which two toes behind are opposed to two in front; and by their long, narrow, and ciliated tongue. They are confined to the hot climates of America, where they live in small flocks, feeding on fruit, insects, and the eggs and callow offspring of other birds.

RHAPO'NTICIN. A substance obtained from the *Rheum rhaponticum* in the form of yellow scales; insoluble in cold water and in ether, and tasteless and inodorous. It dissolves in 24 parts of boiling water, and in 2 of absolute alcohol.

RHA'PSODIST. (Gr. ῥαπτω, *I sew or string together;* ᾠδή, *a song.*) A class of persons who are said to have flourished in the age of Homer, whose occupation it was to compose or commit to memory poems, which they recited for the amusement of their auditors. It has been supposed that by means of persons of this class the poems of Homer were preserved till the invention of writing secured them more permanently, and among them is divided the honour of the authorship of the *Iliad* and *Odyssey* by those who deny the individuality of Homer. But the fact of the existence of such a class with higher pretensions than to the faculty of making short extemporaneous effusions is highly doubtful, as it rests mainly on the assumed fact that the art of writing was unknown in Ionia in the Homeric age.

RHEA. (Gr. ῥεω, *I flow.*) In Classical Mythology, daughter of Cœlus and Terra, wife of Saturn, and mother of Vesta, Ceres, Juno, Pluto, &c. She is frequently confounded with Ops, Terra, and Cybele. For the particulars of her history, see SATURN.

RHEA. The name of a genus of Struthious birds, of which the three-toed ostriches of South America are the representatives.

RHE'IN. An inodorous bitterish substance of a yellow colour, obtained by gently heating powdered rhubarb with 8 parts of nitric acid of the sp. gr. 1·37, evaporating to the consistence of syrup, and diluting with cold water.

RHE'TORIC. (Gr. ῥητορική, sc. τέχνη, *the rhetorical art;* from ῥητωρ, *an orator.*) In the widest sense in which the word is occasionally used by modern writers, the art of prose composition generally. In the most restricted and most etymological sense, the art of oratory, or of addressing public assemblies. In an intermediate sense, in which, perhaps, it is most commonly employed, the art of

argumentative composition. This comes nearest to the signification which Aristotle, the earliest extant writer of a formal treatise on rhetoric, attached to the title of his subject, when he defined it to be the art of discovering and employing topics of persuasion. He arranged these topics or means of persuasion under three heads. First, those which arise from the character of the orator himself; *i.e.* the character in which, by what must be termed rhetorical artifice, he places himself before his hearers. It is obvious that a speaker addressing an assembly, who is known by them to be actuated by honest motives, and to understand the subject on which he speaks, advances by the mere possession of these adventitious attributes a long way towards the end and aim of oratory, viz. persuasion. Hence it is that Aristotle presents, as one of the chief branches of rhetoric, the art by which the speaker or writer, as it were, invests himself with these attributes, and thus ensures a more favourable reception to his argument. The art of moving the passions by the use of such arguments and representations as are proper to excite each belongs also, in Aristotle's arrangement, to this division of his subject. In his second division he treats of argument itself, considered with respect to its cogency or inconclusiveness in point of form; and hence logic, in this point of view, becomes ancillary to, or a subdivision of, rhetoric. The third division of the subject exhibits the modes of persuasion arising from style, arrangement, delivery, and action; and to this third branch writers who have treated of rhetoric in its more limited sense have usually confined themselves.

As the work of Aristotle is the first, so it is the only systematic treatise on rhetoric which the ancients have left us, among whom the art was much more diligently cultivated than among the moderns. Public speaking was of infinitely greater importance in the classical commonwealths than in any modern state; even in our own, where most sedulously studied and most valued, it is but a subsidiary accomplishment. The true momentum of decision, that which convinces or dissuades, lies in the pen of the writer, rather than the voice of the orator; and whilst in the Grecian republics assemblies were actually swayed by oratory to determine on a particular course of action, its principal use now appears to be to arraign, to vindicate, or to explain the actions of individuals. French oratory, from the nature of its subject, is and always was confined within narrow limits. Probably pulpit oratory, in modern European society, answers most nearly to the classical notion of rhetoric; and, had it ever been subjected to systematic rules, would have been found most nearly to conform to those which the ancients have left us. Among the Romans, oratory did not begin to be cultivated as a science until just at the period when its political importance was about to cease. Rhetoric, under the Roman empire, was taught as a regular science; but its practical display was confined to the orators of the forum, among whom the art gradually declined, from the tendency of the civil law, during the last period of its development, to conduct all process by written rather than oral method. On the other hand, the rules of rhetoric were applied to the construction of declamations, a species of fictitious argument much in vogue during the decline of Roman literature; and of panegyrical harangues. The study of rhetoric, in this perverted sense of the word, *i.e.* of declamatory speaking or writing, found peculiar favour in the African and oriental schools of the Roman empire. Some of the early Christian writers, especially Tertullian, afford evident tokens of having acquired the art of composition under such discipline. *See* ELOQUENCE.

RHEU'MATISM. (Gr. ῥευματισμος.) A painful affection of the joints, attended by swelling or stiffness; and also affecting the muscular, tendinous, and fibrous textures. It is occasionally accompanied by fever, when it constitutes *acute rheumatism*, or *rheumatic fever;* in which case the joints are much swollen and excessively painful; the pulse frequent, but seldom hard; the perspiration usually abundant and acid; the tongue extremely foul, and the bowels costive; headach is seldom complained of, and delirium very rare. In this form of the disease its translation or metastasis to the heart is not uncommon. The treatment consists in occasional venesection; in the use of purgatives and sudorifics, and occasionally of tonics, more especially cinchona: calomel and opium are also largely, and often very successfully employed. *Chronic rheumatism* is not in general attended by any very remarkable constitutional symptoms. It occasionally leads to permanent distortion of the joints; affects the periosteum, tendons, and ligaments; and is most common in debilitated habits, when the health has been broken by previous disease or over exertion of body or mind. Opium, especially in the form of Dover's powder, is generally necessary in this disorder to procure rest. The bowels should be kept moderately active by warm purges, and tonics and alteratives cautiously administered. A course of sarsaparilla is often extremely serviceable: colchicum has been resorted to, but with most uncertain success.

RHINO'CEROS. (Gr. ῥιν, *a nose;* κεϱας, *a horn.*) The name of a genus of Pachydermatous mammals, characterized by one or two horny productions upon the nose. A species of hornbill is also called rhinoceros, on account of the remarkable recurved horny process which rises from its upper mandible.

RHINSBURGERS. The name of a sect of Christians which sprung up in Holland in the 18th century. They seem to have separated from the church for the mere sake of separation, for they held all its doctrines, but rejected all discipline; no other profession being required from its members than a belief that Christ is the Messiah, and that the scriptures are inspired. They allowed of no priests: any member (women alone excepted) might preach and expound in their meetings, which were held in so called *colleges of piety.* At one period they had formed eighteen of these in different towns; but from the large licence of the interpretation of scripture which they enjoyed, several ran into enthusiasm, and having no principle of cohesion they soon fell to pieces, and are now completely extinct. *See* SOCIETY.

RHIPI'PTERANS, *Rhipiptera.* (Gr. ῥιπις, *a fan;* πτεϱον, *a wing.*) A name proposed by Latreille to supersede that of *Strepsiptera,* by which Kirby designated a new order of insects which he had discovered. The new name has nothing to recommend it, since it signifies a character, founded on the presence of pterygoda, common to other orders of insects, as the Lepidopterans.

RHIZA'NTHEÆ. (Gr. ῥιζα, *a root;* ανθος, *a flower.*) A class of plants occupying a station between sexual and asexual species, and appearing to be an intermediate form of organization between Endogens and the lower orders of vegetation. They agree with the former in the presence of sexes, and in their flowers having sometimes a ternary structure; but they have scarcely any spiral vessels; and their seeds appear, as far as they have been examined, to consist of a mass of spores, without a special embryo. In their succulent texture, in their colour, often in their putrid odour when decaying, in the sporuliferous seeds, and in their parasitical habits, these plants resemble *Fungaceæ;* while in their flowers and sexes they accord with *Araceæ,* or similar Endogens. They are in all cases parasites, and destitute of proper leaves, in lieu of which some of them have scales imbricated over their stems. Notwithstanding their parasitical habits, some are of extraordinary size: the flowers of *Rafflesia arnoldi* are as much as nine feet in circumference.

RHIZO'MA. In Botany. *See* ROOTSTOCK.

RHI'ZOSTOMES, *Rhizostoma.* (Gr. ῥιζα, and στομα, *a mouth.*) A genus of *Medusæ,* including those which have the absorbing orifices of their nutrient canals of small size, and situated in great numbers on the branches of arms, or peduncles, extending from the centre of the inferior surface of the disk.

RHO'DIUM. (Gr. ῥοδον, *a rose;* on account of the rose-red colour of some of its salts, especially of the chloride, when dissolved in water.) A metal discovered in 1803, by Wollaston, associated with palladium in the ore of platinum. It is of a whitish colour, very difficult of fusion, and very hard. Its specific gravity is about 11, and its equivalent about 52. It has been used for the points of metallic pens.

RHO'MBOID. In Geometry, a quadrilateral figure which has its opposite sides equal. When its angles are right angles, it is called a *rectangle.*

RHOMB SPAR. A crystalline magnesian carbonate of lime.

RHO'MBUS. In Geometry, a plane figure bounded by four equal straight lines. When its angles are right angles, it becomes a square.

RHONCUS. (Gr. ϱογχος.) A rattling or wheezing sound: the term is chiefly applied to sounds occasioned by certain morbid states of respiration, as indicated by the stethoscope.

RHU'BARB. The root of the *Rheum palmatum,* and perhaps some other species, cultivated in China for the supply of the drug market. The varieties of rhubarb known in commerce under the names of Russian, Turkey, and Indian rhubarb, are all derived from one source; but the select pieces are sold under the name of Russian and Turkey rhubarb, and those of somewhat inferior quality as East Indian. To judge of the quality of rhubarb, it should be cut or broken; when good it is of a mottled reddish or brownish red colour; that which is very pale or very dark coloured, and either so soft as to be spongy, or hard and stony in texture, is bad. Rhubarb is a valuable article of the materia medica, being an aperient, and at the same time a tonic and astringent. The average dose of powdered rhubarb is twenty grains, which after its purgative operation leaves a certain astringent effect upon the bowels; hence its use in diarrhœa: from two to five grains operates as a tonic, and is very useful in some forms of dyspepsia. A mixture of one part of rhubarb with two of powdered sulphate of potash is an excellent aperient for children. It is occasionally given as a tincture or infusion; but the powder is the best form, either in a little plain, or peppermint, water, or in the form of pill.

RHUMB. A circle on the earth's surface making a given angle with the meridian of the place, marking the direction of any object through which it passes. The divisions on the compass card are called rhumbs. *See* MERCATOR'S CHART.

RHUMB LINE. In Naval Affairs, the track of a ship which cuts all the meridians at the same angle; called also the *loxodromic curve.* This being the simplest curve, is the route universally pursued; but a ship sailing on this curve never looks direct for her port until it comes in sight. *See* LOXODROMIC CURVE.

RHYME. (Gr. ῥυθμος, *measure;* or Germ. reim.) In Poetry, the correspondence of sounds in the last words or syllables of verses. The latter is the true rhyme of modern European languages. There are rhymed verses in the Latin classical poets, where the jingle seems intentional, and more distinct examples of it in the fragments of Roman military songs, &c., which have come down to us. But in the earlier period of the decay of the Latin language, when accent was substituted for metre in the rhythmical arrangement of the verse, rhyme made its way into the composition of church hymns, &c. It has been attempted, but with little success, to deduce this innovation from the Goths, and from the Arabians; but the former, like the old Teutonic races, probably used alliteration, but no rhyme in their verses; and the latter could not have influenced European literature until a period long after that in which rhyme first appears. A rhyme in which the final syllables only agree (*strain, complain*), is called a male rhyme; one in which the two final syllables of each verse agree, the last being short (*motion, ocean*), female; and the latter is sometimes extended in Italian poetry to three syllables (*femore, immemore*), when the verse is called *sdrucciolo.* In English such a licence is hardly permissible, except in burlesque poetry (see *Hudibras* and *Don Juan* for instances). By the strict rules of French prosody, the male and female species of rhymes must be alternately used, however intricate the disposition of the verse may be; although the last short syllable is generally mute, or very slightly sounded. Rhymes which extend not only beyond the three last syllables, but through the whole structure of the lines, are used in Arabian and Persian poetry. Rhymes in which the consonants of the last syllable in each verse are identical (*dress, address*) are vicious in English, but rather admired in French poetry. One more singularity of English poetry deserves notice: while from the irregularity of our spelling many syllables rhyme with each other, although widely dissimilar in orthography (*woo, pursue*), there are, on the other hand, rhymes which speak to the eye, and not to the ear; *i. e.* in which the orthography of the rhyming syllables is the same, but the pronunciation different; as, *wind, find; gone, alone.* In the following triplet of Dryden, —

> 'Tis nothing yet; then poor and naked come,
> Thy Father will receive his unthrift home,
> And thy blest Saviour's blood discharge the mighty sum,—

it will be seen that the first and third lines rhyme in a legitimate manner, although the last syllables are differently spelt; while the first and second rhyme to the eye only, and not to the ear. This is a licence only rendered admissible by precedent.

RHYNCHOPHORES, *Rhyncophora.* (Gr. ῥυγχος, *a beak,* and φερω, *I carry.*) The name of a family of Coleopterous insects, comprehending those which have the head prolonged in the form of a snout or proboscis.

RHYTHM. (Gr. ῥυθμος.) The consonance of measure and time in poetry, prose composition, and music, and by analogy in dancing. Each verse or each period may be considered as a whole, within which the poetical rhythm is regular and exact, within certain limited variations, the rhetorical less perfect, and the pleasure derived from it rather matter of taste and experience than of rule. Those parts which receive the ictus or stress of the rhythm are termed *arsis* (elevation), the remainder form the *thesis* (depression); the former is frequently denoted to the eye by the accent marked ′, when in a foreign or unknown word we wish to direct the voice in pronunciation to employ the correct emphasis. The smallest rhythmical division is the foot, by which every union of arsis and thesis is understood. A short syllable is an original unit of time; a long syllable contains two units. The number of feet enumerated in classical writers on metre amount to twenty-eight, including all the varieties which may be formed out of two, three, or four syllables, long and short, and varying from two to eight units of time. *See* FOOT, METRE.

RIAL. A gold coin current in the reigns of Henry VI. and Elizabeth: under the former its value was 10*s.*, under the latter 15*s.*

RIBS. In Architecture, curviform timbers to which, in an arched or coved plaster ceiling, the laths are nailed.

RIBS. A term for the timbers of a ship which spring from the keel, as the ribs of an animal from the back bone.

RIBS. In Anatomy, the lateral appendages of a vertebra, especially when developed so as to encompass the trunk. In the human subject there are twelve ribs.

RICE. *See* ORYZA.

RICE PAPER. This substance is said to be a membrane of the *Artocarpus incisa,* or bread-fruit tree. (*See* ARTOCARPEÆ.) It is brought from China in small pieces, dyed of various colours, and is used as a material for painting upon, and for the manufacture of several fancy and ornamental articles. It is sometimes erroneously stated to be prepared from rice. (See Brewster, *Edinb. Journ. of Science,* vol. ii.)

RICI′NIC ACID. One of the products obtained by distilling castor oil at a high temperature.

RICKETS. *See* RACHITIS.

RICOCHE′T FIRING, in Gunnery, is a mode of firing with small charges from pieces of ordnance elevated at small angles, as from 3° to 6°. It is a very destructive method; as the rebound causes the shot or shell to pass along a great space almost upon the ground, destroying all that it meets with in its way. The word signifies, literally, the sort of motion which is familiarly called ducks-and-drakes, as applied to a flat stone thrown on the surface of the water under a very small angle.

RIDEAU. In Fortification, a small elevation of earth extending itself lengthwise on a plain, serving to cover a camp from the approach of the enemy, or to give other advantage to a post.

RI′DER. A term used to signify any addition to manuscripts or other documents, inserted after their completion.

RIDGE. In Architecture, the upper horizontal timber in a roof, against which the rafters pitch.

RI′DING. The three divisions of the county of York are so termed, by a corruption of the Saxon word *trilhing* or *triding* (third part).

RIDO′TTO. (Ital.) A favourite public Italian entertainment, consisting of music and dancing; held generally on fast eves.

RI′FLE GUNS. Muskets or pieces of ordnance, whose barrels, instead of being a clear cylinder inside, are furrowed with spiral channels. The object is to give the ball a rotatory motion about an axis, in consequence of which it preserves its direction with much greater certainty than when fired from the common clear barrel. *See* GUN.

A body of men armed with rifles are called riflemen; but the term is most frequently applied to the military corps called the *rifle brigade,* and to the 60th regiment of the British army, which is dressed in green and armed with rifles.

RIG. The peculiar manner of fitting the masts and rigging to the hull of any vessel; thus schooner rig, ship rig, &c., imply the masts and sails of these vessels without regard to the hull.

RI′GGING. The system of cordage by which the masts are supported, and the sails extended or taken in. The rigging is hence divided into *standing rigging* and *running rigging.* The standing rigging consists of the *pendants,* short strong ropes first put over the lower mast heads, and having thimbles for hooking tackles to; the *shrouds, stays,* and *backstays.* The lower rigging implies that of the lower masts, the topmast rigging that of the topmast, and so on. The size, strength, number of ropes, &c. of the rigging, are all matters determined by experience. A complete description of rigging is to be found in the well-known work of Darcy Lever.

RI′GGING LOFT. The room or rooms in which the rigging is prepared.

RIGHT. In Geometry, a term sometimes used synonymously with straight, as *right line;* but generally as opposed to oblique. Thus, a *right angle,* the angle formed by two straight lines perpendicular to each other, or an angle of 90°; *right cone, cylinder, prism, pyramid,* &c., figures whose sides are perpendicular to the plane of the base.

Right-angled Triangle. A triangle having one right angle.

Right-angled Triangle. In Numbers. A favourite speculation of the Platonic school of mathematicians was to find rational numbers which should designate the sides of a right-angled triangle. Pythagoras gave the formulæ n, $\frac{n^2-1}{2}$, and $\frac{n^2+1}{2}$, where n is odd. Plato gave $2n$, n^2-1, and n^2+1, where n is either odd or even. Various other forms have been given by subsequent writers. The determination of such sets of formulæ forms a branch of the Diophantine Analysis.

RIGHT SPHERE. In Geography, the position of the sphere when the equator cuts the horizon at right angles.

RIGHT ASCENSION, in Astronomy, is the angle at the pole of the equator formed by two great circles, one of which passes through the first point of Aries, and the other through a celestial body, and is consequently measured by the arc of the equator intercepted between those circles. *Right ascension* and *declination* are the

two co-ordinates to which the positions of celestial objects are referred.

RIGHT, DIVINE. *See* DIVINE RIGHT.

RIGHT OF PRO'PERTY. (Lat. jus proprietatis; Fr. droit de proprieté.) In Political Economy, the right which states, bodies of individuals, and individuals have to the exclusive use and enjoyment of such lands, natural powers, and products as have been appropriated or set apart for any peculiar purpose.

Origin of this Right. — It would occupy the reader's time to no good purpose were we to state the different theories that have been advanced by jurists and writers on public law to account for the origin of this right.* This, indeed, appears to us to be sufficiently obvious. All the rude products furnished by nature have to be appropriated; and not one in a thousand, perhaps, of these products is, in its natural state, capable either of supplying our wants or administering to our comforts. Hence the necessity not only of applying labour in the appropriation of natural products, but in fashioning and preparing them so as to be useful; and hence, also, the origin of the right of property.

If a number of individuals be set down together on the shore of an unoccupied and unappropriated island, abounding with natural products, such as game, trees laden with fruit, &c., each will have quite as good a right as another to take the game or the fruit. But those who do so, or who have through their skill and industry appropriated a portion of the common stock, will obviously be entitled to the exclusive use of such portion. We shall not undertake to decide whether there be or be not a principle inherent in man that at once suggests to every individual that it is his duty not to interfere with what has been produced or appropriated by the labour of others; it is sufficient for us to know that the briefest experience would point out to every one the necessity of respecting this principle. If A. climb a tree and bring down fruit which as soon as he comes to the ground is taken from him by others, he will not again engage in any similar undertaking till he be well assured that he shall be permitted exclusively to profit by what has been obtained through his sole exertions; nor will others engage in any such undertaking without a similar assurance. No doubt, therefore, the right of property has had a very remote origin. The necessity for its establishment is so very obvious and urgent, that it must have been all but coeval with the formation of societies. All have been impressed with the reasonableness of the maxim which teaches that products acquired by the *labour* of a man's body, and the *work* of his hands, should be considered as exclusively his own. Even among the rudest savages the principle of *meum* and *tuum* is recognized; the bows and arrows of the huntsman, and the game he has killed, being regarded by him as his own, and his right to their exclusive possession being respected by his fellows. The right of property, like other rights, is, no doubt, perfected only by degrees, and is necessarily limited and adapted to the state of society at the time. Thus, among hunters, the *feræ naturæ* on which they subsist, not being bred under the care or inspection of individuals, are, so long as they run wild in the forest, the common property of the tribe, and only become the property of individuals after they have been appropriated or caught by their labour or ingenuity. As society advances, the right of property expands. The modern Tartars, like the ancient Scythians, estimate their wealth by the number of their cattle. Their right to the animals which they have domesticated and reared is deemed sacred and inviolable; but the pasture grounds belong, like the hunting grounds of the Indians, to the whole society; and as the flocks are driven from one place to another, the grounds may be successively depastured by the cattle of every different individual. The moment, however, that men began to renounce the pastoral for the agricultural mode of life, a right of property in land began to be established. The soil cannot be cultivated, its fertility cannot be increased, nor can it be made to produce those crops which yield the largest supplies of food and other necessary accommodations, without continuous labour, and persevering attention.

> ——— Pater ipse COLENDI
> Haud facilem esse viam voluit.

Hence the origin of property in land. Nothing, it is plain, could ever tempt any one to engage in a laborious employment; he would neither domesticate wild animals, nor clear and cultivate the ground, if, after months and years of toil, when his flocks had become numerous, and his harvests were ripening for the sickle, a stranger were allowed to rob him of the produce of his industry. The utility, or rather necessity, of enacting some general regulations, that should secure to every individual the peaceable enjoyment of the produce he had raised, and of the ground he had cultivated and improved, is, indeed, so very obvious, that it suggested itself to the first legislators. The author of the Book of Job places those who removed their neighbours' landmarks at the head of his list of wicked men; and the early Greek and Roman legislators placed these marks under the especial protection of the god Terminus, and made their removal a capital offence. (*Goguet, de l'Origine des Loix*, lib. i. art. 2.) Society may, in fact, be said to have grown out of the institution of a right of property in land. "Had not," says Mr. Justice Blackstone, "a separate property in lands, as well as moveables, been vested in some individuals, the world must have continued a forest, and men been mere animals of prey. Whereas now, so graciously has Providence interwoven our duty and our happiness together, the result of the institution of property has been the ennobling of the human species, by giving it opportunities of improving its rational faculties, as well as exerting its natural. Necessity begat property; and in order to insure that property recourse was had to civil society, which brought along with it a long train of inseparable concomitants, — states, government, laws, punishments, and the public exercise of religious duties. Thus connected together, it was found that a part only of society was sufficient to provide, by their manual labour, for the necessary subsistence of all; and leisure was given to others to cultivate the human mind, to invent useful arts, and to lay the foundation of society." (*Comment.* book ii. cap. 1.)

It is obvious, from what has now been stated, that the law of the land is not, as Dr. Paley has affirmed, the real foundation of the right of property. It has a much more remote and more solid foundation. It grows out of the circumstances under which man is placed; and could not be overthrown or set aside without depopulating the earth, and throwing mankind back into primæval barbarism. The obvious utility of securing to each individual the peaceable enjoyment of the land he has enclosed and cultivated, and of the produce raised or acquired by his labour, has undoubtedly formed the irresistible reason that has induced every people to make the right of property a part of the law of the land, and to guard it by the strongest sanctions. The security of property is, in truth, the principal foundation on which society rests. Until property had been publicly guaranteed, men must have looked on each other as enemies rather than as friends. The idle and improvident are always desirous of seizing on the earnings of the laborious and frugal; and if they were permitted to prosecute their attacks, they would, by generating a feeling of insecurity, effectually check both industry and accumulation, and sink all classes to the same level of hopeless misery as themselves. The security of property is, if possible, still more necessary to accumulation than to production. No man ever denies himself an immediate gratification, when it is within his power, unless he think that, by doing so, his present forbearance will obtain for him a greater accession of comforts and enjoyments, or that it will obviate some probable and considerable evil at a future period. Where the right of property is vigilantly protected, an industrious man who gains as much by one day's labour as is sufficient to maintain him two is not idle the second day, but accumulates the surplus produce above his wants as a capital; the increased consequence and enjoyments which the possession of capital brings along with it being, in the great majority of cases, more than sufficient to counterbalance the desire of immediate gratification. But, wherever property is insecure, we look in vain for the operation of the principle of accumulation. "It is plainly better for us," is then the invariable language of the people, "to enjoy while it is in our power, than to accumulate property which we shall not be permitted to use, and which will expose us to the depredations of those who exist only by the plunder of their more industrious neighbours."

The security of property is violated not merely when a man is deprived of the power of peaceably enjoying the fruits of his industry; it is also violated, and perhaps in a still more unjustifiable manner, when he is prevented from using the powers with which nature has endowed him in any way, not injurious to others, he may consider most for his own advantage. Of all the species of property which a man can possess, the faculties of his mind and powers of his body are most particularly his own. He should, therefore, be permitted to enjoy, that is, to use or exert, these powers at his discretion. And hence the right of property is as much infringed upon when a man is interdicted from engaging in a particular branch of business, as it would be were he unjustly deprived of the produce he had raised. Every monopoly which gives to a few individuals the exclusive power of carrying on certain branches of industry is thus, in fact, established in direct violation of the property of every one else. It prevents them from using their natural capacities, or powers, in the manner they may consider best; and as every man who is not a slave is justly held to be the best, and indeed only judge, of what is advantageous for himself, the principles of natural law

* The learned and curious reader may consult Puffendorff, lib. iv. s. 1—6.

and the right of property are both subverted by his exclusion from any employment. In like manner, the right of property is violated when regulations are made to force individuals to employ themselves or their capital in a particular way. The property of a landlord is violated if he be compelled to adopt any system of cultivation, even supposing it were really preferable to that which he was previously following. The property of the capitalist is violated when he is obliged to accept a lower interest for his stock than he might have obtained; and the property of the labourer is violated whenever he is obliged to engage in any particular occupation. It follows, too, that every restraint on the freedom of commerce is an infringement of the right of property. If I, the lawful owner of any given article, am prevented from exchanging for any other I may be desirous to obtain, the right of property is as much invaded as if I were debarred from making any direct use of the article. Had this circumstance been adverted to, it is probable the restrictive system would not have made quite so much progress as it has done.

Effects of the Insecurity of Property. — The finest soil, the finest climate, and the finest intellectual powers, can prevent no people from becoming barbarous, poor, and miserable, if they have the misfortune to be subjected to a government which does not respect and support the right of property. All those vast and fruitful countries, comprising the fairest portion of the earth, that stretch from the Black Sea to the Persian Gulph, and from the western shores of Morocco to the confines of China, once the seat of the most renowned empires, of arts and civilization, are now, through the want of security and freedom, become the most deplorable spectacles of extreme misery. "No care," says Mr. Kinneir, speaking of some of the most fertile provinces of Asia Minor, "is taken to improve the land; nor can this be matter of surprise, when we reflect that the farmer is liable to be turned out at a moment's warning, and is certain of being taxed, or rather plundered, in exact proportion to the yearly produce of his farm. It is not, indeed, uncommon, should there be a prospect of a plentiful harvest, for the crops upon the ground to be seized by the pacha, at a low valuation, and then put up to the highest bidder!" (*Journey in Asia Minor, &c.* p. 52.) The same intelligent traveller observes, in speaking of Syria, "that the Grand Seignior is the lord of the soil, and the *miri* or capitation tax, is regularly paid into the public treasury. The pachas derive their revenues from levying arbitrary contributions in money and in kind upon the merchants, citizens, villagers, and cultivators of the land. This unjust and uncertain mode of taxation is rendered still more afflicting by the manner of collecting it. The troops and followers of the pacha, a licensed banditti, disperse themselves over the country and villages, where they live at free quarters, and for every piastre that is received by their master at least three have been exacted from the unfortunate proprietor. Under such a system neither agriculture, commerce, arms, arts, nor sciences, can ever make the least progress; and it is deeply to be lamented that no successful effort has hitherto been made to wrest so noble a country from those who are so unworthy to possess it." (*Ibid.* p. 174.)

Had it been possible for arbitrary power to profit by the lessons of experience, it must long since have perceived that not only the wealth of its subjects, but its own, would be most effectually increased by maintaining the security of property. Were the governments of Turkey and Persia to establish a vigilant system of police, to secure to each individual the unrestrained power of disposing of the fruits of his labour, and to substitute a regular plan of taxation in the room of the present odious system of extortion and tyranny, industry would gradually revive; capital and population would be augmented; and a moderate land-tax, or reasonable duties on a few articles in general demand, would bring a much larger sum into the coffers of the treasury than all that is now obtained by force and violence. The *stated* public burdens laid on the Turks, Persians, &c., are light compared with those imposed on the English, Dutch, and French. But the latter know that when they have paid the taxes due to government they will be permitted peaceably to enjoy or to accumulate the residue of their wealth; whereas the subjects of eastern despotisms have, generally speaking, no security that, the moment after they have paid their stated contributions, the pacha, or one of his satellites, may not strip them of every additional farthing they possess! Security is the foundation, the principal element, in every well-digested system of finance. When maintained inviolate, it enables a country to support, without much difficulty, a very heavy load of taxes; but where there is no security, where property is a prey to rapine and spoliation, to the attacks of the needy, the powerful, and the profligate, the smallest burdens are justly regarded as oppressive, and uniformly exceed the means of the impoverished and dispirited inhabitants.

Power of bequeathing Property. — To perfect the right of property, it is necessary not only that an individual should have the power freely to dispose of it during his lifetime, but also that he should have power to bequeath it to others in the event of his death. *Nihil enim tam conveniens est naturali æquitate*, say the Roman jurists; *quam voluntatem Domini volentis rem suam in alium transferre, ratam haberi.* (*Instit.* lib. ii. tit. i. s. 40.) It is evident that the being enabled to bestow our property on those who occupy the chief place in our affections must have a powerful effect in stimulating industry. When a man is assured that he is not labouring for strangers, that the fruit of his industry will not fall into the hands of an unknown successor, but will descend to his children or his friends, he finds, as it were, his existence indefinitely extended, and continues with unimpaired energy to exert himself for the benefit of those who are to perpetuate his family and name, and whose welfare, perhaps, is as dear to him as his own. The power of bequeathing property connects the future with the present; without it, no undertaking would be entered upon which did not promise an adequate return during the lifetime of the projector. But in civilized societies the plans of the capitalist are not circumscribed by the brief duration of human life. He plants forests by which he can never expect to be enriched; he raises edifices fitted and intended to outlive many generations; and executes innumerable improvements, of which posterity alone can reap the benefit. And he does all this because he is permitted to name his successors; to transmit his property and effects to those with whom he is connected by the ties of kindred, affection, or gratitude, and in whose welfare he feels a deep interest.

Numerous difficult and important questions have, however, to be decided in framing regulations as to the bequeathing of property by will; and as our purpose at present is merely to point out the principle on which the power is conceded, we shall defer the notice of the conditions which should limit its exercise to the article SUCCESSION, LAW OF.

Property in Wild Animals. — It is clear from what has been previously stated, and from the nature of the thing, that nothing can be made property unless it be susceptible of appropriation; and, on this ground, it has sometimes been objected to the game laws, that they have made a property of that which being incapable of appropriation should belong to the community, or to the captors. In support of this view of the matter the rule of the Roman law has been appealed to, where it is laid down — *Feræ igitur bestiæ, et volucres, et pisces, et omnia animalia quæ mari, cœlo, et terra nascuntur, simul atque ab aliquo capta fuerint, jure gentium statim illius esse incipiunt; quod enim ante nullius est, id naturali ratione occupanti conceditur.* (*Instit.* lib. ii. tit. i. § 12.) But it is distinctly laid down in the same article whence we have borrowed this paragraph, that the proprietor of an estate has full power to prohibit any one from entering upon it to kill wild animals. Without this proviso, there would not, in fact, be any such thing as a real property in land; and this is, in truth, all that is meant when it is said that game is property. A partridge or hare is mine so long as it remains on my estate; but the moment it transfers itself to the estate of another, it becomes the property of the owner of such estate. Poachers are punished, not because they have killed wild animals, but partly and principally because in doing so they invade the right of property by killing it without leave on lands belonging to other parties, on which they had no right to enter, and partly because they have not paid the tax demanded by government from all who kill game.

It is sometimes indispensable for the interests of society to appropriate the whole or a portion of the landed property of one or more individuals to some public purpose, as the formation of a road, a canal, &c. But property should never be wantonly taken for such purposes, nor till the advantages to be obtained by its cession have been fully established before some competent tribunal; and when this has been done, full compensation should in every case be given to those who are thus called upon to give up their property for the promotion of the public interests.

Inconveniences of a Community of Goods. — Those schemes of policy that have been founded or projected either upon the principle of a communion of goods, or of an equal partition of the land among the different families belonging to the society, are bottomed on the most erroneous views, and would, if they could be acted upon, be an effectual bar to every improvement. Those who have advocated these schemes, struck with the evils arising from the violations of private property to which the ill-regulated cupidity of some and the wretchedness of others are perpetually giving birth, seem to have thought that the crimes and disorders that were thus occasioned might be advantageously and completely got rid of by abolishing the right of property, and obliging men to labour in common, and giving each in-

dividual an equal share of the produce raised by the joint labour of all. They imagined that they would, in this way, eradicate that selfishness which was so fruitful a source of mischief; that as no one could be either richer or poorer than his neighbour, no one would be the object of envy or attack; and that the principal sources of discord and crime being thus dried up, men would henceforth live together like brothers, and be anxious only to promote each other's welfare. But these expectations are wholly inconsistent with the nature of man, and cannot, therefore, be realized. We might as well attempt to eradicate the feelings of hunger, and of thirst, as of self-interest; and if we could eradicate it, we should eradicate the principle which impels man to labour, which prompts him to contrive, invent, and amass. There is plainly nothing blameable in our preference of ourselves to others. The desire of aggrandizement becomes injurious only when it prompts individuals to endeavour to advance their own interests by acting unjustly by their fellow-men; for, otherwise, it is the source of all that is most advantageous to society. And it is mainly for the purpose of obviating this abuse, and of protecting every one in the enjoyment of his property, that governments have been instituted. *Hanc enim ob causam*, says Cicero; *maxime ut sua tuerentur, respublicæ civitatesque constitutæ sunt. Nam etsi duce naturæ congregabantur homines, tamen spe custodiæ rerum suarum urbium præsidia quærebant.*

It is idle, therefore, to think that the feelings of self-interest can ever be eradicated from the human breast. All that the adoption of the system of those who propose to establish a communion of labour and of goods could do, would be to give the principle of selfishness a different direction from what it takes when left to itself; to render it a source of idleness and poverty, instead of labour and wealth. Suppose you have a community of a thousand individuals who live and labour in common: in this, as in all similar cases, it would be obvious to every individual that if, on the one hand, he made any unusual exertions, either of body or mind, he would reap only the thousandth part of the advantages derivable from them; while, on the other hand, it must be equally obvious, that if he contrive to avoid performing his due share of work, or obtain more than his fair proportion of its produce, he will be the *sole* gainer. Under such circumstances, it is clear not only that society could make no farther progress, but that it must gradually, and not very slowly, retrograde. The principle of self-interest would not be annihilated; on the contrary, it would be as strong as ever; but inasmuch as no one could henceforth expect to advance himself by industry, ingenuity, or frugality, a regard for his own interest would teach him to follow an opposite course, and would infallibly prompt him to labour as little and to consume as much as possible! The evils produced by such a system would be so intolerable that it could not be continued. But if it were, we should, instead of the industry, invention, and wealth produced by the establishment of private property, and the consequent efforts of individuals to advance themselves in the scale of society, have universal idleness, indifference, and the most abject misery. We should purchase an exemption from those crimes and disorders incident to an advanced stage of society, and which the adoption of good laws and a vigilant system of police go far to repress, by the annihilation of every thing that raises civilized man above the condition of the savage, and by subjecting all classes to the plague of universal poverty.

Inconveniences of Agrarian Laws. — The attempt to found a society upon an agrarian law, or upon the principle of maintaining an equal division of land amongst the different families of the society, is as much opposed to the nature of things as a communion of goods; but were the system in other respects as advantageous as it is the reverse, it could not be maintained for any considerable period. Though the first settlers of an unoccupied country were to adopt this plan, it would, in less than a dozen years, be wholly subverted, and there would be the greatest inequality in their fortunes. This would arise from differences of strength, talent, and conduct, from the varying numbers and conduct of children, and the other unforeseen accidents and occurrences which are always affecting the circumstances of individuals. It is absurd to suppose that an equality of condition could be maintained, notwithstanding the operation of such powerful causes of derangement, without resorting to the most atrocious system of tyranny, without equalizing the number of children, and abstracting a portion of the earnings of the industrious and frugal to bestow them on the idle and improvident. But it is unnecessary to dwell on such crude absurdities. The distinction of rich and poor is not, as some shallow sophists would seem to suppose, artificial, but real; it is as much a part of the order of Providence as the distinction of the sexes. It depends on the differences of the physical and mental powers and dispositions of different individuals, and of the different circumstances under which they happen to be placed; and to attempt to obliterate this distinction by encroaching on the right of property, and enacting agrarian laws, or laws of a similar tendency, is to attempt to accomplish what is in its nature impracticable, at the expense of great and certain mischief and inconvenience.

RIGHT, PETITION OF. A declaratory enactment passed by the parliament of 1628, to which this name was given by the framers, who were desirous to imply by it that the franchises therein specified were not newly acquired, and that the law was merely explanatory of the ancient constitution. It was calculated to protect the subject against forced loans, benevolences, taxes imposed without consent of parliament, arbitrary imprisonments, &c. Much delay and some evasion took place before Charles I. could be induced to give the royal assent to this measure.

RIGHTS, BILL OF. *See* Bill of Rights.

RIGI'DITY. In Mechanics, a resistance to change of form. In all theoretical investigations respecting the application of forces through the intervention of machines, those machines are assumed (except cords) to be perfectly rigid, so far as the forces employed are able to affect their integrity of form and structure. Rigidity is often, in the arts, called *stiffness*, and is opposed to flexibility.

The rigidity of cords, or the difficulty with which they are bent into any given curve, is the chief cause of the loss of power arising from their employment in machines. The law of their loss of force may be thus expressed: — The resistance arising from the stiffness of cords is as the weights which stretch the cords multiplied by the thickness of the cords, and divided by the radii of curvature of the surfaces over which they pass. It is, however, necessary to state that experiments exhibit great discrepancies with this theoretical law.

RI'GORISTS. In Ecclesiastical History, a name sometimes given to the extreme Jansenist party. (See *Mosheim*, vol. v. p. 221. transl. ed. 1790.)

RI'MOSE. (Lat. rima, *a cleft.*) In Zoology, when the surface of an animal or part resembles the bark of a tree, having numerous minute, narrow, and nearly parallel excavations, which run into each other.

RINFORZA'NDO. (It. *strengthening.*) In Music, a direction to the performer, denoting that the sound is to be increased. It is marked thus $<$; when the sound is to be diminished (*diminuendo*) this mark $>$ is used.

RING. In Geometry, the figure enveloping a sphere which moves with its centre always in a given curve, most commonly a circle. For the principal properties of this solid, see Hachette, *Géometrie Descriptive.*

The term is also sometimes applied to designate the area of the space between two concentric circles.

RING BONE. In Farriery, a callus growing in the hollow circle of the little pastern of a horse, just above the coronet.

RING OF SATURN. *See* Saturn.

RINGS, FAIRY. This name is given to irregular circles in pastures and lawns on which *Agarics* spring up, and which become much more verdant than the surrounding grass. They are caused by the centrifugal growth of the spawn of the *Agaric*, which radiates from a common centre, and bears the fructification, which is what appears above ground, only at the circumference. The verdure of the grass where these fungi grow seems to be caused either by their manuring the ground when they decay, or by the nitrogen they give off, which is an active stimulant to vegetation. The appellation of *fairy rings* was given to this phenomenon from their being regarded as the places where the fairies held their nocturnal revels.

RING SAIL. A small and light sail set on a mast on the taffrail. Also a studding sail set upon the gaff of a fore and aft sail.

RI'NGWORM. This disease appears in circular patches upon the neck, forehead, or scalp; it begins with clusters of little pustules, which form scabs, leaving a red pimply surface, and destroying the roots of the hair as it proceeds, which it does, if not prevented, over the greater part of the head. It is most common in children of a feeble flabby habit; but as it is communicable by contagion, it generally spreads rapidly in schools and families by the frequent contact of the heads of children, or by the use of the same caps, combs, towels, &c.; so that when it once appears, the diseased boys should be strictly removed from the others. The treatment consists in shaving the head, and using frequent and regular ablutions in the first instance, sponging the part with weak soap and water; when the scabbing begins, other applications must be used, the selection of which must entirely depend upon the degree of irritation and other circumstances. Solutions of nitrate of silver, sulphate of copper, iodide of potassium, or of iron, pitch and tar ointments, petroleum and naphtha, mercurial ointments of different kinds, and various other stimulants, as also sometimes sedatives, are resorted to, to get rid of the morbid state of the part; but so whimsical and obstinate is the disease, that it is impossible to lay down any mode of treatment which can be considered

as approaching to a specific. Except in particular cases no internal medicine has appeared to be of use.

RI'OT, in Law, is said to be a tumultuous disturbance of the peace by three persons or more assembling together of their own authority in order to assist each other against any one who shall oppose them in the execution of a private purpose, and afterwards executing the same in a violent and turbulent manner. A rout is said to be a disturbance of the peace by persons assembled together to do a thing, which, if executed, would make them rioters, and making some motion towards that object; an unlawful assembly, a similar disturbance by persons who neither execute their purpose, nor make any actual motion towards the execution of it.

RIPIE'NO. (It. *full.*) In Music, a term signifying full, and is used in compositions of many parts, to distinguish those which fill up the harmony and play only occasionally, from those that play throughout the piece.

RIPPLE-MARKS. The peculiar undulated marks, which the receding waves leave on the sea beach, and which are occasionally found in some of the older strata of rocks, and are considered as announcing a similar action at a remote period. The wind blowing over a sandy district sometimes occasions a similar appearance.

RITORNE'LLO. (It. *a return.*) In Music, properly a short repetition, such as that of an echo, or of the last words of a song, especially if such repetition be made after a voice by one or more instruments. But by custom this word is now used to denote all symphonies played before the voices begin, and which seem to prelude or introduce what follows.

RI'TUAL. (Lat. ritus, *a rite.*) A book in which the different rites or services of the church are contained.

RI'VER. (Lat. rivus.) In Physical Geography, an inland current of water, formed within a certain portion of the earth's surface by the confluence of brooks, small streams, or mountain torrents, and discharging itself into the ocean, a lake, marsh, or other river. There are few subjects in physical geography which present so wide a field for speculation as rivers, whether we regard them in an historical, political, economical, or scientific point of view. They are associated with the earliest efforts of mankind to emerge from a state of barbarism; but they are no less serviceable to nations which have reached the acmé of civilization. In the earliest ages they were regarded with veneration, and became the objects of a grateful adoration surpassed only by that paid to the sun and the host of heaven. Nor is this surprising; for in countries where the labours of the husbandman and shepherd depended for a successful issue on the falling of periodical rains, or the melting of the collected snows in a far-distant country, such rivers as the Nile, the Ganges, and the Indus were the visible agents of nature in bestowing on the inhabitants of their banks all the blessings of a rich and spontaneous fertility; and hence their waters were held sacred, and they received, and to this day retain, the adoration of the countries through which they flow. But it is by countries which have already made progress in civilization (to which, indeed, they largely contribute) that the advantages of rivers are best appreciated, in their adaptation to the purposes of navigation, and in their application to the useful arts. Like the veins and arteries of the human body which convey life and strength to its remotest extremities, rivers vivify, maintain, and excite the efforts of human industry; whether we regard them near their source as the humble instruments of turning a mill, in their progress as facilitating the transport of agricultural or manufacturing produce from one district to another, or as enriching the countries at their mouths with the varied products of distant lands. This has been so admirably expressed by Pliny, that we cannot refrain from embodying his words in our pages. "The beginnings of a river," he says, "are insignificant, and its infancy is frivolous: it plays among the flowers of a meadow; it waters a garden, or turns a little mill. Gathering strength, in its youth it becomes wild and impetuous. Impatient of the restraints which it still meets with in the hollows among the mountains, it is restless and fretful; quick in its turning, and unsteady in its course. Now it is a roaring cataract, tearing up and overturning whatever opposes its progress, and it shoots headlong down from a rock; then it becomes a sullen and gloomy pool, buried in the bottom of a glen. Recovering breath by repose, it again dashes along, till, tired of uproar and mischief, it quits all that it has swept along, and leaves the opening of the valley strewed with the rejected waste. Now quitting its retirement, it comes abroad into the world, journeying with more prudence and discretion through cultivated fields, yielding to circumstances, and winding round what would trouble it to overwhelm or remove. It passes through the populous cities, and all the busy haunts of man, tendering its services on every side, and becomes the support and ornament of the country. Increased by numerous alliances, and advanced in its course, it becomes grave and stately in its motions, loves peace and quiet, and in majestic silence rolls on its mighty waters till it is laid to rest in the vast abyss."

Most large rivers have their origin in very elevated mountains, or on high table lands, the height and direction of which chiefly determine their size and course. For full information on the various points involved in this subject, we beg to refer the reader to the article "Rivers" in the *Ency. Brit.*; and we shall in this place confine our remarks to some of their most striking peculiarities, — *periodical inundations, occultations,* and *reappearance.*

The *periodical inundations* of rivers depend on great falls of rain in mountainous regions, or on the melting of snows in the neighbourhood of their source. The period depends on the return of these seasons in different places. Within the tropics, the rainy season occurs usually about the time when the sun passes the meridian towards the tropics; and continues until his return to the same place. The rise of the Orinoco commences in May, its inundation begins in June, and the waters return to their channel in September; from which time they decrease until April of the succeeding year. In the Lower Mississippi, whose inundations begin in March, and are at their height in June, are found those enormous rafts of driftwood (formed during the inundations), which sometimes extend for ten or twelve miles in one mass, rise and fall with the stream, yet have a luxurious vegetation on their summits. The great rivers of Asia — the Ganges, the Indus, the Tigris, and Euphrates — have also their periods of inundation, depending on the circumstances determining the setting in of the rains on the mountains in which they originate. In the Ganges the waters begin to increase in April, and at the end of July the country, for an hundred miles along its banks, presents the appearance of a vast lake interspersed with insulated villages and woods. But of all inundations, those of the Nile are the most celebrated; nor is it possible to find any where among terrestrial objects a more striking instance of the stability of the laws of nature, than the periodical rise and fall of this mighty river. We know by the testimony of antiquity that the inundations of the Nile have been the same, with respect to their season and duration, for three thousand years. Indeed, their certainty regulates the public revenue; for when by means of nilometers it is ascertained that the waters promise an unusually prosperous season, the taxes are proportionally increased. Shortly after the commencement of the rains of Abyssinia, in June, the river begins to rise, and attains its greatest height in August. At Cairo the greatest rise is twenty-eight feet; but in the valley of the Nile, with a mean breadth of three or four leagues, it is only four feet. It decreases gradually until the following May; and as soon as the waters are within their usual channel, the soil, moistened and enriched by the sediment deposited from the inundation, is diligently cultivated by the natives. Pliny thus speaks of the inundation:—"Justum Incrementum est cubitorum 16, minores aquæ non omnia rigant: ampliores detinent tardius recedendo. Hæc serendi tempora absumunt: illæ non dant sitiente. Utrumque reputat provinciæ. In duodecim cubitis famem sentiant, in tredecim etiamnum esurit; quatuordecim cubita hilaritatem afferant, quindecim securitatem, sexdecim delicias." (*Hist. Nat.* lib. v. 9.)

The *engulphment and reappearance* of some rivers have attracted attention in every age; nor has any satisfactory explanation been yet assigned for this extraordinary phenomenon. In the Memoir of the Abbé Guettard, the phenomenon in question is accounted for by the spongy nature of the soil through which such rivers flow; thus the Guadiana, one of the largest rivers in Spain, suddenly disappears in the marshes near the village of Castillo de Cerrera, and after pursuing a subterraneous course for twelve or fourteen miles bursts again into day. Limestone districts afford many specimens of this phenomenon; one of the most striking of which is the occultation of the Rhone near the gorge called the *Perte.* There are also some curious instances in Derbyshire and Yorkshire. But no country surpasses Greece in the number of its subterranean streams, the peculiarities of which are often clothed in splendid mythological fictions by her ancient bards. The waters of many valleys in the Peloponnesus have no other outlets than ζεςεθρα, or chasms, which engulph them; such are the outlets of the valleys of Tegea, Mantinea, Asæa, Stymphalus, Peneus, &c. A familiarity with such phenomena, and a poetical temperament, readily led the ancient Greeks to conceive still more distant secret communications; and the imagination which peopled every grove, and animated every stream with presiding deities, could easily reconcile itself to the story of the river god Alpheus, who was said to pursue his favourite nymph Arethusa beneath the bed of the ocean from Greece to the shores of Sicily. (*Traill's Physical Geography.*)

We subjoin, from Dr. Traill's valuable Treatise on Physical Geography, a table showing the length of the course of twenty-two of the principal rivers of the

world, and the area of their respective basins, together with their proportional lengths in English miles; a calculation which has been obtained by multiplying them by 180, being the distance between the remotest sources of the Thames, which is assumed as unity, and its embouchure at the Nore.

Rivers.	Length.	Length in English Miles.	Proportional Magnitude of Basin.	Area of Basin in English Miles.
Europe.				
Thames - -	1	180	1	5,500
Rhine - -	4½	810	12½	70,000
Loire - -	4	720	8¾	48,000
Po - - -	2¼	400	5	27,000
Elbe - -	4½	820	9	50,000
Vistula - -	4¼	760	13½	76,000
Danube - -	9¾	1750	56	310,000
Dnieper - -	7¾	1390	36	200,000
Don - -	7½	1350	37	205,000
Asia.				
Wolga - -	14	2520	94	520,000
Euphrates - -	9¾	1750	42	230,000
Indus - -	11½	2070	72½	400,000
Ganges - -	10	1800	76	420,000
Kang-tse, or Great River of China -	21½	3870	138	760,000
Amour, Chinese Tartary - -	16	2880	164	900,000
Lena, Asiatic Russia	13½	2430	174	960,000
Oby, ditto - -	15	2700	236	1,300,000
Africa.				
Nile - -	18½	2330	90	500,000 uncertain.
America.				
St. Lawrence, including lakes -	22½	4050	109	600,000
Mississippi - -	19	3420	249	1,368,000
Plata - -	13½	2430	225	1,240,000
Amazon, not including Araguay -	22¾	4095	395	2,177,000

For an account of the phenomena of the Australian rivers, which, in apparent contrariety to the laws of nature in other parts of the world, become narrower the further they flow from their source, see the *Geog. Dict.*, art. "Australia."

River. In Hydraulics, a current of water flowing in an open channel. The velocity of a current of water flowing in an open channel depends on the volume of water, the form of the channel, and its inclination; and the determination of the relations subsisting among these three quantities is a problem of great practical importance, the solution of which must be derived partly from experiment, and partly from the general theory of the motion and resistance of fluids.

If water, whether flowing in pipes or open channels, suffered no resistance from the solid matter with which it comes in contact, the velocity would depend solely upon the accelerating force of gravity, and at any point of the channel would be in proportion to the square root of the difference of level between that point and the source. But this velocity, if not constantly impeded, would soon become enormous, and render rivers the immediate instruments of devastation and ruin to the earth. The Rhone, for example, which receives its principal waters at an elevation of 900 feet above the level of the sea, would enter the bay of Marseilles with a velocity of 164 miles in an hour, such being the velocity due to a heavy body falling from a height of 900 feet. Even the Thames, which has a descent of only 100 feet, would acquire a velocity of 54 miles in an hour.

The forces which tend to impede this constantly increasing velocity depend upon the quantity of surface exposed to friction and the velocity of the stream. Let l denote the length of a portion of the stream through which the velocity and the form of the channel remain the same, and c the length of the line of intersection of the channel with a vertical plane perpendicular to the stream (*i. e.* the perimeter or boundary of the transverse section *minus* the superficial breadth); then the surface exposed to friction is represented by $c\,l$. With respect to the velocity, it is found by experiment that the resistance is expressed by a function of the velocity made up of two parts, one depending on the velocity simply, and the other on its square. Hence, denoting the friction or resistance by f, and the mean velocity by v, and assuming m and n, two constant numbers, to be determined by experiment, the resistance will be expressed by this formula: —

$$f = (m\,v + n\,v^2)\,c\,l.$$

Now the force which opposes the velocity is the resistance, and the force which tends to accelerate it is the component of the weight in the direction of the slope; and as the velocity of the portion under consideration is regarded as uniform, these two forces must be equal to each other. Let a denote the area of the transverse section of the stream, then the bulk is $a\,l$, and its weight $g\,a\,l$; the resolved part of which in the direction of the slope is $g\,a\,l \sin. i$, where i is the inclination of the surface to the horizon. We have, therefore, $f = g\,a\,l \sin. i$, or $(m\,v + n\,v^2)\,c\,l = g\,a\,l \sin. i$; whence for any length l for which the area of the section, the slope, and form of the channel remain unchanged, we have $(m\,v + n\,v^2)\,c = g\,a \sin. i$.

If we assume $R = a \div c$ (the area of the section divided by the length of its boundary diminished by the width), then the formula becomes $m\,v + n\,v^2 = g\,R \sin. i$. This quantity R is what is usually called the *radius* of the section, and sometimes the *hydraulic depth*. It is the depth which the river would take if it flowed in a rectangular channel, whose breadth is equal to the bottom and sides of the actual bed.

The constants m and n have been determined experimentally by Prony (*Récherches Physico-Mathématiques sur la Théorie des Eaux Courantes*, Paris, 1804). On reducing his measures to English feet, and rejecting the term $m\,v$, which is small in comparison of $n\,v^2$, the formula becomes

$$v = 109{\cdot}53\,\sqrt{R \sin. i}.$$

Eytelwein (*Handbuch der Mechanik fester Körper und der Hydraulik*, Berlin, 1801) gives $v = 94{\cdot}87\,\sqrt{R \sin. i}$. As a sufficiently near approximation, we may assume $v = 100\,\sqrt{R \sin. i}$; and if we denote the fall in feet each mile by h, we shall have $\sin. i = h \div 5280$, and the formula will become on reduction $v = \frac{11}{8}\sqrt{R\,h}$ nearly. This gives the velocity in feet per second. To find the velocity in miles per hour, we must multiply by 3600, and divide by 5280, which gives $v = \frac{15}{16}\sqrt{R\,h}$; a formula found to be sufficiently conformable to experiments.

From the above formula the mean velocity v is given, when R and h are determined; or, generally, any one of the three quantities, the mean velocity, the hydraulic depth, and the fall, is determined in terms of the other two. It is necessary to observe, that the velocity is not the same in all the parts of the section of the stream. The filaments of water in contact with the bottom and sides of the channel are arrested by the friction, and in their turn retard the filaments next above them in consequence of their adherence or viscidity; so that the filaments which suffer the least retardation are those at the surface and nearest the middle of the stream. On the other hand, the hydrostatic pressure tends to give the greatest velocity to the filaments which are deepest under the surface. By the combination of these two causes, the greatest velocity in an open channel of a symmetrical form is at the middle, and at a small depth under the surface.

The mean velocity, which has been denoted by v, is that which, when multiplied by the area of the transverse section, gives the total quantity of water which passes through the section in a given time. Du Buat found that the greatest velocity is to the mean velocity of the whole section in the ratio nearly of 5 to 4; so that if the greatest velocity is experimentally determined, we may assume the mean velocity to be 4-5ths of the quantity given by the experiment. It was found by Du Buat that if from the square root of the velocity in the middle of the stream, expressed in *inches per second*, unity be subtracted, the square of the remainder gives the velocity at the bottom.

Since the mean velocity of a river is proportional to the square root of the hydraulic depth (the inclination remaining the same), it follows that on contracting the channel the velocity will be increased. When a river receives a permanent addition, the first effect is to increase the velocity, whereby the attrition on the sides and bottom is also increased; and the sides being generally of softer materials, the consequence is that the width, and sometimes, though more rarely, the depth, is increased until the resistance is again equal to the accelerative force, and the velocity becomes uniform.

It is frequently of great importance to determine the whole quantity of water furnished by a river, or, as it is called, the *discharge*. For this purpose the figure of the bed must be accurately determined, which may be done by soundings. This also gives the area of the section, and consequently the hydraulic depth. The velocity at the surface may be determined by means of a float; or at a small depth under the surface by the instrument called *Pitot's tube* (see the term), or by measuring the force of the current by means of a dynamometer.

See, in addition to the works above quoted, Bossut, *Traité d'Hydrodynamique*; Navier, *Leçons sur l'Application de la Mécanique*; Belidor, *Architecture Hydraulique*.

RIVO'SE. (Lat. rivus, *a brook.*) In Zoology, when the surface of an animal or part is marked with furrows which do not run in a parallel direction, and are rather sinuate.

RIXDOLLAR. (A corruption of Germ. reichsthaler, or *dollar of the empire.*) A silver coin of different values in different countries. *See* Money.

ROACH. The curve, or arch, which is generally cut

in the foot of some square sails, from one clue to the other, to keep the foot clear of stays and ropes.

ROAD, or ROADSTEAD. A place of anchorage. A vessel when at anchor is termed a roadster, in contradistinction to another under sail.

ROADS, are pathways formed through a country, by which passengers and commodities may travel, or be transported, with more or less facility and expedition, from one place to another. Roads are of various kinds, according to the state of civilization and wealth of the country through which they are constructed, and according to the nature and extent of the traffic to be carried on upon them, — from the rude paths of the aboriginal people, carried in direct lines over the natural surface of the country, passable only by foot passengers or pack-horses, to the comparatively perfect modern road, carried on an artificial causeway, and reduced to a nearly level surface at enormous expense by means of vast excavations, extensive embankments, bridges, viaducts, tunnels, and other expedients supplied by the skill and ingenuity of the civil engineer.

Advantages of Roads. — There is no expedient which more powerfully conduces to the advancement of a people in civilization, or to the extension of their prosperity and national wealth, than the construction of good roads, connecting the various centres of commerce and of industry about which they may have collected themselves. The invention of printing, the expedient of money, the adoption of a uniform system of weights and measures, would severally be ineffectual, or productive of advantages of a very limited extent, if the intercommunication of those whose feelings and ideas are expressed and conveyed in print, and among whom money is made to circulate, and whose commerce is stimulated and facilitated by the uniform module of quantity supplied by weights and measures, were not facilitated and expedited by the means of conveyance supplied by roads. Without roads, the interchange of advantages, moral, intellectual, and physical, which now takes place in all highly civilized countries between the rural and the urbane population, could not be maintained; without them, indeed, large towns or cities could not continue to exist. The supply of the population collected in such places with the various products of agriculture, necessary to their physical existence, could not be sustained. Nor, on the other hand, would the rural population affording that supply be benefited by a return in exchange of the refinements of the town, and the various articles of luxury and necessity obtained by commerce from every part of the globe.

But roads are not less necessary for the advancement of agriculture itself, than for the due maintenance of the necessary relations between the towns and the country. Without the aid of roads, it would be impossible to apply those arts to the soil by which increased powers of production are given to it. Without roads, the various kinds of manure, by which the scientific farmer knows how to raise augmented crops, could not be transported to his fields from the place, often distant and difficult of access, where such manures are found. Roads may then, in fact, be considered as a system of veins and arteries, by which all those principles necessary for the maintenance of the prosperity of a country are kept in circulation.

History of Roads. — The importance of roads to the welfare of nations was not unknown to the ancients. The senate of Athens, the government of the Lacedemonians, the Thebans, and other states of Greece, bestowed much care upon them; but, as might naturally be expected, the first great advances in the art of intercommunication by roads were due to a people essentially commercial. The invention of paved roads is traced to the Carthaginians. Rome, ever awake to the advantages to be gained from conquered people, followed in the steps of the Carthaginians, and vastly extended and improved their processes in the construction of roads.

The Via Appia, the Via Aurelia, and the Via Flaminia were the first great monuments of the Roman people in this department of art. Under Julius Cæsar, the capital of the empire was made to communicate with all the chief towns by paved roads; and during the last African war, a road of this kind was constructed from Spain through Gaul to the Alps. After this, these great lines of communication were extended through Savoy, Dauphiné, and Provence; through Germany, every part of Spain; through Gaul, and even to Constantinople; through Asia, Hungary, Macedonia, and to the mouths of the Danube. Neither did the interposition of seas obstruct the labour or daunt the enterprise of this great people. The lines of communication thus constructed to the shores of the continent of Europe were continued at corresponding points of the neighbouring islands and continents. Sicily, Corsica, Sardinia, England, Africa, and Asia were accordingly intersected and penetrated by roads, forming the continuation of the great European lines. These gigantic works were not mere paths prepared for the action of the feet of horses and the wheels of carriages, formed upon the natural surface of the ground, but were constructed on principles in some respects as efficient as those which modern engineering has supplied; forests were opened, mountains excavated, hill slowered, valleys filled up, chasms and rivers bestridden by bridges, and marshes drained, to an extent which would bear no mean comparison to the result of the great engineering enterprise of recent times.

English Roads. — The first roads of artificial construction in England were those formed by the Romans while it was a Roman province. A grand trunk road was carried through the country north and south, and another nearly at right angles to it east and west. These main lines were supplied with branches, extending in every direction which the conquerors found it expedient to render accessible to their arms. The Roman road called Watling Street commenced from Richborough in Kent, the ancient Ruterpiac, and being carried through London in a north-westerly direction, was continued to Chester. The road called Ermine Street commenced from London, and passing through Lincoln was carried thence through Carlisle into Scotland. The Foss Way passed from Bath, in a direction north-east, and joined the Ermine Street. The road called Ikenald extended from Norwich, in a southward direction, to Dorsetshire.

The example thus afforded by their conquerors was not followed by the Britons, who, unconscious of the many advantages attending facilities of intercommunication, relapsed into the barbarous neglect of roads; and while the Roman ways were allowed to fall into decay, new roads were not constructed. For many centuries, such intercourse as was maintained between the various parts of this country took place almost exclusively by rude paths, capable of being passed on foot, or at best by horses, carried over the natural surface of the ground in straight directions from place to place. Hills were surmounted, valleys crossed, and rivers forded, in the same manner as the savages of the most remote wilds of America now communicate with each other, or with the settlers. It was not till the reign of Charles II. that any attempt was made by the legislature to improve the roads of the country. In the 16th year of the reign of that monarch, the first turnpike-road was established by law, whereon toll was taken. It passed through Hertfordshire, Cambridgeshire, and Huntingdonshire. It was not, however, till about a century from the present time, that any great or effectual attempts were made to establish a system of good roads through the country. Till nearly the middle of the last century, most of the goods were conveyed from place to place in Scotland on pack-horses. Oatmeal, coals, turf, and even straw and hay, were conveyed in this way; but in carrying goods between distant places it was necessary to employ a cart, as all that a horse could carry on his back was not sufficient to defray the cost of a long journey. The time that the carriers usually required to perform their journeys seems now almost incredible: the common carrier between Selkirk and Edinburgh, a distance of thirty-eight miles, required a fortnight for his journey, going and returning. The road, for a considerable extent, lay along the bottom of the district called Galt Water; the bed of the stream, when not flooded, being the tract chosen, as the most level and easiest to travel in.

Nor were the means of travelling between large towns much better. In 1678, a contract was made to establish a coach between Edinburgh and Glasgow, a distance of forty-four miles. This coach was to be drawn by six horses, and the journey between the places, to and from, was engaged to be completed in six days; even so recently as the year 1750, the stage coach from Edinburgh to Glasgow took a day and a half to make the journey.

In the year 1763, there was but one stage coach between Edinburgh and London, which started once a month from each place, and took a fortnight to perform the journey. At the present time, after the lapse of not so much as eighty years, there are seven coaches daily start from each of these cities for the other; besides several steam ships of enormous magnitude, which sail weekly from each place, supplying all the accommodation and luxury of floating hotels, and completing the journey, in common with the coaches, in less than forty-eight hours. If each of the coaches be estimated as conveying ten passengers daily, the coaches alone would thus convey daily between these cities about 140 passengers, or above 4000 monthly. If an equal number be estimated as conveyed by the steam ships, we should have the present intercourse in passengers between London and Edinburgh amounting to about 8000 monthly; whereas, in 1763, the number conveyed by stage coaches between these places monthly could not have exceeded twenty-five, and by all the means of conveyance then existing probably did not exceed fifty.

It happens that the line of road now occupied by the Liverpool and Manchester Railway and its branches, and travelled daily by thousands of passengers, at a speed of twenty-five miles an hour, including stoppages, was, in the year 1770, travelled over by Mr. Arthur Young, who has left us in his Tour the following account of the state of the roads at that time: — "I know not in the whole

range of language terms sufficiently expressive to describe this infernal road. Let me most seriously caution all travellers, who may accidentally propose to travel this terrible country, to avoid it as they would the devil; for a thousand to one they break their necks, or their limbs, by overthrows or breakings-down. They will here meet with ruts, which I actually measured four feet deep, and floating with mud only from a wet summer. What, therefore, must it be after a winter? The only mending it receives is tumbling in some loose stones, which serve no other purpose than jolting a carriage in the most intolerable manner. These are not merely opinions, but facts; for I actually passed three carts broken down in these eighteen miles of execrable memory." With the exception of a few rare instances of important roads, constructed under special acts of parliament, the roads of England have not been constructed on any scientific principle, and are, in most cases, nearly coincident with the foot and horse paths adopted by the early inhabitants of the country. These rude paths having been formed at an early period, the only roads of communication between the chief towns were gradually improved, so as to be capable of being travelled over by wheel carriages. The natural surface of the ground was in time covered with an artificial coating of gravel or stones; hills too steep to be surmounted by carriages were either levelled, and the material obtained from their excavation thrown into the valleys, or the roads were carried round them; at a later period fences were added; and thus, by slow degrees, the old horse path grew into the modern road. How far removed from a truly good and scientific line of communication such a road must be, will be apparent to any one who considers what the principles ought to be on which a road should be laid down and constructed.

The Art of Road-making.—When it is proposed to construct a line of road extending between two places, the engineer upon whom such a duty devolves first makes himself well acquainted with the surface of the country lying between the two places, so as to obtain an acquaintance with the face of the country, somewhat approaching to that which would be supplied by a superficial model of it, which would exhibit all its inequalities and undulations of surface. He is then to select what he considers, all circumstances being taken into account, the best general route for the proposed road. But, previously to laying it out with accuracy, it is necessary to make an instrumental survey of the country along the route thus selected; taking the levels from point to point throughout the whole distance, and making borings in all places where excavations are required, to determine the strata through which such cuttings are to be carried, and the requisite inclinations of the slopes or slanting sides, as well of the cuttings as of the embankments to be formed by the material thus obtained. It is also requisite, in the selection of the route for the proposed road, to have regard to the supply of materials, not only for first constructing it, but for maintaining it in repair; thus, the position of gravel pits and quarries in the neighbourhood of the proposed line, and the modes of access to them, should be well ascertained.

The results of such an investigation should be reduced to a plan and section; the plan of the road being on a scale not less than 66 yards to an inch, and the section not less than 30 feet to an inch.

The loss of tractive power, and danger to travellers produced by steep acclivities, render it especially necessary that a proper limitation should be imposed upon the inclinations or acclivities on every line of road on which much traffic is carried on. As, however, this reduction of hills in a country where much inequality of surface exists is attended with a considerable outlay of capital, the engineer will have to balance the cost of constructing a road having the best possible inclinations against the advantages to be obtained in the permanent working of the road; and if the expected traffic be not such as to yield advantages proportionate to the capital absorbed, greater rates of inclination must be allowed to the hills, with a view to diminish the extent of the works, and to render the expense of constructing the road proportionate to the traffic expected upon it.

A dead level, even where it can be obtained, is not the best course for a road; a certain inclination of the surface facilitates the drainage, and keeps the road in a dry state. There is a certain inclination, depending on the degree of perfection given to the surface of the road, and on the structure of the carriages worked upon it, which cannot be exceeded without a direct loss of tractive power; this inclination or acclivity is that in descending which at a uniform speed the traces slacken, or which causes the carriages to press on the horses: the limiting inclination within which this effect does not take place is called the *angle of repose.*

On all acclivities less steep than the angle of repose, a certain amount of tractive force is necessary in the descent as well as in the ascent; and the mean of the two drawing forces, ascending and descending, is equal to the force along a level road. Thus, on such acclivities as much power is gained in the descent as is lost in the ascent; but on acclivities which are more steep than the angle of repose, the load presses on the horses during their descent, so as to impede their action, and their power is expended in checking the descent of the load; or, if this effect be prevented by the use of any form of drag or break, then the power expended on such drag or break corresponds to an equal quantity of mechanical power expended in the ascent, for which no equivalent is obtained in the descent.

On well-constructed roads, with carriages such as now are generally used in England, the angle of repose may be taken at about one in thirty-six; and this is consequently an acclivity which ought not to be exceeded on roads over which much traffic is carried.

The expedients by which the requisite inclinations are obtained on common roads are the same as those which are resorted to in the construction of railways. *See* RAILROADS.

The exact course of the road and the degree of its acclivities being determined, the next thing to be considered is the formation of its surface. The qualities which ought to be imparted to it are twofold,—first, it should be smooth; secondly, it should be hard; and the goodness of the road will be exactly in the proportion of the degree in which these qualities can be imparted to it, and permanently maintained upon it. An error prevailed among road engineers until a very recent period. It was considered that smoothness of surface alone was sufficient for the perfection of a road; and that, provided it could be made sufficiently durable, it was unimportant how soft or yielding the coating of the road might be. This error, into which, among others, Macadam himself fell, was based upon a neglect of one of the most important circumstances to be considered in the construction of a road. The main object to be attained by all roads is the diminution of the resistance which a carriage opposes to the tractive power. Other things being the same, it was sufficiently apparent that this resistance would be diminished by increasing the smoothness of the road surface. But roughness or unevenness of surface is not the only cause of resistance to the tractive power: if two roads have their surfaces equally smooth and even, but one is soft and elastic, so as to yield under the pressure of the wheel, recovering its form as the wheel advances, and the other is hard and unyielding, the resistance to the tractive power will be greater on the soft and yielding road than on the hard and unyielding road; and this augmentation of resistance will be in proportion to the softness of the surface. That this would be the case, admits of immediate demonstration on mechanical and mathematical principles; but, without resorting to these, it must be sufficiently apparent from the results of the most common experience. A surface of velvet may be as smooth and even as a surface of ice; but if an ivory ball be rolled on the latter, it will continue its motion much longer than on the former. In fact, the wheels of a carriage in passing along a soft road sink into its surface, as the ball would sink into the pile of the velvet; and although, in virtue of its elasticity, the surface of the road, like that of the velvet, may recover its smoothness after the pressure has been removed from it, still a resistance will be offered to the drawing or impelling power, which would not be produced by a hard and unyielding surface equally smooth.

Macadamization.—This process, which has received its name from Macadam, to whose labours the improvement of the roads of England within the last half century owes so much, consists in forming the road crust of stones, broken with a hammer into angular pieces of a small and uniform size. This method, however, is one which was long practised in various parts of Europe. When the stones of which the road crust is to be formed are broken to the proper magnitude and form, they are spread over the surface of the road in a layer of 3 or 4 inches thick. After this has been consolidated by carriages working upon it or by rollers, another layer of broken stones of equal depth is laid upon it; it is consolidated in like manner; and thus one layer is laid over another until an artificial crust is formed of broken stones of sufficient thickness to give the requisite strength to the road.

A coating or road crust thus formed might be constructed on any substratum whatsoever, and a smooth and apparently good road would be obtained. It was the practice of Mr. Macadam to disregard the nature of the substratum; and he maintained that if it was not such a bog as would not allow a man to walk over it, he would even prefer it to a hard bottom.

Telford's System.—The improvement in road-making which consisted in a due attention to the substratum or foundation of the road, so as to give increased facility to the tractive power by rendering its surface hard and unyielding, is due to the late Mr. Telford. The following is a description of the method of constructing such a road practised by that eminent engineer.

Upon the level bed prepared for the road materials a bottom course or layer of stones is to be set by hand, in form of a close firm pavement. The stones set in the

middle of the road should be 7 inches in depth; at 9 feet from the centre the depth should be 5 inches; at 12 feet, 4 inches; and at 15 feet, 3 inches; the entire width of the road being 30 feet. These stones are to be set on their broadest edges lengthwise across the road, and the breadth of the upper edge should not exceed 4 inches. All the irregularities of the upper part of this pavement are to be broken off by hammers, and all the interstices to be filled with stone chips firmly wedged or packed by hand with a light hammer; so that, when the pavement is finished, its cross section shall have a convexity of surface of about 4 inches in the centre above the extreme edges: 18 feet in the centre of this pavement are to be coated with a layer of hard broken stones, 6 inches deep; of these 6 inches, 4 must be first put on and worked down by carriages and horses in the ordinary traffic of the road, care being taken constantly to rake in the ruts until the surface has become firm and the crust consolidated. After this, the remaining 2 inches of stone may be put on; the whole of this stone, forming 6 inches of crust, is to consist of pieces broken as nearly as is practicable into a cubical form, and of such a magnitude that they can pass through a ring of 2½ inches internal diameter. The spaces on each side of the middle 18 feet are to be coated with broken stone or well-cleansed strong gravel up to the level of the footpath or other boundary of the road, so as to make the whole convexity of the road 6 inches in the middle above the level of the edges; and the whole of the materials thus formed and consolidated should be covered with a coating 1½ inch deep of good gravel, free from clay or earth.

Such was the method practised by Mr. Telford in the construction of great main roads, such as that between Holyhead and Shrewsbury. In the streets of towns, and other places where roads have to bear a still heavier traffic, such a road as that above described is found to be subject to a superficial wear, so rapid as to produce an intolerable quantity of dust in summer and of mud in winter. In such places recourse has been generally had to pavement. The first object to be secured for a durable pavement, as well as in other roads, is to secure a good foundation. The best method is to lay a foundation of gravel or broken stone, the bed of which should be formed with a convexity sloping to each side by a fall of about 1 in 50. After the first layer of broken stone is put on, the street should be open for carriages to pass over it until it is consolidated, all ruts being carefully raked in. The same process should be repeated with each successive layer, until a sufficiently solid foundation is obtained for the pavement. On this foundation a pavement formed of blocks of stone is laid, the blocks being 10 inches in depth, from 10 to 15 inches in length, and from 6 to 8 inches in width. Such is the structure which is requisite for the streets which are the main thoroughfares of a great city; a pavement with less strength of foundation, and formed of smaller blocks of stone, being used for the streets of less intercourse.

The many inconveniences produced in the great thoroughfares of London, such as Oxford Street, Holborn, Fleet Street, the Strand, &c., by reason of the rapid wear of every kind of pavement hitherto adopted, a suspension of the intercourse during the frequent repairs, the dust in summer and the mud in winter produced by a surface of broken stones, and the intolerable noise produced by every species of stone pavement, have lately excited much inquiry as to the possibility of constructing some road having sufficient strength for a traffic so enormous, sufficient durability to prevent the inconvenience of the frequent suspension of intercourse by the necessity of repairs, and presenting a surface which, while it would be free from the noise of a stone pavement, would not be attended with the inconvenience of dust and mud produced by a surface of broken stone. This problem appears to be in a great degree solved by the adoption of a pavement of wood. A short piece of Oxford Street was thus paved in the beginning of 1839; and after a successful trial of several months, the same pavement was extended nearly throughout the whole extent of that street; and at the present time (1842) this method of pavement is in process of construction in several other thoroughfares of London. The idea of a wooden pavement is not new. In the northern parts of Germany and in Russia such pavements have been long in use; some of the main streets of Petersburgh and Vienna have long been paved in this manner. A few years ago a series of experiments were made at New York, to determine the best description of paving for a street. One of the methods adopted was a tesselated pavement, formed of hexagonal blocks of pine wood, measuring 6 inches on each side of their transverse section, and 12 inches in depth. From the manner in which the timber is cut its fibres are vertical, and therefore the tendency to wear from vertical pressure is small. The blocks are coated with pitch or tar, forming a smooth upper surface.

Various methods have been proposed for laying the wood pavements of London; but as these methods are severally as yet only in process of trial, nothing is practically known of their respective merits. There appears, however, to be sufficient to justify a well-grounded expectation that wood pavements of some form or other will soon supersede all others for the great thoroughfares of towns.

Concerning the formation of roads of various kinds, their drainage, fencing, their management, repairs, &c., much might be said; but the limits which must be imposed on this article compel us to refer the reader for these details to Sir Henry Parnell's *Treatise on Roads*. See also the *Encyclopédie*, article "Chemin;" Bergier, *Histoire des Grands Chemins de l'Empire Romain; Annales des Ponts et Chaussées;* Anderson's *Commerce;* M'Culloch's *Treatise on Commerce*, *Library of Useful Knowledge;* Mr. Telford's *Reports*

ROA'STING, in Chemical Metallurgy, means the protracted application of heat to metallic ores, below their fusing points. It is generally resorted to to expel volatile matters, especially sulphur, arsenic, carbonic acid, water, &c.

ROB. A term of Arabic origin, applied by old pharmaceutical writers to thin extracts or inspissated juices.

RO'BBERY (from the Germ. rauben, *to rob*), in Law, is defined a felonious taking of money or goods of any value from the person of another, or in his presence, against his will, by violence or putting him in fear; and this, whether the fear be of injury to the person's property or character. But it is necessary that the fear be of immediate injury, not of some future injurious results; and then the money must, generally speaking, be taken immediately upon the threat made, and not afterwards given from fear of consequences. But the *extortion* of money by threat to accuse of an infamous crime was made robbery by 7 & 8 G. 4. c. 29. The law on the subject is now collected in the recent statute 1 Vict. c. 29.; and robbery is capital only when the robber "at the time, or immediately before or after," stabs, cuts, or wounds any person.

ROBES, MASTER OF THE. An officer in the royal household, whose duty, as the designation implies, consists in ordering the sovereign's robes. Under a queen, this office, which has always been one of great dignity, is performed by a lady, who enjoys the highest rank of the ladies in the service of the queen.

RO'C, or RU'KH. The well-known monstrous bird of Arabian mythology, of the same fabulous species with the simurg of the Persians. In the notes to vol. iii. of Mr. Lane's edition of the *Arabian Nights' Entertainments* are some curious extracts from the writers of old voyages of that nation; showing that the tale was either founded on, or supported by, the wonderful accounts of travellers. Even Sinbad's well-known adventure, when his crew broke the roc's egg, and were attacked in consequence by the enraged pair of birds, is borrowed from the serious narration of Ibn-El-Wardee. The roc is also described by Marco Paulo. (Marsden's transl., p. 707.) The size of this famous monster is, of course, described with all the luxuriance of oriental imagination. Ibn-El-Wardee makes one of its wings 10,000 fathoms long. Mr. Lane appears to think that this extravagant fiction was suggested by the condor; but the size and power of that bird are much exaggerated, even in the common accounts. The bearded vulture of Egypt seems a better archetype of the rukh. In a drawing from an illuminated Persian MS., which Mr. Lane has copied, the roc, or rather simurg, which is represented as performing the slight operation of carrying off three elephants in its beak and claws, is something like a cock, with eagle's wings and an extravagant tail. The simurg is a creature of importance in Persian mythology: it is the phœnix of oriental fable, one only living at a time, and attains the age of 1700 years. (See the notes to *Southey's Thalaba.*)

ROCELLIC ACID. An acid obtained from the *Rocella tinctoria*.

ROCHE'LLE SALT. The tartrate of soda and potassa. It is a double salt, composed of 2 equivalents of tartaric acid ($66 \times 2) = 132$, 1 equivalent of potassa $= 48$, and 1 of soda $= 32$. Its crystals, which are large and well-defined prisms, often presenting eight, ten, or twelve sides, include 8 equivalents ($9 \times 8) = 72$ of water.

ROCK. *See* Geology.

ROCK CORK. A variety of asbestos, which see.

ROCK CRYSTAL. A common mineralogical term applied to crystallized silica: it is also called *quartz*.

RO'CKET. In the Military Art, a very destructive species of fire-work, the best kind of which was invented by the late Sir William Congreve, and called after him the *Congreve rocket*. The body of the machine is cylindrical, and its head conical. It is filled with very inflammable materials; on the combustion of which, as in the common sky-rocket, the body is impelled forward with a continual acceleration.

ROCKING or LOGGING STONES. *See* Geology.

ROCK SALT. Common salt found in masses or beds in the new red sandstone, as in Cheshire and elsewhere. *See* Geology.

ROCK SHELLS. The common name of certain Uni-

valves, characterized by the long straight canal which terminates the mouths of their shells. *See* MUREX.

ROCKWORK. In Architecture, masonry wrought in imitation of rough stone, in various arrangements, and chiefly used in basements of buildings.

ROCKWORK, in Gardening, is applied to a quantity of stones, fragments of rock, or even vitrified bricks, piled together in such a manner as to form a nidus for the growth and display of alpine plants. When the pieces of rock are of such forms as can be connected together so as to present the appearance of stratification, that mode of arranging them may be adopted; and the soil and plants may be placed in vertical, oblique, or horizontal fissures, or on ledges, according to the lines of stratification. When, however, as is most frequently the case, land or water-worn stones are used, they may be distributed over a mound of earth, not uniformly, but in groups, with smooth surfaces of soil between, in the manner that may be observed in nature, where stones of different sizes are seen rising out of the surface of a green hill or hillock. When agglutinated masses of vitrified bricks are used, either alone or mixed with land stones of different sizes, they may be distributed over a mound, or along a bank of soil, in such a manner as to produce a varied surface, without attempting to imitate nature, and with interstices between them for inserting the plants. Imitations of conical hills, caverns, precipices, and even the Alps, on a small scale, have been made in rockwork; but these, and all other imitations of nature, require to be designed and directed by the eye and mind of an artist. In general the piles of stone called rockwork, in botanic and flower gardens, might with more propriety be called heaps of stones.

ROD. A measure of length, otherwise called a *pole*. It is 5½ yards, or 16½ feet; and four of these make the *Gunter's chain*.

RO'DENTS, *Rodentia*. (Lat. rodo, *I gnaw*.) The name given by Cuvier to the *Glires* of Linnæus, an order of Unguiculate Mammals, comprehending those which have two long chisel-shaped incisors in each jaw, and no canines, but a vacant interspace between the incisors and the molars; the lower jaw is articulated by a longitudinal condyle, in such a way as to allow of no horizontal motion, except from back to front, and *vice versâ*, as is requisite for the action of gnawing. The molars also have flat crowns, whose enamelled eminences are always transverse, so as to be in opposition to the horizontal motion of the jaw, and to increase the power of trituration. The genera in which these eminences are simple lines, and the crown is very flat, are more exclusively frugivorous; those in which the eminences of the teeth are divided into blunt tubercles are omnivorous; while the small number of such as have no points more readily attack other animals, and approximate somewhat to the Carnaria. The form of the body in the Rodentia is generally such that the hinder parts of it exceed those of the front, so that they rather leap than walk. In some of them this disproportion is even as excessive as it is in the kangaroos. In the whole of this class the brain is almost smooth, and without furrows; the orbits are not separated from the temporal fossæ, which have but little depth; and the eyes are altogether lateral. The inferiority of these animals is visible in most of the details of their organization. Those genera, however, which possess stronger clavicles have a certain degree of dexterity, and use their fore feet to convey their food to the mouth.

RODOMONTA'DE. A term that has passed into most European languages; from Rodomont, a boisterous character in the *Orlando Furioso*, — signifying a boastful mode of talking.

ROE. The ova of osseous fishes which are developed simultaneously and in great numbers are so called.

ROESTONE. A granular limestone, or oolite; which see. See also GEOLOGY.

ROGA'TIONS. (Lat. rogo, *I ask*.) In the Ritual, public supplications or litanies were anciently so termed, until the latter designation began to supersede every other. (Palmer, *Orig. Liturgicæ*, vol. i. p. 270.) In the Calendar, the three Rogation days are the Monday, Tuesday, and Wednesday next before Ascension-day.

ROGUE'S YARN. A yarn of a different twist and colour from the rest, and inserted in the royal cordage, to identify it in case of its being stolen.

RO'LLERS. The name given by seamen to unusually heavy waves, which set in upon a coast or island without wind. They are frequent at Ascension.

RO'LLING, in Mechanics, is when all the parts of the surface of one body come into successive contact with those of another, and under such conditions as that at every instant the portion of the two surfaces which *have been* in contact are exactly equal. When this condition is not fulfilled, the one surface is said to slide upon the other. The friction of bodies in rolling is much less than in that of sliding; and hence the advantage of wheels to all kinds of carriages. *See* FRICTION.

ROLLING. In Naval language, the lateral oscillation of a vessel. This motion, which is often very great when the vessel is running before the sea, endangers the masts, strains the sides, and loosens the decks at the waterways; it is also liable to cause the guns to break adrift. When the centre of gravity is too low, the oscillations begin and end violently. The changes in the stowage necessary to modify the nature or extent of the roll are made by seamen from experimental knowledge.

RO'LLING PE'NDULUM. A cylinder caused to oscillate in small spaces on a horizontal plane. Its mathematical expressions are interesting, but it has been applied to no important practical purpose.

RO'LLING TA'CKLE. A tackle or pulley hooked to the weather quarter of a yard, and to a lashing or strap round the mast near the slings or parral of the yard; the object of it is to keep the yard constantly over to leeward thereby depriving it of play and friction when the ship rolls to windward.

ROLLS, MASTER OF THE. A high officer of the Court of Chancery, second only to the lord chancellor. He is appointed by the crown by letters patent, and holds his office for life. The master of the rolls administers justice in a separate court called the Rolls. He has the power of hearing and determining originally the same matters as the lord chancellor, excepting cases of lunacy and bankruptcy; but all orders and decrees pronounced by the master of the rolls must be signed by the lord chancellor before they are enrolled. The master of the rolls is also the chief of the twelve masters in Chancery, and chief clerk in the Petty Bag Office: he is the keeper, also, of all the records of the Court of Chancery after the decrees and orders have been enrolled; and on that account he was anciently styled *guardien des rolles*. The master of the rolls ranks immediately after the chief justice of the King's Bench: his salary, by the stat. 6 Geo. 4. c. 84., is 7000*l*. a year.

Before the passing of the act 3 & 4 W. 4. c. 94. the master of the rolls did not hear motions, pleas, or demurrers; and whatever was presented for his decision, other than the hearing of causes, was brought before him by petition. By the above-mentioned act, however, this was altered; and motions, pleas, and demurrers are now heard by him in the same manner as by the other equity judges. By the act 1 & 2 Vict. chap. 94., entitled "An Act for the better Custody of the Public Records," the master of the rolls for the time being is entrusted with the custody both of the public records and those of the common law courts and Court of Exchequer.

ROMAN ALUM. An alum extracted from the volcanic rocks of the Solfaterra near Naples: it crystallizes in opaque cubes, and appears to contain more alumina than the common octoedral alum.

RO'MAN ARCHITECTURE. *See* ARCHITECTURE.

RO'MAN CA'THOLICS, ROMANISTS, OR PAPISTS. The names by which Protestants designate the members of the large and ancient church, which regards the bishop or pope of Rome as its infallible spiritual head, and assumes to itself the title of the Catholic, or universal. A rapid review of the external fortunes of this system, as connected with the holy see, will be found in the article PAPACY; the principal doctrines, also, by which it is distinguished are detailed under the several heads. (*See* TRANSUBSTANTIATION, MASS, PENANCE, PURGATORY, &c.) It will be sufficient in this place to point out the general argument upon which the Roman system has been erected.

The Roman doctors hold that the Scripture is not sufficient for its own interpretation. The books which compose the canon of the New Testament are, they conceive, desultory and incomplete; being many of them written for special occasions, at a period considerably later than the foundation of the religion in various districts, in some of which whole generations of believers may have passed away without having seen or heard of their precious contents. It is not to be supposed, however, that doctrines so important as those shadowed forth in the Epistles of St. Paul, or the Gospel of St. John, could have been left untaught to the churches which flourished before their publication or beyond their reach. It must be admitted, therefore, they argue, that the first preachers of Christianity must have been commissioned and instructed to deliver these same doctrines orally; and it is affirmed that several important doctrines are imperfectly developed in Scripture, and would not be understood, except for some such illustration by the way, the result of which is conveyed in the creeds of the first centuries. It is also affirmed that the practice of the primitive church, the infallibility of which is assumed, authenticates various articles of Roman belief, of which only very slight hints are to be found in Scripture, and such, perhaps, as would not have been discovered but for this very evidence from the usage. This line of argument is admitted also by many Protestants, the facts alleged being disputed, and opposite results obtained. It must be allowed, however, that the Catholics do not advance any article of belief without pointing out some supposed ground for it in Scripture, although the only shadow of

proof of this kind is in some cases to be found nowhere but in the writings which Protestants esteem apocryphal. But while Protestants may refer to the practice of the primitive church, and the traditions which must have circulated in those ages, as a genuine historical evidence of the scriptural interpretation of the earliest and purest times, they find too much contradiction in the individual witnesses to consider any one system *deduced therefrom* as infallibly right. The Romanists, on the contrary, attaching more importance to this kind of evidence, and labouring under the same difficulty in discriminating between genuine and corrupt traditions, take refuge in the idea of a spiritual head of the church, an authorized interpreter of tradition, an infallible expounder of the faith, and him they seat in the chair of St. Peter at Rome; maintaining that the dogmas which have been advanced from this source have always been those of the Catholic Church, and always authentic. In later times, however, a question has been much agitated respecting the relative authority of popes and councils; the superiority of each has been maintained by different classes of theologians, and it is certain that in some cases the decisions of popes have been ultimately reversed by councils. It is clear that there cannot be anywhere an authority competent to settle the question; but it is believed that the opinion now generally acquiesced in is, that the two are co-ordinate powers, and that infallibility resides in the decrees of a *pope in council*.

ROMA'NCE. In Literature, a work of fiction in prose or verse, containing the relation of a series of adventures, either marvellous or probable. A tale confined to the latter class of events has, indeed, been considered to be more strictly designated by the term *novel*. (*See* Novel.) But as our nomenclature for works of fiction is not very precise or accurate, the name romance is very frequently used to comprehend both.

The term romance is derived from the class of languages in which such fictitious narratives, in modern times, were first widely known and circulated. These were the tongues derived from the Latin, Italian, Spanish, French, which were all Roman dialects, in contradistinction to the European languages of Teutonic origin. But the "langue Romane" more properly signifies the dialect of southern France, Catalonia, &c., of which the Provençal was a variety.

The famous *Milesian Tales* of antiquity are thought to have been, in classical times, the class of writings nearest approaching to our modern romances. All the original Greek compositions of this kind have perished. But we have, in the *Golden Ass* of Apuleius, a Latin imitation of these, written in the later times of the Roman empire. It contains a series of wonderful adventures, sorceries, transformations, love, religion, &c.; and although it has been asserted that the romance, in its proper sense, was unknown to the ancients, it would be difficult to say in what respect, except the total absence of chivalrous sentiment, which is of modern growth, this curious fragment differs from those later inventions which we have agreed to call by that name.

The same may be said, and with even greater strictness, of the Greek pastoral romances; a class of works appertaining to a later period, of which the famous *Daphnis and Chloe* of Longus is the first known specimen. They contain narratives of amours, adventures, &c., usually intermixed with some supernatural interference; and they have the great characteristic of a modern novel, — a pair of lovers, by way of hero and heroine, whose attachment is generally brought to a happy termination.

The earliest modern romances were collections of chivalrous adventures, chiefly founded on the lives and achievements of the warlike adherents of two sovereigns, one of whom, perhaps, had only a fabulous existence, while the annals of the other have given rise to a wonderful series of fables,—Arthur and Charlemagne. These romances were metrical compositions in that branch of the modern French language termed the *langue d'oil*, which prevailed throughout the north of France, and especially in Normandy. Besides these, a great variety of smaller tales, some chivalrous, some marvellous, some simply ludicrous, termed *fabliaux*, exist in the same language. The date of these compositions extends from the 12th to the 15th centuries.

From the hands of these rhymers the tales of chivalry passed first into those of prose compilers, who reduced them into a form more resembling that of our modern romances. The French prose romances of chivalry, still confined to the same classes of subjects, belong to the 14th and 15th centuries. These, again, gave birth in two different countries to two widely differing series of works of imagination. In Italy, the poets termed Romanzieri, taking the adventures of the knights of Charlemagne as their subject, transferred the rude conceptions of their predecessors into one of the most finished and enchanting forms of poetry to which modern fancy has given birth. Boiardo, in the latter half of the 15th century, was the first of these poets; and the names of Pulci, Ariosto, and Tasso, three of the greatest in Italian literature, grace their long catalogue. In Spain and Portugal a new class of chivalrous romances was called into existence. Lobeira, a Portuguese, in the 14th century, composed the first four books of *Amadis de Gaul*. This famous word resembles in character the French romances of chivalry; but narrates the exploits of a new and entirely imaginary hero. *Amadis* was finished, and a long list of similar romances added to it, by subsequent Spanish and Portuguese writers. In these, while adventures became more and more marvellous, the fanciful spirit of chivalry was more and more carried into wild exaggeration. They became, however, so popular as to be transplanted into most European languages, and even in France to supersede the heroic tales of Arthur and Charlemagne. They declined with the advance of a better taste in literature after the art of printing had been for some time introduced; and were finally driven out of fashion by the wit of Cervantes, whose *Don Quixote* is aimed in great measure against them.

Meanwhile, a new species of fiction had acquired vogue in Italy, to which the term *novel* was first applied. This was the amorous or humorous tale; of which the *Decameron* of Boccaccio contains the earliest, and by far the most popular collection. The stories were derived from many originals; but especially from the *fabliaux*, of which mention has been already made. The Italian Novellieri are extremely numerous; but their compositions are always short, and would, in our modern language, be designated by the term *tale*, rather than novel or romance. They flourished in the 15th and 16th centuries. From these, again, was derived the comic satirical tale of Spain; a more sustained and longer class of composition, of which *Lazarillo de Tormes* and *Guzman d'Alfarache* are the best known specimens. But in these, which were also caricatures of the chivalrous romances, a long course of independent exploits of the hero formed the substance of the work, and not a story possessing an individual point and interest.

Don Quixote, of which the first part was published in 1609, was the joint result of the romances of chivalry, which it was intended to ridicule, and of the romances of low life, of whose character it contains a large intermixture. Although Cervantes had more in view, perhaps (the satirical object of his writing), than the direct delineation of manners and occurrences, such as we now expect in a novel, yet it may be fairly said that his immortal work is the first of its kind in which human nature is brought on the stage alike unadorned and undegraded; neither exaggerated by the ridiculous costume of chivalry, nor lowered by the familiar buffoonery of a comic tale. While, therefore, it has been the source of numerous imitations in its satirical character, its wide popularity has produced much more lasting effects in another manner: it gave the first example of a work of fiction in which the grave and gay events of life might be mingled together; and in which, also, the views and sentiments of the author might be conveyed through the medium of fictitious personages and events.

On the other hand, the chivalrous romance had been seized, at an earlier period, by a very different genius from that of Cervantes, and applied to another object. The fictions of Rabelais (the *Histories of Gargantua and Pantagruel*) cannot be termed romances; but their popularity was so great, that France was inundated for more than a century afterwards with Rabelaisian tales; and many of the elements of the modern low romance, comic hyperbole, eccentric humour, and much freedom and grossness of delineation, have been undoubtedly derived to us from Rabelais and his admirers. Swift and Sterne were both essentially imitators of this singular genius.

In the 17th century, Le Sage naturalized the Spanish romance in France. His works present a singular mixture of different styles, although all derived from the same country. In *Gil Blas*, for example (if that work be not actually of Spanish origin), we have something of the humour of *Don Quixote*, the form as well as much of the substance of *Guzman d'Alfarache*, &c.; and much intermixture of a class of tales of love and intrigue, which, coming originally from the Italian novellieri, had acquired a certain chivalrous colouring in passing through the hands of Spanish imitators. There is, moreover, a touch of French taste and philosophy, such as afterwards, when mixed with satire, gave birth to the modern philosophical tale or romance, of which Voltaire's writings contain the best known specimens.

After Le Sage, a new class of romances suddenly grew into fashion in France, the heroic; derived, indeed, in part from an earlier source, the pastoral romance of the 16th century. Of these, the *Clelie* and *Cassandre* of Mademoiselle Scudery were among the most popular examples, although they have long ceased to be read. This species of composition was, in fact, a revival of the old chivalrous romance, without its supernatural marvels, but with even greater exaggeration of sentiment. Its temporary success is rather to be attributed to a caprice of fashion than to the natural progress of taste. It was not, however,

wholly without its use, as it called back some degree of sentiment and high feeling into the romance, which was in danger of degenerating wholly into a comic cast.

During the 18th century, the romance and novel enjoyed a popularity, both in England and France, which threw comparatively into the shade every other species of fictitious literature. It would be impossible to continue such a sketch as the present, so as to trace out the various styles and species of those compositions which grew into vogue by the success of distinguished writers in each respective branch. In England, Richardson transferred into ordinary life somewhat of the refined sentiments which distinguished the heroic romance, and thus formed the basis of the modern English novel, properly so called, or novel of manners. His *Pamela* appeared in 1740; his last work, *Sir Charles Grandison*, in 1753. Fielding and Smollett, about the same time, revived the old comic romance, adapted to English scenes and characters. Sterne did the same by the humorous or Rabelaisian style of writing; but added an intermixture of pathos which had certainly never been joined before with so incongruous a companion. To these four writers, in conjunction with Goldsmith's *Vicar of Wakefield*, confessedly an independent original, almost all the English fictitious prose literature of the last century which is not imitated from foreign works may be said to owe its existence. In France, Marivaux, Prévost, and, with a worse taste than theirs, the younger Crébillon, formed the national manner in this class of writing for some time. Their productions have much of the same character with those of Richardson; but a far lower tone of morality, and less life-like description. But the popularity of the famous *Nouvelle Heloise* gave a new turn, not only in France, but over Europe, to the public taste in this branch of writing. Marivaux and Prévost may be said to have been Rousseau's models, as to the externals of his great romance; but its tone and sentiment are peculiarly its own. In France, after many inferior imitators, Madame de Staël, the first of female novelists, must be classed as the best and latest disciple of the school of Rousseau. In Germany, his style had even greater success; and he may be said to have called into life at once the taste and the power of that people and literature for fictitious composition. Wieland, Kotzebue, Goëthe (*Sorrows of Werther* and *Wilhelm Meister*), are all, though with much originality of their own, essentially followers of Rousseau; Lafontaine, and many other inferior writers, more direct imitators.

In our own times, while the novel of manners continues to maintain its empire in popular estimation, another species of romance—the historical—has likewise acquired a most powerful hold on the public taste, which, even more than the first, is chiefly of English original. The historical romance, in which fictitious scenes and personages are made to serve as vehicles for the historical portraiture of past times, had, especially in Germany, been cultivated with success before the writings of Sir Walter Scott; but it is to his adoption of this branch of composition, and the extraordinary talent which he devoted to it, that its present popularity and universal imitation are entirely owing.

ROMANCE'RO. In Spanish, the general name for a collection of the national ballads or *romances;* so called from the Roman or Romanic tongue, which, in the early part of the middle ages, seems to have been the common appellation of all the dialects spoken from the Alps to the western extremity of the Mediterranean. The *Romancero General*, the most celebrated of these collections, was published in 1604-14.

ROMANE'SQUE. (Fr.) In Painting, appertaining to fable or romance. In historical painting, it consists in the choice of a fanciful subject, rather than one founded on fact. The *romanesque* is different from *romantic;* because the latter may be founded on truth, which the former never is.

Romanesque, in Literature, is applied to the common dialect of Languedoc and some other districts in the south of France, which is a remnant of the old *Romanee* language, now nearly extinct. This term must not be confounded with *Romaic*, which is used to signify the language of modern Greece.

RO'MAN ORDER. *See* COMPOSITE ORDER.

RO'MAN SCHOOL. This school of painting, which, like the Florentine, addressed itself to the mind, is formed upon antique models. Its style was poetical; embellished with all the grandeur, pathos, and freedom from common matters, that the happiest imagination could conceive. In touch its masters were easy, correct in drawing, learned and full of grace. In composition it is sometimes whimsical, yet always elegant. The heads of the figures are always drawn with great respect to truth and expression, and it exhibits great intelligence in contrasting attitudes. It is in colouring that it displays the greatest marks of negligence, whilst in draperies it is eminently successful. At the head of this school was Raffaelle; and among its other principal masters were Giulio Romano, Zuccaro, M. A. Caravaggio, Baroccio, Andrea Sacchi (perhaps the best colourist of this school).

ROMA'NTIC, ROMANTICISM. By *romantic* is understood that singular intermixture of the wonderful and the mysterious with the sublime and beautiful which introduces us into an enchanted existence, and raises us above the bare realities of life by its dazzling peculiarities. Antiquity was a stranger to this feeling, nor had the classic languages any term to express it. *See* CHIVALRY.

Almost all authors concur in the difficulty of giving a precise signification to the term *romantic*. The *Dictionnaire de l'Academie Francaise* says, "Le romantique est un genre nouveau. *Romantique* se dit encore des écrivains qui affectent de s'affranchir des regles de composition et de style établies par l'example des auteurs classiques." This definition, though far from being precise, is perhaps the best that has hitherto been given; and instead of attempting to rival it, we shall content ourselves with placing it before the reader.

The term *romanticism*—an offshoot of romantic—is of recent invention, and is applied chiefly to the fantastic and unnatural productions of the modern French school of novelists, at the head of which are Victor Hugo, Balzac, "George Sand," &c., and their imitators in France and other countries.

ROMAN VITRIOL. Sulphate of copper, or blue vitriol.

ROMANZIE'RI. In Italian Literature, a series of poets who took for the subject of their compositions the chivalrous romances of France and Spain; and, with one or two exceptions only, those relating to the exploits of Charlemagne and his fabulous Paladins. The earliest of these poets flourished in the latter end of the 15th century. Boiardo, although not absolutely the first in order of time, is considered as having laid the groundwork, in his *Orlando Innamorato*, of the edifice of fiction raised by his successors. Pulci, in the *Morgante Maggiore*, was the first who allied the romantic incidents and sentiments of chivalry with light and humorous satire. Berni remodelled the work of Boiardo. Ariosto, in the *Orlando Furioso*, carried this species of poetry to the highest degree of perfection. These are the four principal Romanzieri; but many other poets of the same school flourished until the end of the 16th century. Tasso composed one of his early poems (*Il Rinaldo*) on the common model. In the beginning of the 18th century, the Abate Fortiguerra compiled his *Ricciardetto*, a poem of a semi-burlesque character, intended originally as a parody, but completed as a serious composition; and thus closes the list of the Romanzieri. All these poets adopted the ottava rima, invented by Boccaccio (*see* OTTAVA RIMA). In their poems the thread of the main narration is frequently interrupted by a multiplicity of minor adventures and intrigues; and this complication of plot appears to have constituted one of the characteristic features of the chivalrous epic. In most of them (from the time of Pulci) each book begins with a sort of prologue, more or less connected with the subject which follows: and these prologues form perhaps the greatest charm of the poem of Ariosto; effecting the transitions from one subject to another by means of some touch of pathetic or elevated reflections, or of light humour and playful satire, generally in the form of an address to the supposed audience, the poem being framed on the model of a tale recounted by a minstrel to an assembly of knights and ladies.

ROMA'NZOFITE. A mineral from Finland of a brown colour; it is a triple silicate of lime, alumina, and iron.

RO'NDEAU. (Fr.) In French Poetry, a little poem of thirteen verses, divided into three unequal strophes, with two rhymes (eight lines masculine and five feminine, or *vice versâ*). The two or three first words of the first verse serve as the burden, and recur in that shape after the eighth and thirteenth verses. There are also double rondeaux and single rondeaux; the latter an obsolete, but easier kind of verse. In Music, the term *rondeau* is applied to a light air, in which the first strain forms the burden, and as such is frequently repeated: it is also written *rondo*.

RO'NDEL. In Fortification, a small round tower, erected in some particular cases at the foot of the bastion.

ROOD. (Ang. Sax. rode, *beam;* used for the Cross.) The crucifix, sometimes also the image of a saint, was so called in old English churches. Roods were set in shrines or tabernacles, and the place where they stood was called the rood-loft, which was commonly over or near the passage out of the body of the church into the chancel. They were all ordered to be taken down in 1548 (Burnet, *Hist. of the Reformation*, vol. ii. book 1.); but restored for a short time under Queen Mary. (*Archæologia*, vol. i.)

ROOD. A square measure, the fourth part of a statute acre, and equal to 40 perches or square poles.

ROOF. In Architecture, the uppermost part of a building, containing the timber work, with its covering of slate, lead, tile, or other material. Carpenters, however, restrict their use of the word to the timber framing alone.

The inclination of the sides of a roof will, considering the species of covering to be the same in all, depend very

much on the temperature of the country to which it is to be adapted. In the southern countries of Europe roofs do not require much elevation, whilst as we proceed northward they require a far greater pitch. In the warm, or rather hot climates, buildings require nothing more than a terrace for their covering; but in the temperate climates, wherein the latitude exceeds 42 degrees, experience shows that the flat covering of a building cannot be practised with any expectation of durability. The rains of hot climates are violent, whilst those of temperate climates are searching. In the more northern latitudes the moisture, the driving nature of the rain, and, in addition, the duration of the snow on the roofs, require, it is obvious, a more considerable inclination. Such materials as lead, copper, zinc, and the like, which, supposing them one piece, as, in fact, when used, they ought to be, are not fair examples from which to draw inferences in the theory whereof we speak; for, if well executed, they must either of them be considered as one homogeneous piece: but in the case of tiles, whether of marble, stone, or clay, the case is far different. Without entering minutely into the details of this subject, we will merely observe, that supposing the inclination of a roof to be zero at the equator, if we add to it an inclination of three degrees for every climate from the equator to the polar circle, each climate being taken at 2° 42′ 30″, we obtain results which show that the roofs and pediments of temples of antiquity must have been well studied in that useful point of view which regarded their durability and impenetrability by rain. The *Encyc. Met.* we believe to have been the first instrument of promulgating this curious theory; and believing in it as we do, we can, if it be not true, only use the Italian saying, "si non è vero, è ben trovato." The theory would give an inclination to roofs at Athens of 16¼ degrees, and they are very nearly so inclined; the temple of Minerva being 16 degrees, and that of the temple of Eretheus 15½ degrees. In Rome, according to this theory, the inclination of a roof, and consequently pediment, should be 22 degrees; and experience finds it varying from 23 degrees to 24½. The advocates for the propriety of strictly copying Greek forms and details under the latitude of London will, if they have studied the æsthetics of the art, find no little difficulty in establishing their doctrines, after weighing this matter impartially. But our limits prevent further observation; we will merely subjoin a table conformable to the theory: —

Place.	Latitude to nearest Minute.	Length of longest Day.	Inclination of Roof, supposing Covering to be Roman Tiles.
Carthagena -	37° 36′	14h. 42m.	19° 12′
Palermo - -	38 7	14 48	19 48
(Latitude of Athens is 38° 5′)	- -	- -	(see above.)
Lisbon - -	38 42	14 50	20 0
Madrid - -	40 25	15 0	21 0
Naples - -	40 50	15 2	21 12
Rome - -	41 54	15 10	22 0
Paris - -	48 50	16 6	27 36
London - -	51 31	16 34	30 24
Amsterdam -	52 22	16 44	31 24
Edinburgh -	55 57	17 32	36 12
Petersburgh -	59 56	18 44	43 24

A roof, as respects its construction, involves some knowledge of mathematics. Of the general principles on which its proper construction depends, we shall here subjoin some account. The obvious mode of covering a building, where a greater or lesser inclination of the sides of the roof is required by the climate, is to place two sloping rafters C C upon the walls B B, as in the subjoined diagram (fig. 1.), meeting at the apex A; where we will suppose them so connected with a hinge as to be inseparable, but capable of descending by their gravity, as shown in No. 2. The walls are considered as solid masses, moveable on points P. If the walls be not of sufficient weight, the thrust that will be thus exerted on them by the tendency of the rafters to spread at their feet will throw the walls out of an upright, as in No. 2., and the whole assemblage will be destroyed. By the laws of mechanics, it is known that the horizontal thrust thus acting on the walls is proportional to the length of a line *de*, drawn at right angles to the rafter, intersecting a vertical line drawn from the apex, which it is manifest must increase as the roof becomes flatter. To counteract the thrust above mentioned, nothing more is necessary than to tie together the feet of the rafters, as in the following diagram (fig. 2.); in which A B is the tie in question, and thence is called a *tie-beam*. If the extent be not very great, the rafters may be kept from spreading by a minor tie, as at *a b*, called a *collar*. Beyond certain lengths or spans, however, it will occur to the reader that a tie-beam will itself have a tendency to bend, or sag, as the workmen call it, in the middle; and from this circumstance a fresh contrivance becomes necessary, which will be seen in the diagram below (fig. 3.), marked *c d*: this is called a *king post*, or more properly *king-piece*, inasmuch as it does not perform the office of a post, but rather of a tie, for it ties up the beam to prevent its bending. If the rafters be so long as to be liable to bend, two pieces *a a*, called *struts*, are introduced; which, having their footing against the sides of the king post, act as posts to support or *strut up* the rafters at their weakest points. The piece of framing thus contrived is altogether called a *truss*. It is obvious that by means of the upper joints of the struts we obtain more points of support (fig. 4.), or rather suspension; and that but for the compressibility of the timber, there would be no limit to the space which a roof might be made to cover. This compressibility takes place at those points where the fibres of the wood are pressed at right angles, or nearly so, with their direction, and many ways are adopted for avoiding this inconvenience. There is a species of roof, dependent in construction on the principles we have just described, which we shall here briefly notice, and whereof the following is a diagram (fig. 5.). This roof has three points of support, A, B, A; the posts A A, A A are called *queen posts;* the collar A B A is here a *straining piece*, instead of a tie, as it was in the example of ties first noticed, its operation being exactly the reverse of a tie. The *curb* or *mansard* roof is one in which a story is obtained, as may be seen in the annexed diagram (fig. 6.). Its principles are the same as those already mentioned, and do not here require further notice. In the execution of roofs the expense of trussing every pair of rafters would be unnecessary, and the practice would also load the walls with a far greater weight than would be expedient; it is therefore the custom to place these *principal* parts of a roof at certain intervals, which, however, should never exceed ten feet. The rafters which are actually trussed are called *principal rafters;* and by the intervention of the *purline* A in the diagram (fig. 7.), are made to bear the smaller or common rafters, which are notched down on it. These common rafters are received by or pitch upon a plate B, called a *pole-plate;* and the principal rafters, which fall on the tie-beam, are ultimately borne by the wall-plate C. When beams, in either roofs or floors, are so long that they cannot be procured in one piece, two pieces to form the required length are *scarfed* together, by indenting them at their joints and bolting them together; of which practice two modes are here subjoined (fig. 8.).

(8.)

ROOK. The name of a well-known species of crow (*Corvus frugilegus*, Linn.), resembling in size and colour the carrion crow, but differing in having the base of the bill whitish and scurfy, and bare of feathers. "This," says Montague, "is acquired by the bird's habit of thrusting its bill into the ground after worms and various insects. The rook is content with feeding on the insect tribe, particularly the larvæ of the cockchaffer; and while following the plough to remove from the newly-made furrow this destructive grub, it more than repays the husbandman for the grain which it may afterwards pick up. The rook is gregarious at all seasons, resorting constantly to the same trees every spring to breed, when the nests may be seen crowded one over another upon the upper branches. It lays four or five eggs, much like those of the crow, of a greenish colour spotted and blotched with dusky. After their young have taken wing, they all forsake their nest-trees, returning to them again in October to roost; but as winter comes on, they generally select more sheltered places at night in some neighbouring wood, to which they fly off together." (Montague, *Ornithological Dictionary*.) The wood or grove of tall trees, in which rooks congregate and build their nests, is called a rookery.

ROOT. In Arithmetic, a number which being multiplied into itself any number of times produces another number, called a *power*, of which power the original number is the root. The root takes the name of the power whose root it is. Thus, it is called the *square root*, if the power is a square; the *cube root*, if the power is a cube, and so on.

ROOT. That part of the central axis of a plant which is formed by the descending fibres, and whose function is

to attract liquid food from the soil in which it is mingled. It differs from the stem in not having leaves or buds upon its surface, and in its tendency to burrow under ground, retreating from light; nevertheless, some kinds of roots are exclusively formed in air and light, as in the ivy, and other such plants.

ROOT OF AN EQUATION, in Algebra, signifies the value of the unknown quantity which enters into the equation. *See* EQUATION.

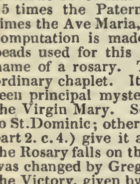
ROO'TSTOCK. In Botany, a prostrate rooting thickened stem, which yearly produces young branches or plants. It is common in *Iridaceæ* and Epiphytous *Orchidaceæ*, and is often confounded with the root. Ginger and orris root are common instances of it.

ROSA'CEÆ. (Rosa, one of the genera.) A large and important natural order of plants, the species of which are for the most part inhabitants of the cooler parts of the world. They are in some cases trees, in others shrubs, and in a great number of instances herbaceous perennial plants; scarcely any are annuals. No natural orders contain more species of general interest, in the beauty of their flowers or their perfume: there is the rose itself, and various species of the genera *Rubus*, *Spiræa*, *Potentilla*, *Geum*, and *Pyrus*. The apple, pear, plum, cherry, peach, nectarine, apricot, and similar valuable fruits, are the produce of others. The white thorn, with all its numerous exotic allies, belongs to the genus *Cratægus*. As medicinal plants, some are of considerable importance The root of *Potentilla reptans*, *Geum urbanum*, and others, is powerfully astringent; the bark of *Prunus coccomilia* has some reputation as a febrifuge; an Abyssinian plant called *Brayera anthelmintica* has energetic vermifugal qualities; and finally, prussic acid is obtained from the leaves and seeds of the almond, peach, plum, and other related species. This important assemblage of plants is distinguished by having several petals; separate carpels; distinct, perigynous, numerous stamens; alternate leaves, and an exogenous mode of growth.

RO'SARY. (Lat. rosarium, *a rose-bed.*) A Roman Catholic devotional practice; which consists in reciting 15 times the Paternoster, or Lord's Prayer, and 150 times the Ave Maria, or angelical salutation; but as the computation is made by means of beads, the string of beads used for this purpose has acquired the popular name of a rosary. The rosary is thus three times the ordinary chaplet. It is instituted in honour of the fifteen principal mysteries in the life of our Saviour and the Virgin Mary. Some have attributed its institution to St. Dominic; others (among whom is Mosheim, cent. x. part 2. c. 4.) give it a higher antiquity. The festival of the Rosary falls on the first Sunday in October. Its name was changed by Gregory XIII. from that of St. Mary of the Victory, given by Pius V. on its original institution in honour of the battle of Lepanto, which took place on that day.

ROSE. (Lat. rosa.) In Botany, the English name for the well-known and universally cultivated flower of the genus *Rosa*. (*See* ROSACEÆ.) It would occupy too much space to point out even cursorily the various ceremonies in which this flower plays a distinguished part; suffice it to say, that in the earliest ages it was regarded with even more favour than at the present times, and both at public and private festivals was considered an indispensable ingredient. (See the *Damen Lexicon.*) In architecture, the sculptured representation of this flower is found in the centre of each face of the abacus in the Corinthian capital, and is called the rose of that capital. Roses are also used to decorate the caissons in the soffitts of coronas and ceilings.

ROSE ENGINE. In Mechanics, an appendage to the turning lathe, by which a surface of wood or metal, as a watch-case, is engraved with a variety of curved lines. The assemblage of these lines presenting some resemblance to a full-blown rose, is called by the French *rosette;* and hence the engine by which the ornament is produced is called a rose engine. The mechanism by which the figures are produced is sometimes called a *camb*, and may be described as follows: "A wheel upon the axle C turns uniformly in the direction A B D E. A rod *m n* moves in guides, which only permit it to ascend and descend perpendicularly. Its extremity *m* rests upon a path or groove raised from the face of the wheel, and shaped into such a curve that as the wheel revolves the rod *m n* shall be moved alternately in opposite directions, through the guides, with the required velocity. The manner in which the velocity varies will depend on the form given to the groove or channel raised upon the face of the wheel; and this may be shaped so as to give any variation to the motion of the rod *m n* which may be required for the purpose to which it is to be applied." (*Lardner's Mechanics*, *Cab. Cyclopedia*, p. 250.)



The purpose of the machine is therefore to convert a uniform rotatory movement into a varied rectilinear and alternating movement. It is also used in machinery for spinning, and for lace-making.

ROSEMARY (Lat. ros marinus, *sea dew*), is the name given to a small evergreen shrub of the Labiate order, which inhabits rocky hills in the neighbourhood of the Mediterranean, and which is commonly cultivated in our gardens. It has very narrow green leaves, turned back at the edge and hoary underneath. The flowers are of a dull leaden blue, or even white. It has been employed in infusion as a remedy for headache, and is extensively employed in the manufacture of pomatums for promoting the growth of hair. Oil of rosemary is what gives the green colour to these preparations. It is also said to be one of the ingredients in Eau de Cologne. Narbonne honey is also said to owe its peculiar flavour to bees feeding on the blossoms of the rosemary. The grey bushes, mantled with dew drops, on the rocky coasts of France and Italy, are said to justify the singular name that has been given to the plant. It is the *λιβανωτὶς στεφανωματικὴ* of Dioscorides.

ROSE-NOBLE. A gold coin of the value of 6*s*. 8*d*., first coined in the reign of Edward III.

ROSEO'LA, called from its rose colour a *rash;* frequently symptomatic of different febrile complaints, of disordered stomach and bowels, of teething, and of any constitutional irritation. Acidulated drinks, mild aperients and sudorifics, and strict attention to the diet, with caution against the application of or exposure to cold, so as to cause a retrocession, are the principal points to be attended to.

ROSES, FESTIVAL OF. A rural festival of some parts of France, in which the best-behaved maiden of the town or village (called *La Rosiere*) is annually crowned with roses in the church, whither she is conducted with great pomp by the villagers. These festivals were originally celebrated on the 8th of June at Salency, a village of Picardy, under Louis XIII.; but they were afterwards introduced into Surêne, near Paris, whence they extended to many other places, and have latterly even penetrated to Moravia. The Persians have also an annual festival of roses, which consists of bands of youth parading the streets with music, and offering roses, as the Italians during the carnival *confetti*, to all they meet, for which they receive a trifling gratuity.

ROSES, WHITE AND RED. In English History, the well-known feuds that prevailed between the houses of York and Lancaster are so called, from the emblems adopted by their respective partisans; the adherents of the house of York having the white, those of Lancaster the red rose, as their distinguishing symbol. These wars originated with the descendants of Edward III.; and after extending over a period of more than eighty years, during which England formed an almost uninterrupted scene of bloodshed and devastation, were finally put an end to by the victory of Henry Tudor, earl of Richmond, over Richard III. in 1485, the victor uniting in his own person the title of Lancaster through his mother, and that of York by his marriage with the daughter of Edward VI. Since that period the rose has been the emblem of England, as the thistle and shamrock (see those terms) are respectively the symbols of Scotland and Ireland.

ROSE'TTA STONE (so called from Rosetta, a village of Egypt, where it was discovered by the French). The name given to the celebrated stone, now in the British Museum, which has played so distinguished a part in all modern hieroglyphical researches. It is a piece of black basalt, three feet in length, and about two feet and a half in breadth, and contains parts of three different sculptured inscriptions: one in sacred characters, or, as they are termed, *hieroglyphics;* the second in enchorial characters (*i. e.* in those of the country, or in modified conventional hieroglyphics); and the third in Greek. From the last, or Greek inscription, it appears that the inscriptions are either entirely or substantially identical, and form a royal decree which was ordered to be sculptured in the languages above specified. The inscriptions are a good deal mutilated, particularly the hieroglyphical; but they are still sufficiently distinct to allow the hieroglyphical and enchorial characters to be compared with each other and the Greek. As the discovery of this stone presented to the learned the first opportunity of viewing the Greek in juxtaposition to the Egyptian language, great hopes were entertained that a key would thereby be obtained to the deciphering of the numerous monuments of ancient Egypt. It would appear, however, from the investigations of Dr. Young and Champollion, whose attention has been deeply engrossed with this subject, that the Greek does not faithfully represent the enchorial text, but gives merely its substance. According to the Greek inscription, the stone was erected in the reign of Ptolemy Epiphanes

(A. C. 194), whose benevolence it describes, and enumerates his victories and the principal political transactions of his reign. *See* HIEROGLYPHICS.

ROSICRU'CIANS. A sect of visionary speculators who existed in Germany about the beginning of the 17th century. They ascribed, indeed, a much higher antiquity to themselves; but it is probable that if any body of philosophers who adopted this title ever existed in reality, they were the alchemists, fire-philosophers, or Paracelsists of the 16th century, who adopted this mode of giving vogue and fashion to their tenets. Germany was inundated with tracts, from 1600 to 1630, purporting to come from supporters or from enemies of this sect, in which their opinions and intentions are canvassed, but generally in a wild and unintelligible manner. From one of these, a *Treatise on the Laws of the Rosicrucians*, by Ritter von Maier (1618), we learn that the fraternity had six fundamental laws: — 1. That their chief end and object was to cure the sick without fee or reward. 2. That in travelling they were to change their habits and dress, so as to accommodate themselves to those of the countries in which they sojourned. 3. To meet once a year on a certain day and at a certain place, kept secret from the rest of the world. 4. To fill up vacancies in their body by electing fresh members. 5. To use the letters R. C. as their common symbol. 6. That the fraternity should remain undivulged for one hundred years from its foundation. It appears probable that the device of the rose issuing out of the cross, which was the same with Martin Luther's seal, was adopted for the purpose of attracting the notice of the religious: the rose was explained to represent the blood of Christ. It would appear from these laws that some species of secret Freemasonry was intended; and the Rosicrucians have been by some connected with the Freemasons; but there is, in point of fact, no evidence that any such society existed at all, and the name and other circumstances were probably only the device of some alchemists, who usually conveyed their own notions under cover of symbolical language. Andreä, a German scholar, is stated, in the *Conversations Lexicon*, to have been the original propagator of the reports concerning the Rosicrucian society. The Rosicrucians have been also connected in various ways, by public opinion, with the Cabalists, Illuminati, &c.; and the division of spiritual beings inferior to the angels into sylphs and gnomes, which furnished Pope with the machinery of the *Rape of the Lock*, is of Rosicrucian or Cabalistic origin. It is found in that singular work, the *Comte de Gabalis*, which obtained a sudden popularity in the beginning of the last century; in which the author professes himself a member of the Rosicrucian fraternity. (See Mosheim, *Eccl. Hist.* vol. v.)

ROSIN. *See* RESIN.

ROSTE'LLUM. (Lat. rostrum.) An elevated and rather thickened portion of the stigma of Orchidaceous plants, from which the peculiar gland separates by which the pollen masses of some species of that order are eventually held together. It was formerly supposed to be the point through which impregnation is effected; but this is now known to have been an error.

ROSTELLUM. The name of the mouth of the louse and similar Apterous insects, in which the ordinary trophi are replaced by an exarticulate retractile tube, from which a retractile siphuncle is protruded. The uncinated proboscis of the tape-worms (*Tæniæ*) is also so called.

ROSTER, in Military affairs, is applied to the plan or table by which all military duty is regulated.

RO'STRULUM (Lat. dim. of rostrum), in Entomology, is the name of the oral instrument of the flea and other *Aphanipterans;* in which the ordinary trophi are replaced by a bivalved beak, between the valves of which there are three lancet-shaped instruments.

ROSTRUM. (Lat.) Literally the prow of a ship, but metaphorically applied to the pulpit or pleading place in the Roman forum, which was decorated with the prows of vessels taken from the enemy. (See *Niebuhr's Roman History.*)

ROT. A term applied to a well-known disease peculiar to sheep. It is often called *great rot*, and *hydrophic rot*, &c.; but it is more popularly known by the single term of rot. Many causes have been assigned for it; as the *Fasciola hepática*, or fluke worm; some particular plants eaten as food; ground eating; snails, and other ingesta: but as most of the supposed deleterious herbs have been tried by way of experiment, and have failed to produce the disease, so it is attributable to some other cause. Neither is there satisfactory reason to suppose that the fluke worm is the original cause of it, but a consequence; since we know that the biliary vessels of other animals, as horses, asses, rats, &c., often have them: and above all, because that they are not always present in the rotted subject. From long experience, and the almost invariable effect produced by a humid state of atmosphere, soil, and product, we are warranted in concluding these are the actual and immediate agents: perhaps the saturated food itself is sufficient to do it. The morning dew has been supposed equal to it. Bakewell, when his sheep were past service, used to rot them purposely, that they might not pass into other hands. This he always readily did by overflowing his pastures. But great differences of opinion exist as to the quantity, form, and varieties of moisture productive of this fatal disease. It is said that land on which water flows, but does not stagnate, will not rot, however moist; but this is contradicted by the experience of Bakewell, who used merely to flood his lands a few times only to rot his sheep. It is also said they are safe from rot on Irish bogs, salt marshes, and spring-flooded meadows, which experience seems to verify. It is also said that the very hay made from unsound land will rot; but this wants confirmation. When salt marshes are found injurious, it is only in years when the rain has saturated or rather super-saturated such marshes. That putrid exhalations unaccompanied with moisture can occasion rot wants confirmation also; for these commonly go together, and it is difficult to separate their effects. It is not, perhaps, the actual quantity of water immediately received by land, but the capacity of that land to retain the moisture, which makes it particularly of a rotting quality.

The signs of rottenness are sufficiently familiar to persons about sheep. They first lose flesh, and what remains is flabby and pale; they also lose their vivacity. The naked parts, as the lips, tongue, &c., look livid, and are alternately hot and cold in the advanced stages. The eyes look sad and glassy, the breath is fetid, the urine small in quantity and high-coloured; and the bowels are at one time costive, and at another affected with a black purging. The pelt will come off on the slightest pull in almost all cases. The disease has different degrees of rapidity, but is always fatal at last. This difference in degree occasions some rotted sheep to thrive well under its progress to a certain stage, when they suddenly fall off, and the disease pursues the same course with the rest. Some graziers know this crisis of declension, as it has been called, and kill their sheep for market in the immediate nick of time with no loss. In these cases, no signs of the disease are to be traced by ordinary inspectors; but the existence of the flukes, and still more a certain state of liver and of its secretions, are characteristic marks to the wary and experienced.

The treatment of rot is seldom successful unless when it is early commenced, or when of a mild nature. A total change of food is the first indication, and of that to a dry wholesome kind: all the farinæ are good, as the meals of wheat, barley, oats, peas, beans, &c. Carrots have done good, mixed with these: broom, burnet, elder, and melilot, as diuretics, have also been recommended; but it is necessary to observe, that there is seldom any ventral effusion but in the latter stages of the complaint. As long as the liver is not wholly disorganized, the cure may be hoped by a simple removal of the cause, which has been shown to be a variable temperature, with excessive moisture of pasturage, which may also be aided by such remedies as assist the action of the biliary system. Salt acts in this way, and thus salt mashes are good: salt may also be given in the water. Salt appears the principal ingredient in Flesh's patent restorative for sheep; for it states it to be composed of turpentine, sal ammoniac, turmeric, quicksilver, brimstone, *salt*, opium, alkanet root, bark, antimony, camphor, and distilled water; but of this medley none of the articles can be in sufficient quantity to prove useful but the salt. In the more advanced stages of the disease, when the liver has become materially affected, it is prudent to rub the belly of each sheep with half a drachm of mercurial ointment every other day for a week. Give also the following every morning: — Watery tincture of aloes, half an ounce; decoction of willow bark, four ounces; nitric acid, twenty-five drops. (*Loudon's Ency. of Agriculture.*)

ROT. In Timber. *See* DRY ROT.

ROTA'TION. (Lat. rota, *a wheel.*) In Mechanics, the motion of a solid body about an axis. Rotatory motion is distinct from progressive motion, though both are frequently found to coexist in the same body. The planets, for example, at the same time that they have a progressive motion in their orbits, revolve also about axes passing through their respective centres of gravity. It is the rotatory motion of the earth about its axis which produces the alternations of day and night; and a slow but constant change of position in that axis, arising from the attraction of the sun and moon on a body not absolutely round, gives rise to the astronomical phenomenon of the precession of the equinoxes.

The determination of the circumstances of the rotation of a planet about its axis is a problem of physical astronomy, not less interesting or important than that of the planet's motion in its orbit. It was, in fact, long considered as the more difficult problem of the two; but, according to the methods of modern analysis, both form a part of the same theory, and their solutions are deduced from the same general equations of motion.

In relation to practical mechanics, the problem of rotation is also of great importance; inasmuch as it comprehends the methods of computing the performance of

machines, the forces necessary to overcome their inertia, and the proper relations and most advantageous disposition of their several parts, in order that the required effect may be produced by the smallest expenditure of power and the least strain or injury to the machine itself.

In all investigations relating to the motion of bodies about axes, the terms *moment of force*, *moment of inertia*, *angular velocity*, are of constant occurrence; it is therefore important to keep in view the exact meaning of those terms.

The *moment of a force* exerted in turning a body about an axis, is the product obtained by multiplying the force into the perpendicular from the axis upon the line of its direction; or it is the force multiplied into the leverage. Thus, if F be force supposed to act in a plane perpendicular to the axis, and h a line drawn from the axis perpendicular to the direction of the force, the moment of the force is $\mathrm{F}h$. But as force is measured by the velocity which it communicates to a given mass, this is usually expressed by $\mathrm{M\,V}h$; where V is the velocity which the force F communicates to the mass M, when directed to its centre of gravity, in the time which is assumed as unity.

The *moment of inertia* of a body in respect of a given axis, is the sum of all the products obtained by multiplying each element of the body into its distance from the axis. Thus, if m be one of the constituent elements of the body, and r the distance of m from the axis, then the moment of inertia is $\Sigma r m$; the summation denoted by Σ being extended to every element m. *See* MOMENT.

The different particles of a solid body revolving about an axis move with a velocity proportional to their respective distances from the axis; and the velocity of the particle whose distance from the axis is unity is the *angular velocity* of rotation. If this be denoted by ω, then the velocity of a particle whose distance from the axis is r will be $r\,\omega$.

These definitions being premised, we may now state a few of the more remarkable properties of rotatory motion. If the motion is produced by impulse, and the moving body is not acted upon by accelerating forces, so that the velocity is uniform, the fundamental theorem (which is easily deduced from the property of the lever) is,

$$\text{angular velocity} = \frac{\text{moment of impelling force}}{\text{moment of inertia}}.$$

In the case of a body turning about a fixed axis, it is supposed that the impelling force acts in a direction perpendicular to the plane passing through the axis of rotation and the point at which the force is applied. If the impelling force is not perpendicular to this plane, it must be resolved into two parts, one of which is perpendicular to the plane, and the other parallel to it; and it is only the former part which tends to produce rotation, the latter being destroyed by the resistance of the axis.

When all the different particles of a body are acted upon by accelerating forces (as in the case of a pendulum drawn aside from the position of rest and abandoned to the action of gravity), the angular velocity becomes a variable quantity, and is expressed by this formula,

$$\frac{d\,\omega}{d\,t} = \frac{\text{moment of the impelling forces}}{\text{moment of inertia}};$$

where $d\,\omega$ is the element of the velocity, and $d\,t$ the element of the time. The moment of the impelling forces is computed from this expression, $\Sigma m\,v\,h$; where m is the mass of an element of the body, h its distance from the axis of rotation, and v the velocity due to the accelerating force. From the above formulæ, it is obvious that the computation of the moment of inertia must enter into every question connected with rotatory motion.

Principal Axes. — Generally speaking, any change which is made in the position of the axis about which a body revolves must be accompanied with a change in the moment of inertia. Hence, if a point (which is not the centre of gravity) be taken in a solid body, all the axes which pass through that point (and they may be infinite in number) will have different moments of inertia, and there must exist one in respect of which the moment is a maximum, and another in respect of which it is a minimum. Those axes in respect of which the moment of inertia is a maximum or minimum are called the *principal axes of rotation*.

If for any point taken in a solid body, we proceed by the usual methods of maxima and minima to find the position (relatively to the principal lines of the body) of that line or axis about which the moment of inertia is the greatest or least possible, the analysis leads to a cubic equation, of which all the three roots are real. Hence, for every point of a body, however irregular, there are *three* principal axes. Further examination shows that these axes form a system of straight lines at right angles to each other. One of them is such that the moment of inertia with respect to it is the least possible; with respect to another, the moment is the greatest possible; and although with respect to the third the moment is not, strictly speaking, the greatest or least, yet it possesses this characteristic of maxima and minima, that its differential coefficient is nothing, or its value is not affected by a very small change in the position of the axis.

If the form and structure of the revolving body be such that the moments of inertia about two of the principal axes are equal, then every line in the plane of those axes passing through their points of intersection will be a principal axis. For example, in the spheroid of revolution, the polar diameter forms one of the principal axes; the two others are in the plane of the equator, and consequently equal; and it is obvious from the symmetrical form of the body that every equatorial diameter will have the same moment of inertia, or be a principal axis. If all three principal axes are equal, as in the case of a sphere when the point in which the axes meet is the centre, then every line passing through the same point is a principal axis. From this it follows that with respect to any point taken in a solid body there are either three principal axes, or else an infinite number.

It is a property of the principal axes, that if a body begins to revolve about any one of them it will continue to revolve about the same axis uniformly and perpetually, unless the motion is deranged by the action of a disturbing force. The centrifugal forces about a principal axis exactly counterbalance each other, and the axis remains unmoved without the aid of any support. There is, however, an essential difference in this respect between one of the axes and the two others. If a body begins to revolve about an axis very near to one of the axes for which the moment of inertia is the greatest or least possible, the axis of actual rotation will continue to oscillate about that principal axis, never deviating from it beyond certain narrow limits, and the angular velocity will only suffer small periodic alterations; but if the body begins to revolve about an axis which is very near to the intermediate principal axis, the axis of rotation will deviate from the principal axis indefinitely, and the velocity of rotation will not remain constant. Hence the rotation about two of the principal axes is stable; about the third unstable.

When a solid body revolves about a fixed axis, there are certain points in the body having determinate situations with respect to the axis of rotation and centre of gravity, which, on account of their remarkable properties, require to be distinguished. Thus, in computing the effects of machinery, it is often necessary to determine the situation of the point at which if the whole mass of the revolving body were concentrated the rotatory effect would remain unaltered. This point is called the *centre of gyration*. The *centre of oscillation* of a body suspended by an axis is the point at which if all the matter were collected the oscillations would be performed in the same time. The *centre of percussion* is the point at which if the body encountered an immoveable obstacle the motion would be arrested without producing any strain on the axle. For the properties of these centres, and the method of computing their positions, see CENTRE.

Motion of a Body entirely free. — If a body is retained by no fixed point, but is at liberty to move in any direction, and if a force be applied to it in a direction which passes through its centre of gravity, all the points of the body move forward in straight lines parallel to each other and to the direction of the impelling force. But if the direction of the force does not pass through the centre of gravity, the body will acquire two motions,— one progressive, and the other rotatory; and these two motions are entirely independent of each other, that is to say, each is performed exactly in the same manner as if the other did not exist. The progressive motion is the same as if the direction of applied force had passed through the centre of gravity, and the rotatory motion communicated to the body is the same as if the centre of gravity had been a fixed point. In consequence of this property the general problem of determining the motions of a body subjected to the action of given forces resolves itself into two; of which the first is to determine the motion of the centre of gravity of the moving body, and the second to determine at every instant the position of the axis and the velocity of rotation.

In the solution of the latter problem the following elegant theorem, first given by Frisi, is of important use: — When a body revolves on an axis passing through its centre of gravity, and a force is impressed tending to make the body revolve about another axis also passing through its centre of gravity, the body will revolve about neither, but on a third axis, which lies in the same plane with the other two, and so situated as to divide the angle which they contain into two parts, such that the sines of the parts are to each other in the inverse ratio of the angular velocities with which the body would have revolved about the said axes respectively. It is evident that this conclusion will hold good if the angular motions about both axes are impressed simultaneously; and as the velocity about the new axis may in like manner be compounded with another velocity about a different axis, it follows that if several angular motions about given axes are impressed on a body at the same time, the position of

the resultant axis and the velocity of rotation may be readily computed.

If the primitive axes are at right angles to each other, then the square of the angular velocity about the resultant axis is equal to the sum of the squares of the velocities about the primitive axes. These properties form the theory of the composition of rotatory motion. For their demonstration the reader may be referred to *Airy's Mathematical Tracts*, "Precession" and "Nutation;" or to the article "Rotation," in the new edition of the *Encyclopædia Britannica*.

The principal application of the theory of the rotation of bodies entirely free is to the planets, and particularly the earth. It is to be observed, however, that the change which is continually taking place in the position of the terrestrial axis of rotation is only in respect of fixed points in space; for it can be shown that since the earliest recorded astronomical observations, the position of the poles of rotation on the earth's surface has undergone no alteration whatever.

The principal works on the subject are *Euler's Theoria Motus Corporum Solidorum*, 1765; Vince, *Phil. Trans.*, 1780; Frisii, *Opera*, tom. ii., 1783; *Atwood's Treatise on the Rectilinear Motion and Rotation of Bodies*, 1784; *Landen's Mathematical Memoirs*, 1789; Laplace, *Mécanique Celeste;* Lagrange, *Mécanique Analytique;* Poisson, *Traité de Mécanique*, &c.

ROTATION OF CROPS. In Agriculture and Gardening, it is found that the same annual crop cannot be advantageously cultivated on the same soil for more than one or two years; and hence one kind of crop is made to succeed another. And the number of cultivated crops being limited, when the whole course has been gone through once it is again repeated; and hence the origin of the word *rotation*. But as the same number and kind of crops are not always grown in regular succession, but a change is frequently made according to general principles, the term used in that case is *succession of crops*. The principle on which the succession of crops is founded is, that every kind of plant not only extracts nourishment from the soil, but exudes into it excrementitious matter, which is found injurious to that species, though it may prove nutritious to another species. As a general principle of guidance in determining the succession of crops, it is considered advantageous that a crop cultivated for its leaves or roots should succeed one cultivated for its ripened seeds; that the cereal grasses should be succeeded by leguminous plants; taprooted plants, or plants bearing tubers, by fibrous-rooted plants; and plants which form a compact covering on the surface, such as corn and legumes sown broadcast, by plants which only partially cover the surface, such as crops grown in rows sufficiently wide to admit of cultivation between. It may also be adopted as a rule, that where land is to be subjected to a crop of the same plants for a number of years, as in permanent pasture, the plants composing the crop should be of several different kinds, by which means the excrementitious deposit of one species becomes the nutriment of another. Hence the propriety of sowing clover, ribwort, and other taprooted dicotyledonous herbage plants among pasture grasses.

RO'TATORIES, *Rotatoria*. (Lat. rota, *a wheel.*) Wheel animalcules. *See* ROTIFERS.

RO'TIFERS, *Rotifera*. (Lat. rota, and fero, *I carry.*) The name of a class of highly organized Infusorial animals, outwardly distinguished by certain ciliated appendages at the anterior part of the body, which seem to move in a rapid rotatory manner, and by their superior size. They are commonly termed "wheel animalcules."

ROTTEN STONE. An earthy mineral found near Bakewell in Derbyshire, in Wales, and at Albany in New York. It is much used for polishing metals; and consists, according to R. Phillips, of 86 alumina, 10 carbon, and 4 silica. It resembles tripoli.

ROU'BLE. A Russian silver coin of different values. It was first struck at Moscow in 1654. Catherine II. caused some gold coins to be struck with this name; but they are no longer current. *See* MONEY.

ROUE'. In the *beau monde*, a person devoted to a life of pleasure and sensuality, but not so completely vitiated in his character and manners as to be excluded from society. The term is said to have been first used in this sense by Philip of Orleans, the regent of France.

ROUGE. A species of lake prepared from the dried flowers of the *Carthamus tinctorius*, or safflower. Rouge is the only cosmetic which can be applied without ultimate injury to the complexion.

ROUGH-CAST. In Architecture, the plastering of walls with mortar and fine gravel, left rough without any smoothing.

ROUGHING IN. *See* RENDERED AND SET.

ROUGH STUCCO. In Architecture, stucco floated and brushed in a small degree with water.

ROUND. The property of a circle, sphere, or right cylinder, and indeed of any solid of revolution, though most commonly confined to the sphere and cylinder.

ROU'NDEL. In Heraldry, an ordinary in the form of a circle. It is improper to say a roundel or, gules, &c., describing it by its tincture; unless, first, in case of counterchanges; secondly, where the roundel is of fur, or of equal tinctures, as a roundel ermine, a roundel checky of or and azure, &c.; otherwise, roundels have distinguishing names, according to their tinctures. A roundel or is called a *bezant*, from the gold coins of the Greek or Byzantine empire: a roundel argent, a *plate;* gules, a *torteau*, a kind of cake; azure, *hurt*, a species of flower; vert, *pomme;* sable, *pellet;* purpure, *golpe*. A field or charge, with equidistant roundels, is said to be *bezanty*, *platy*, &c., according to the tincture.

ROU'NDELAY, in Poetry, is properly a short poem of thirteen verses; eight in one rhyme, and five in another. *See* RONDEAU.

ROUND HEADS. A nickname given to the Puritans at the time of the civil wars by the Cavaliers, from the close black skull-cap, reaching down to the ears, which was then worn by staid and serious persons; or, more probably, from the custom that prevailed among them of wearing the hair closely cut to the head.

ROUND ROBIN. (Fr. rond ruban.) A phrase originally derived from a custom of the French officers, who, on signing a remonstrance to their superiors, wrote their names in a circular form, so that it might be impossible to ascertain who had headed the list. It is now used to signify any act by which a number of individuals bind themselves to pursue a certain line of conduct.

ROUND TABLE, KNIGHTS OF THE. The name given to the famous order of knights that existed in England under the reign of King Arthur, by whom it was founded. The members of this order are said to have been forty in number, and derived their name from a huge round marble table round which they were accustomed to sit. Their adventures form the themes of much of the early romantic poetry and ballads of England; and our own times have been peculiarly fertile in clearing away much of the obscurity in which the well-known names of Tristram, Lancelot, and other members of this order were enveloped. Sir W. Scott's labours in this field are too well known to require any remark. (See *Schlegel's History of Literature*, which gives a masterly sketch of the influence of the Round Table on the romantic poetry of that and succeeding ages.)

ROUP. A Scotticism for auction.

ROW. To propel a boat by oars. Rowing is reckoned the most favourable application of human strength; the whole force is, however, not effective on the oar, as the part inside the actual fulcrum, which is in the water, acts as a backwater. Some nations take short strokes, which they rise up in making; the English prefer a long stroke sitting, which, to say the least, saves much exertion. As the theory of rowing involves the resistance of fluids, it is necessarily defective.

ROYAL. In Naval affairs, the sail above the top-gallant sail. The term *royal* is also applied, in artillery, to a kind of small mortar.

ROY'ALISTS. The name applied originally to the adherents of the Bourbon family after the revolution of 1792; but now in common use to designate the party attached to the claimants of the Spanish and Portuguese thrones.

ROYAL OAK, *Robur Carolinum*. In Astronomy, a constellation formed by Halley in the southern hemisphere. *See* CONSTELLATION.

ROYALS. The name given by way of eminence to the *first* regiment of foot in the British service: it is supposed to be the oldest regular corps in Europe. (*James's Military Dict.*)

RUBEFA'CIENTS. (Lat. rubefacio, *I make red.*) Substances which, when applied to or rubbed upon the skin, induce a redness or blush upon the part, not followed by blister.

RU'BELLITE. Red schorl or tourmaline. There is a magnificent group of crystallized rubellite in the British Museum, from the cabinet of the late Mr. Greville.

RUBE'OLA. The measles. This disease is preceded by fever, with swelling and inflammation of the eyes; an oppressive cough; and about the fourth day there is an eruption of small red points, perceptible to the touch, which continues for four or five days, and then goes off with desquamation of the cuticle; but the fever, cough, soreness of the eyes, and irritable state of bowels are apt to continue for some time after the entire disappearance of the eruption. The most alarming cases are those in which the inflammatory symptoms and fever run very high, and which sometimes require bleeding, or blisters and cupping upon the chest; or in which there is a putrid tendency, with a dark livid colour.

RU'BEZAHL. The name of a famous spirit of the Riesengebirge in Germany, who is celebrated in innumerable sagas, ballads, and tales, and represented under the various forms of a miner, hunter, monk, dwarf, giant, &c. He is said to aid the poor and oppressed, and shows benighted wanderers their road; but wages incessant war with the proud and wicked. The origin of the name is obscure. (See the *Tales of Musæus.*)

RU'BICEL. A term applied to the Brazilian ruby.

RU'BRIC. (Lat. ruber, *red.*) In the language of the old copies of manuscripts, and of modern printers, any writing or printing in red ink. The date and place on a title page being frequently in red ink, the word *rubric* has come to signify the false name of a place on a title page. Many books printed at Paris bear the *rubric* of Genoa, London, &c. But the most common use of the word is in ecclesiastical matters. In MS. Missals, the directions prefixed to the several prayers and offices were written or printed in red ink; and hence, the *rubric* familiarly signifies the order of the liturgy, in Roman Catholic countries as well as in England.

RU'BY. A crystallized gem of various shades of red, found chiefly in the sand of rivers in Ceylon, Pegu, and Mysore. Among lapidaries, the scarlet-coloured is sometimes called *spinelle ruby;* the pale or rose red, *balass ruby;* and the yellowish red, *rubicelle.* It is inferior in value and beauty to the red sapphire, or oriental ruby of the jewellers. It consists of 83 alumina, 9 magnesia, and 7 or 8 chromic acid; the latter gives its colour.

RUDDER. A heavy flat piece or frame of wood, hung upon the stern post by means of pintles and gudgeons, for the purpose of steering the ship. The rudder is turned round the stern post as an axis, by the tiller, which enters the rudder head. In vessels drawing much water the rudder is deep and narrow; in flat-bottomed vessels, it is shallow and broad. When carried to a considerable breadth, as in the Chinese vessels it is pierced with holes, which preserves an increased leverage with a diminished direct resistance from the water.

When the rudder is broken off by the ship getting aground, or by a heavy sea, a temporary one is made by a topmast and other spars placed parallel, and loaded at the bottom with pigs and ballast, and confined to the stern post by hawsers leading on each side of the keel.

Rudder Coat. A covering of tarred canvass loosely put round the rudder head to keep the water from entering by the aperture, while it admits of the rudder being turned freely round.

Rudder Pendants. Strong pieces of rope ending in chains, by which the rudder, if unshipped, is held to the ship's quarter.

Rudder Shock. A piece of wood fitting between the head of the rudder and the rudder hole, to prevent the play of the rudder in case of the tiller being removed.

RUDE'NTURE. (Fr.) In Architecture, the rope or staff with which the lower parts of the flutings of columns are often filled. See Cabling.

RUDIA'RIUS. (Lat.) The term applied to a discharged gladiator. The word is derived from the staff (*rudis*), which was given him in token of his dismission.

RUDO'LPHINE TABLES. A set of astronomical tables computed by Kepler, and founded on the observations of Tycho Brahé. They were called the *Rudolphine Tables* in honour of Rudolph II., emperor of Bohemia, who, upon the death of Tycho in 1601, conferred upon Kepler the title of imperial mathematician, and undertook to defray the expenses of their preparation. Owing to various causes the work was not completed until 1627, when the tables were published at Ulm. They are the first that were ever calculated on the hypothesis that the planets move in elliptic orbits, and they contributed greatly to the progress of modern astronomy. For a detailed account of this very remarkable production, see Delambre, *Astronomie Moderne*, tom. i. p. 557.

RUFF. The name of the male of the *Machetes pugnax*, which is distinguished at the breeding season by a ruff or tuft of wide-spreading feathers, projecting behind the eyes and from the upper part of the neck. The female is called the *reeve*. See Machetes and Tringa.

RULE, in Arithmetic, denotes a certain prescribed series of numerical operations, adapted to discover from the given conditions to which an unknown number is subjected what that number is. They are generally distinguished by particular names, according to the purposes for which they are given, or the particular nature of the business for which they are required; as the rules of interest, the rules of fellowship, &c.

Rule. In a monastic sense, a system of laws or regulations by which monasteries and other religious houses are governed, and which the monks, nuns, and novices vow at their entrance to observe. See Orders, Monastic.

Rule. In Law, an order of one of the three superior courts of common law. Rules are either general or particular; the former being such orders relating to matters of practice as are laid down and promulgated by the court for the general guidance of the suitors: the latter are such orders as are confined to the particular case in reference to which they have been granted. See Courts of Law, and Pleading.

RULE OF THREE, in Arithmetic, is the rule by which when three numbers are given a fourth is to be found, so that the four shall be in direct or inverse proportion, as the case may require.

RULES. In the Fine Arts, those laws and maxims founded on the general and fundamental truths of nature by which artists are guided in their compositions.

RULES, BRASS. Pieces of brass of different thicknesses made letter high, to print with. They are made in lengths of fourteen inches, but of late years lengths half as long again have been made. One of the edges is bevelled so as to print a fine line, and when a thicker line is required the bottom edge is placed uppermost, which is the full thickness of the brass; by this means lines of different thicknesses are obtained, and also double lines, a thick one and a fine one, when required. They are used for column lines in table work; to separate matter that requires to be distinct; and to be placed round pages.

In cases where diagrams are required, and there is no engraver within reach, they may be formed by a clever workman with brass rule. Of late years many ingenious and elaborate imitations of architectural drawings of buildings, with pillars, &c. have been made with brass rule; and in this department of art Mr. Ebenezer Parkes, of Fetter Lane, has displayed great skill and ingenuity.

RULE, CARPENTER'S. A folding ruler, generally used by carpenters and other artificers, having a variety of scales adapted to facilitate the calculations of most frequent occurrence by inspection. Sometimes it has a sliding piece in one of its legs, by which its use is greatly extended. See Sliding Rule.

RULE, GAUGING, is a rule adapted in the same manner to discover the contents of casks and other vessels. It is used by the officers of excise in surveying the articles in the process of manufacture that are liable to duties. See Gauging.

RUM. A spirituous liquor distilled from the fermented juice of the sugar cane, or from molasses. Its flavour is due to the presence of a peculiar volatile oil: its average proportion of alcohol fluctuates between 50 and 56 per cent. The rum consumed in the United Kingdom is entirely the produce of the West Indies, and to a great extent of Jamaica; and for this preference it is indebted partly to its superior quality, and partly to its being protected against rum of East India produce by a differential duty of 6*s*. per gallon; the duty on West India rum being 9*s*., that on East India rum being 15*s*. per gallon. The quantity of rum entered for home consumption for the years 1839-40, averaged 2,670,515½ gallons; the duty on it for the three years, 1837-38-39, averaged 1,372,540*l*.; and in 1840, the gross amount was 1,154,544*l*. The consumption of rum in this country has long been gradually declining.

RU'MEN. (Lat.) The name of the paunch or first cavity of the complex stomach of the Ruminant quadrupeds.

RU'MINANTS, *Ruminantia*. (Lat. rumino, *I chew the cud.*) The name given by Cuvier to the *Pecora* of Linnæus, an order of Ungulate Mammals, including those which have a complicated stomach of four cavities so disposed as to allow of rumination, and a cloven hoof.

RUMINA'TION. (Lat. rumino.) The act by which food once chewed and swallowed is a second time subjected to mastication. Digestion is always preceded by this action in the order of Mammals, hence called "Ruminants;" but very rarely, and as an exceptional case, in any other animal. The stomach of the Ruminants is specially organized for rumination, consisting of four distinct cavities, all of which communicate with a muscular canal at the termination of the œsophagus. Hard, solid, or coarsely masticated food, passes from the beginning of the muscular canal into the first cavity of the stomach, called the *rumen*, or paunch. Water is received into the second cavity, called the *reticulum*, and almost exclusively occupies the honeycomb cells of that cavity; it is gradually mixed with the coarsely divided food which is undergoing mastication in the rumen. When this is sufficiently advanced, a portion of the mass is received into the muscular canal at the termination of the œsophagus; it is there moulded into a ball, and propelled by a rapid and inverted action of the muscles of the gullet into the mouth, where it is more perfectly masticated, mixed with fluid, and again swallowed. It now passes directly into the third stomach, called the *psalterium*, from the broad leaf-like plates of membrane with which it is occupied; here the superfluous fluid, which otherwise might have too much diluted the gastric juice, is absorbed, and the subdivided cud passes gradually into the fourth or true digesting stomach, called the *abomasus*. In the camel tribe, water-cells are developed at the sides of the rumen, in addition to those of the reticulum, and the psalterium is not separated by any contraction from the abomasus.

RUMP PARLIAMENT. In English History, after the dissolution of Richard Cromwell's parliament, and his own demission of the protectorate, a council of officers, at whose head were Desborough, Lambert, and others, having seized the supreme authority, found it advisable to call together the remnant of the Long Parliament, which had been forcibly dissolved by Oliver. It

was assembled in May, 1659; and consisted of little more than seventy members, those who had been excluded not being allowed to resume their seats. This body soon became odious to the Presbyterian and Royalist parts of the nation, and by its own assumption of power displeased the officers who had called it again into being. It acted, however, with some vigour and determination, and defeated a variety of royalist conspiracies; but having ventured so far as to cashier Lambert and others of the leading officers, the troops again surrounded Westminster Hall, and expelled it, on the 13th October in the same year. But Fleetwood, who had the command of the army, being unable to keep together the distracted government, the officers once more invited the parliament to sit again, which it did on the 26th of December. It once more assumed absolute authority; but General Monk took part against it. On his invitation a good many of the excluded members went to the house (Feb. 21.), and thus placed the Independents, who had hitherto ruled it, in a minority; and having passed some measures reversing its former acts, the parliament dissolved itself. It got its nickname from being, as it were, the remnant and fag-end of the old Long Parliament, and was treated by the nation with general contumely and derision. But it cannot be denied that, utterly unable as it was to command the divided nation, it showed boldness and vigour in its conduct, which, with a little more popularity, would probably have ensured great successes. Vane and Hazlerig were its leading members.

RU'NCINATE. In Botany, hooked back, or curved in a direction from the apex to the base; as the lobes of the leaf of the dandelion.

RUNES (Germ. Runen), are properly the signs or letters of the ancient alphabet peculiar to the northern nations (Germans and Scandinavians). Schlegel deduces this alphabet from the Phœnicians. (*Lectures on Ancient and Modern Literature.*) Others have supposed it to have been derived from that of the Romans; but its originally consisting only of sixteen letters has been urged as an argument against this hypothesis. The runen inscriptions found in Germany (especially Northern Saxony) are thought by some to have tokens of an origin somewhat different from the Scandinavian. (*Grimm on the German Runes*, 1821.) The antiquity of both has been much disputed. Of those found in Gothland, it is said that the oldest are not earlier than A. D. 1200, the latest 1449: 1300 stones with Runic inscriptions have, it is said, been discovered in Sweden; many in Denmark; none in Lapland or Finland. Runic staves are massive sticks, generally of willow, inscribed with Runic characters, probably of magical import. (See *Conv. Lexicon.*)

RUPEE. A coin of different values, current in different parts of the East Indies. *See* MONEY.

RU'PIA. (Gr. ῥυπος.) An eruption of flattish vesicles, succeeded by an ill-conditioned discharge, which concretes into thin scabs easily rubbed off and regenerated; they generally occur as a consequence of poor diet and weak habit of body. Light nutritious food, tonics, and alteratives are the remedies.

RUPTURE. *See* HERNIA.

RU'RAL ECO'NOMY. The general management of territorial property, either by the proprietor or his agent. On a small scale, the agent is termed a bailiff or farm servant; and on a large scale, a land steward or factor. The duties of the latter are to collect the rents, and see that the different clauses in the leases by which the tenants hold their lands are fulfilled; and of the former, to cultivate the land in such a manner as to produce the greatest profit, or to fulfil the intentions of the proprietor as to the kind of produce which he considers it desirable to obtain. *See* AGRICULTURE.

RUST, in its ordinary acceptation, is the reddish peroxide which is found on the surface of iron when exposed to moisture.

RUST. In Horticulture. *See* MILDEW.

RU'STIC. (Lat. rus.) In Architecture, a term applied to work jagged out into an irregular surface. Work also which is left rough, without tooling.

RUTA'CEÆ. (Ruta, one of the genera.) A natural order of plants, composed principally of trees and shrubs inhabiting the warmer parts of the world, seldom of herbaceous plants. The species are sometimes very ornamental, especially those belonging to the genera *Correa*, *Boronia*, and *Diosma*. Some, as the common rue, the bucku plant, &c., are remarkable for having a powerful, peculiar, unpleasant odour, and antispasmodic quality; and a few have a febrifugal bark. The *Dictamnus albus*, or *Fraxinella*, is extremely fragrant, and gives off an inflammable vapour.

RUTIDO'SIS. (Gr. ῥυτις, *a furrow.*) A disease of the eye, in which the cornea appears shrunk and puckered. It is produced by a wound, or by a deficiency of the aqueous humour, which happens from old age or fevers, or occasionally from the action of an extremely arid atmosphere. After death it is produced by the evaporation of the aqueous humour through the cornea, and the consequent shrinking of that membrane.

RU'TILITE. (Lat. rutilus, *red.*) Native oxide of titanium.

RYA'COLITE. (Gr. ῥυαξ, *a stream*, and λιθος, *a stone.*) A name given to glassy felspar.

RYE (Ger. *roggen;* Du. *rog, rogge*), according to some, is a native of Crete; but it is very doubtful if it be found wild in any country. It has been cultivated from time immemorial, and is considered as coming nearer in its properties to wheat than any other grain. It is more common than wheat in many parts of the Continent; being a more certain crop, and requiring less culture and manure. It is the bread corn of Germany and Russia. In Britain it is now very little grown, being no longer a bread corn; and therefore of less value to the farmer than barley, oats, or peas.

RYOTS. (Arab. *a subject.*) The name given to the cultivators of the soil in Hindostan. Their social condition presents many singular and interesting features, to some of which we shall here advert. In all eastern countries the rulers may be said to be the proprietors of the soil; but in India the *cultivators* have a perpetual, hereditary, and transferable right of occupancy, so long as they continue to pay the share of the produce of the land demanded by the government. The value of this right of occupancy to the rural population depends on the degree of resistance which they have been able to oppose to the exactions of arbitrary governments. In Bengal and the adjacent provinces of India, from the peculiarly timid character of the inhabitants, and the open and exposed nature of the country, this resistance has been trifling indeed; and consequently the value of the right of occupancy in the peasant, or ryot, has been proportionally reduced. This, also, may be considered, though with some modifications, as being nearly the condition, in this respect, of the inhabitants of every part of the great plain of the Ganges, comprising more than half the population of Hindostan. But where the country is naturally difficult, the people have been able more effectually to resist the encroachments of the head landlord, or state, and to retain a valuable share in the property of the soil. This has been particularly the case along the ghauts, as in Bednore, Canara, Malabar, &c.; the inhabitants of which provinces not only lay claim to a right of private property in the soil, but have been generally ready to support their claim by force of arms. There can be no question, indeed, that the same modified right of property formerly existed every where; and it is indeed impossible that otherwise the land should ever have been reclaimed from the wilderness. But in those parts of India which could be readily overrun by a military force, the right of property in the soil has long been little else than the right to cultivate one's paternal acres for behoof of others, the cultivators reserving only a bare subsistence for themselves.

Under the Mogul emperors, the practice in Bengal was to divide the gross produce of the soil, on the *métayer* principle, into equal shares; whereof one was retained by the cultivator, the other going to government as rent or tax. The officers employed to collect this revenue were called *zemindars;* and in the course of time their office seems to have become hereditary. It may be remarked that, in Persian, zemindar and landholder are synonymous; and this etymology, coupled with the hereditary nature of their office, which brought them exclusively into contact with the ryot or occupier, as well as with the government, led many to believe that the zemindars were in reality the owners of the land, and that the ryots were their tenants. This, however, it is now admitted on all hands, was an incorrect opinion. The zemindars in reality were tax-gatherers, and were, in fact, obliged to pay to the government *nine tenths* of the produce collected from the ryots, retaining only one tenth as a compensation for their trouble; and, so long as the ryots paid their fixed contribution, they could not be ousted from their possessions, nor be in anywise interfered with.

But notwithstanding what has now been stated, the perpetual or zemindary settlement, established by Lord Cornwallis in Bengal, in 1793, was made on the assumption that the zemindars were the proprietors of the soil. His lordship, indeed, was far from being personally satisfied that such was really the case; but he was anxious to create a class of large proprietors, and to give them an interest in the improvement and prosperity of the country. It is clear, however, that this wish could not be realized without destroying the permanent rights of the ryots; for, unless this were accomplished, the zemindars could not interfere in the management of their estates. The interests of the zemindars, and the rights of the ryots, were plainly irreconcileable; and it was obvious that the former would endeavour to reduce the latter to the condition of tenants at will. But this necessary consequence was either overlooked or ineffectually provided against. The zemindars became, under condition of their paying the assessment or quit-rent due to government, proprietors or owners of the land. The amount of the assessment was fixed at the average

of what it had been for a few years previously, and it was declared to be perpetual and invariable at that amount. When a zemindar fell into arrear with government, his estate might be either sold or resumed.

That the assessment was at the outset, and still is too high, cannot well be doubted; and it must ever be matter of regret that the settlement was not made with the ryots, or cultivators, rather than with the zemindars; but, notwithstanding these and other defects, the measure was, on the whole, a great boon to India. Until the introduction of the perpetual system into Bengal, the revenue was raised in it, as it continues to be in the rest of India down to the present day, by a variable as well as a most oppressive land-tax. We all know what a pernicious influence tithe has had in this country; but suppose that, instead of amounting to 10, tithe had amounted to 50 per cent. of the gross produce of the soil, it would have been an effectual obstacle to all improvement; and the country would now have been in about the same state as in the days of Alfred, or of William the Conqueror.

In France, Italy, and other parts of Europe, where the *métayer* system is introduced, the landlord seldom or never gets half the produce, unless he also furnish the stock and farming capital, and, in most cases, the seed. But in India neither the government nor the zemindars do any thing of the sort: they merely supply the land, which is usually divided into very small portions, mostly about six, and rarely amounting to twenty-four acres. A demand on the occupiers of such patches for half the produce is quite extravagant; and hence the excessive poverty of the people, which is such as to stagger belief. Still, however, the perpetual system is vastly preferable in principle, and also in its practical influence, to any other revenue system hitherto established in India. It set limits to fiscal rapacity, and established, as it were, a rampart beyond which no tax-gatherer dared to intrude. The enormous amount of the assessment, and the rigour with which payment was at first enforced, ruined an immense number of zemindars. But their lands having come into new and more efficient hands, a better system of management was introduced, and the limitation of the government demand gave a stimulus to improvement unknown in any other part of Hindostan. This, in fact, was the grand desideratum. A land-tax, that may be increased should the land be improved, is all but certain to prevent any such improvement being made. This has been its uniform operation in every country in the world that has had the bad fortune to be cursed with such a destructive impost. But a heavy land-tax, provided it be fixed and unsusceptible of increase, is no bar to improvements, unless in so far as it tends to deprive the proprietors and occupiers of land of the means of making them. There is, in such a case, no want of security; and the cultivator is not deterred from attempting improvements, or of bringing superior enterprise and industry to operate on his estate, by the fear that the tax will, in consequence, be increased.

The truth of what is now stated has been fully evinced in Bengal during the last twenty or thirty years; for both the population and the land revenue of that part of our Indian empire have greatly increased. A great deal of waste land has been cultivated, and various works have been undertaken that would not be so much as dreamed of in any other part of our empire in the East. But, with all this, there has been but little, if any, improvement in the condition of the people of Bengal under our government. They, in fact, are practically excluded from at least all direct participation in the benefits resulting from the limitation of the assessment. They have merely exchanged one taskmaster for another. It is their landlords who have been the great gainers. The occupiers still, generally speaking, hold under the *métayer* principle, paying half or even more of their produce as rent; so that their poverty is often extreme, and their condition not infrequently inferior even to that of the hired labourer, who receives the miserable pittance of two annas, or about 3*d*. a day as wages.

It seems, however, as if there were some strange fatality attending the government of India: and that the greatest talents and the best intentions should, when applied to legislate for that country, produce only the most pernicious projects. The perpetual settlement carried into effect by Lord Cornwallis in Bengal was keenly opposed by Lord Teignmouth, Colonel Wilkes, Mr. Thackeray, Sir T. Monro, and others, whose opinions on such subjects are certainly entitled to very great respect; and it would seem that the Board of Control became, at length, favourable to their views. In consequence of this change of opinion it was resolved to introduce a different system, under the superintendence of its zealous advocate, Sir Thomas Monro, into the presidency of Madras, or Fort St. George. This new system has received the name of the *ryotwar* settlement. It proceeds on the assumption that government possesses the entire property of the soil, and may dispose of it at pleasure: no middlemen or zemindars are interposed between the sovereign and the cultivators; the ryots being brought into immediate contact with the collectors appointed by government to receive their rents. It is impossible for us to enter into the details of this system, which are complicated in the highest degree; but we beg to refer the reader for full information to the *Geog. Dict.*, art. "India, British."

RY'TINA. (Gr. ῥυτις, *a furrow*.) The name of a genus of herbivorous Cetaceans, of which a species inhabiting the coasts of Kamschatska (*Rytina stelleri*), with a wrinkled and furrowed integument, is the type.

S.

S. A sibilant articulation, found in all the languages of which we have any knowledge. S may be regarded as a species of semivowel, from its forming a kind of imperfect sound without the aid of any of the vowels; and from its peculiar quality of being able to be sounded before all the consonants, it has been termed by grammarians *suæ potestatis litera*. It is susceptible of numerous interchanges, both in the ancient and modern languages. As an abbreviation, S is used for *socius*, *societas*, *south*, *solo*, &c.

SA'BAISM, or SABÆISM. (From the Heb. zaba, *lord*; whence Sabaoth, &c., or *army*, *the host of heaven*.) The religion which has for its objects of worship the sun, moon, and other heavenly bodies. This belief prevailed in very remote ages in the Asiatic countries between the Euphrates and the Mediterranean; and Chaldæa, the native land of astronomy, was its most celebrated seat. Many allusions are made to this species of worship in the Old Testament, especially in the invectives of the prophets against the various forms of idolatry borrowed by the Jews from their heathen neighbours. (See *Sale's Preliminary Discourse to the Koran*.) There is a valuble memoir on the Sabaism of the ancient Persians by Foucher, *Mem. de l'Ac. des Inscr.* vol. xxv. p. 160. See also *Russell's Connexion of Sacred and Profane History*, vol. i.

SABA'OTH. A Hebrew word, signifying hosts or armies. It occurs in the New Testament as a designation of the Almighty (the Lord of Sabaoth).

SABA'SIA. In ancient Mythology, festivals in honour of various divinities, entitled Sabasii: the origin of which term is not clear. Mithras, the sun, is called Sabasius in ancient monuments, whence the word seems to have some connection with the root of Sabäism (see above); but Bacchus was also thus denominated, according to some, from the Sabæ, a people of Thrace: and the nocturnal Sabasia were celebrated in his name. Jupiter *Sabasius* is thought to be the same as *Ægiochus*; the Phœnician word tsebaoth signifying kids, as the Greek αἰξ a goat. But there is, probably, some more general oriental meaning, which has not yet been reached.

SABBATA'RIANS. In Ecclesiastical History, various sects have been so called; particularly a subdivision of the Anabaptists in the 16th century, who observed the Jewish sabbath. The *Sabbatians* of the 4th century were followers of Sabbatius, a Novatian bishop, who attempted to introduce some Jewish observance into the church. They are said to have had the singular peculiarity of abhorring the use of the *right* hand; whence they were called Αριστεροι, or left-handed.

SA'BBATH. A Hebrew word signifying *rest*, applied by the Jews to the seventh day of their week (our Saturday), on which they were commanded to abstain from all manner of work, because "in six days God created the heavens and the earth, and rested the seventh day." The universal practice of the Christian church from the earliest period, in conformity to what may be gathered from some passages in the Acts of the Apostles, has set apart the first day of the week (Sunday) for the especial worship of God, in memory of the resurrection of our Lord on that day. The obligation upon which the observance of Sunday rests has been placed upon different grounds. The most prevalent opinion supposes the commandment given to the Jews originally to be of universal obligation, as far as the observance of one day in seven. But there have been many divines in all ages who have held that all the formal obligations of Judaism, as well those of the commandments as those of the Levitical law, were abrogated on the advent of our Saviour, and consider the consent of the church and the practice of the Apostles to be the only sufficient authority for this observance. It is upon this principle that the Continental churches hold themselves justified in indulging in all sorts of worldly recreation on Sundays, after the services of public worship are concluded. Archbishop Whately has recently drawn attention to the subject by his able arguments against the popular opinions on which the observance of the Sabbath is made to rest.

The name *Sabbatarians* was given to some early sects of Judaising Christians, who insisted on the observance of the Sabbath (Saturday) under the new dispensation.

SABBA'TICAL YEAR. Every seventh year among the Jews was so called, because on that year the land was allowed to lie fallow, and the people were supported by the tripled produce of the year preceding. (Exod. xxiii. 10. Levit. xxv. 3. 20.)

SABE'LLIANS. Heretics of the 3d century, followers of Sabellius, whose system was an attempt to explain the doctrine of the Trinity by representing the Father as the sole person, and the Son and Spirit as attributes, or emanations from him. Thus they compared the Divinity to the sun; of which the Father would be analogous to the substance, the Son to the light, and the Holy Ghost to the heat. This scheme has been known in later times as that of the Modal Trinity; and some divines of the orthodox English church have found themselves entangled in it, when attempting to explain accurately the mysterious doctrine to which it refers. On the other hand, their opponents have been led, inadvertently in some cases, to make too formal a distinction of the Three Persons, and have thereby subjected themselves to the charge of Tritheism. (See *Mosheim*, transl. ed. 1790, vol. i. p. 305.)

SA'BIANS. A Christian sect, also called Christians of Saint John; thought by some to be the remnant of the Jewish Hemerobaptists found in Persia and Arabia, principally at Basra. (See *Mem. de l'Ac. des Inscr.* vol. xii.; and *Mosheim*, vol. iv.)

SA'BLE. A small quadruped, allied to the martin-cat, celebrated for the fine quality and rich colour of its fur, of which the hairs turn with equal ease in every direction. A single skin of the darker colour, though not above four inches broad, has been valued as high as 15*l*. The sable (*Mustela zibellina*, Linn.) is principally a native of the northern regions of Asia: it is hunted and killed for the Russian market, either by a single ball, a blunt arrow, or traps, by exiles or soldiers sent for that purpose in the deserts of Siberia. The skin is in the highest perfection from November to February. A nearly allied animal, called the "fisher," inhabits North America, and is similarly sought after and destroyed for its fur.

SABLE. In Heraldry, black: derived, probably, from the fur of the animal sable. One of the colours, or tinctures, employed in blazonry. It is equivalent to diamond among precious stones, Saturn among planets. In engraving, it is represented by vertical and horizontal lines crossing each other.

SACCHA'RIC ACID. (Lat. saccharum, *sugar*.) An uncrystallizable acid product, formed along with oxalic acid during the action of nitric acid on sugar.

SA'CCHAROID. (Lat. saccharum, and Gr. εἶδος, *form*.) A texture resembling that of loaf sugar; as saccharoid carbonate of lime, &c.

SACCHARO'METER. (Lat. saccharum, and Gr. μέτρον, *a measure*.) An instrument for determining the specific gravity of brewers' and distillers' worts.

SA'CCHARUM. *See* SUGAR.

SACCHOLA'CTIC ACID. (Lat. saccharum, and lac, *milk*.) An acid obtained by digesting sugar of milk in nitric acid. It is identical with that obtained from gum, and termed *mucous acid*.

SA'CER MO'RBUS. (Lat. *sacred disease*.) One of the names applied by the older writers to epilepsy, though other disorders were also occasionally similarly designated.

SACK. (Fr. *vin sec*, from which the term is generally supposed to be derived.) A Spanish wine of the dry kind. The important part which it plays in Shakspeare is well known. Falstaff calls it *sherris sack*, which means sherry sack; so called, says Blount, in his *Glossographia*, from Xeres, a sea town of Corduba, where that kind of sack is made. At a later period, sack seems to have been used as a general term for all kinds of sweet wines; and it has been conjectured that, instead of being a corruption of the French *sec*, as above noticed, it derives its name more probably from a common practice of the Spaniards, of putting their sweet wines into *sacks* made of goat skins, and thus transporting them from one place to another.

It may be interesting to observe, that the term *sack*, in the sense of a *bag*, is found in all the European and many Asiatic languages.

SA'CKBUT. A wind instrument of the trumpet species, but differing from the common trumpet in form and size. It is of low or bass pitch, and is drawn out or shortened by the means of sliders, according to the acuteness or gravity of the tone to be produced. It is, in fact, the trombone of the Italians.

SA'CRAMENT. (Lat. *an oath*.) The military oath taken by every Roman soldier, by which he swore to obey his commander and not desert his standard.

SACRAMENT. In Theology, a word which does not occur in scripture, nor possesses any exact equivalent there; but employed very early by writers in theology to signify certain distinctive ceremonies of the Christian faith. Our Saviour appointed the baptism of believers as an initiatory rite; he also commanded the observance of the supper of the Lord to be held in remembrance of him. These, then, are the badges by which Christian men are known, and by which they make profession of their belief. The expressions of scripture, moreover, with which the appointment of these ceremonies is attended, have been generally considered to attach some ulterior meaning to them. The one is called the second birth, the other is said to be the communion of the body and blood of our Saviour Christ; and the mysteries which seem to be concealed under these terms have been made the subjects of various interpretations. According to the general consent of ancient orthodoxy, the sacraments have in themselves a peculiar efficacy, conferring grace upon the recipient, and imparting to him the benefits of the Christian covenant. The Romish church is accused of holding the extreme opinion that this grace is conferred *ex opere operato*, by the mere act, the recipient remaining passive; that they fail of operation only where he is under the influence of positive sin; but that the administration of the Eucharist to a dying man unconscious of the whole proceeding, would have the same effect as if he received it in the most holy frame of mind. The English church requires the worthy acceptation of the person himself, as is expressly stated, with a tacit reference to this superstitious notion, in its twenty-fifth article. It guards, at the same time, against the idea very generally held among the Protestant churches abroad, and our own dissenting sects, in the words with which the article begins:—"Sacraments ordained of Christ be not only *signs* or *tokens of Christian* men's profession; but rather they be certain sure witnesses and effectual signs of grace, and God's will towards us, by the which he doth work invisibly in us, and doth not only quicken, but also strengthen and confirm our faith in him."

The question as to the number of such ceremonies must be settled by the definitions of a sacrament which theologians shall propound. It is agreed that a sacrament is a federal rite, instituted by Christ or the Apostles, with a direct appointment of *matter* by which some interior meaning is signified, and the *form* of manner of its application. This definition is conceived by Protestants to restrict the number to two only: the Romanists extend it to seven, adding to Baptism and the Lord's Supper Confirmation, Penance, Orders, Matrimony, and Extreme Unction.

SA'CRED WAR. The most remarkable known by this name in classical history is that which commenced with the seizure of Delphi by the Phocians, B. C. 357, and was ended by the conquest of the Phocians by Philip of Macedon, B. C. 346, according to the chronology of Clinton. (*Fasti Hellenici*.)

SA'CRIFICE. Generally any offering made to the Deity; but more properly that of a victim upon an altar, accompanied by customary ceremonies and forms of prayer, with the idea of gratifying God and averting his displeasure. In the scriptures we meet with offerings, both of fruits and of animals, antecedent to any command or institution of God; such as those of Cain and Abel, of Noah and the Patriarchs: many of which, nevertheless, are described as acceptable to him. In the Levitical Law, however, sacrifices are ordained by divine appointment; and a question arises as to the probability of a similar command having been in fact given to our first parents. The universality of the practice undoubtedly requires either the supposition of an original revelation, or the discovery of a common principle impelling all men alike to the adoption of what at first sight seems to militate against our ideas of reason, and the absurdity of which has, we know, been represented in the strongest light by the sages of all nations at a certain period of the intellectual development of each. Those divines who consider the appointment to have emanated directly from God conceive it to have been, from the first, typical of the last and greatest sacrifice,—that of our Saviour on the cross. It may fairly be asked of those who look for logical reasons for all divine appointments, whether, upon human principles, it seems the more probable that the sacrifice of Christ being predetermined, the notion should be familiarized to mankind by ordaining a previous practice; or that, the practice existing and having a meaning of its own in all minds, the new revelation should be accommodated to our notions by adopting that very practice for its foundation? If, on the other hand, we follow the general current of modern opinion upon this subject, and inquire for some general principle of our nature to account for the universal reception of the ideas, we may discover it perhaps in the perpetual sense of obligation with which the enjoyment of prosperity is properly accompanied, and which in some minds takes the form of grateful acknowledgment, and the devotion to the giver of some portion of the gifts by which we are ourselves gratified; and in others becomes an uneasy scruple, and suggests the voluntary surrender of a part with a view to the more secure enjoyment of the remainder.

SA'CRILEGE. (Lat. sacrilegium.) The profanation of any thing or place consecrated to the service of God.

SA'CRISTY. (Lat. sacer, *sacred*.) In Architecture,

an apartment attached to a church, in which the consecrated vessels of the church, and the garments in which the clergyman officiates, &c., are deposited.

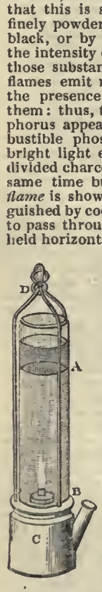
SA'CRUM. The posterior bone of the pelvis, articulated to the last lumbar vertebra, and firmly united on each side to the hip bones; below, the *os coccygis* is attached to it. It probably derives its name from having been offered by the ancients in sacrifices. In young subjects it is composed of five or six pieces united by cartilages, but in more advanced age it becomes one bone.

SADDER. A work in the modern Persian tongue, comprising a summary of various parts of the *Zendavesta*, or sacred books of the ancient Persians (which see). The authority and character of the Sadder are supposed to be very small: some attribute it to the Parsees, and give it an antiquity of several centuries; others consider it a more modern forgery. (See *Mem. de l'Ac. des Inscr.* vol. xxxviii.)

SA'DDLE. In Sea Language, a lump of wood acting as a seat or rest to the heel of a boom, and shaped accordingly.

SA'DDUCEES. A peculiar sect of religionists among the Jews. It is remarked that during the time that prophets are recorded to have arisen among the Jews, there is no account of the existence of any sects among them: they frequently fell away into total idolatry; but whenever recalled from that corruption, they appear to have reverted in a body to the pure religion of their ancestors, and never to have been separated in religious distinctions among themselves. The most ancient sect was that of the Sadducees, whose founder, Sadok, lived about 250 years B.C. He appears to have restricted the providence of God to the distribution of the temporal rewards and punishments which form the main feature of the old dispensation. In the time of our Saviour his followers entirely rejected the doctrine of a resurrection. They were assimilated also to the Epicureans in maintaining the perfect freedom of human actions; and like those pagan philosophers were few in number, and only of the highest and most literary classes. They were distinguished also from the Pharisees by the rejection of traditions, and by strict adherence to the written law alone. (See *Milman's Hist. of Christianity*, vol. i. p. 75. 211.)

SA'FETY LAMP. A lamp invented by Sir H. Davy, which is so constructed as to burn without danger in an explosive atmosphere. Flame may be considered as vapour or aëriform matter in a state of intense ignition; the temperature, therefore, of flame is always very high. It is, however, independent of its luminosity; for some of the dimmest flames, those of pure hydrogen gas, and of alcohol, for instance, are those which are hottest; and that this is so may be shown by projecting into them finely powdered substances, such as magnesia or lamp black, or by holding in them fine platinum wire, when the intensity of their temperature is rendered evident by those substances becoming white hot. And whenever flames emit much light they derive that property from the presence of finely divided matter diffused through them: thus, the intense brilliancy of the flame of phosphorus appears to depend upon the particles of incombustible phosphoric acid diffused through it; and the bright light emitted by a gas flame depends upon finely divided charcoal, which is ignited by the gas and at the same time burned. The correctness of this *theory of flame* is shown by the circumstance of its being extinguished by cooling; and this is best effected by causing it to pass through a piece of fine wire gauze, which, when held horizontally in the midst of the flame, extinguishes its upper part: the inflammable vapour or gas, and the soot or carbon, pass through, but in passing are so far cooled as to be extinguished; they may, however, be rekindled by applying a flame above the wire gauze. That the wire gauze merely acts by its cooling power, is shown by the flame passing through it when it acquires a white heat, or when its meshes are not fine enough to exert a due cooling power; it is also found that very hot flames, such as that of hydrogen, will pass through tissues which are impervious to flames of a lower temperature, such as that of a common candle or a gas flame. (*See* FLAME.) The application of these principles to the construction of the safety lamp is as follows:— The flame of a small oil lamp C is surrounded by a cylinder of wire gauze A B (doubled at A, where likely to become hottest, and protected by the stout wire frame D), and burns within it, the air having free ingress and egress. When it is immersed in an explosive atmosphere, such as that of a coal mine infested by fire damp, the inflammable gas enters from without and burns *in* the cage; but, in consequence of the cooling power of the wire gauze, no flame can pass *outwards* so as to ignite the surrounding atmosphere: the miner, therefore, is warned of his danger by the appearance of the lamp. As long as the external atmosphere is safe, the lamp burns as usual; but upon the approach of the fire damp the flame is more or less enlarged; and in the most explosive condition of the surrounding air the cylinder appears filled with a blue lambent flame, which flickers within it, the wick of the lamp appearing for the time extinguished. It is, however, rekindled as the air becomes more pure; or should the fire damp greatly predominate, it may be entirely extinguished. Before this happens, however, the miner is duly apprised of his danger, and has time to retreat. (See *Davy on the Safety Lamp.*)



SAFETY VALVE. *See* STEAM ENGINE.

SA'FFLOWER. The dried flowers of the *Carthamus tinctorius*, or bastard saffron, used as a dye stuff, and in the preparation of the pigment called *rouge*.

SA'FFRON. The prepared stigmata of the *Crocus sativus*. The stigmata of this purple crocus are of a deep orange colour, and when in quantity have a peculiar and very characteristic odour; they are used in medicine, chiefly as a rich yellow or orange colouring matter. Saffron is now chiefly imported from the south of Europe, especially Spain; it was formerly largely cultivated in this country in the vicinity of Saffron Walden in Cambridgeshire. Saffron is often largely adulterated with the petals of other plants, especially with those of the marigold.

SA'GA. The general name of those ancient compositions which comprise at once the history and mythology of the northern European races. Their language is different from the modern Danish, Swedish, and Norwegian, and is more powerful and expressive than either of these later dialects. Of the mythological sagas the most famous are the saga of Regnar, Lodbrok, the Hervarar saga, the Voluspa saga, and the Wilkina saga. The historical are very numerous; the Jomsvikingia saga and the Kaflinga saga comprehend much of the early annals of Norway and Denmark; the Eyrbiggia saga is the chief historical document of ancient Iceland. It is, however, to be remembered, that the chief object of the relators is the interest of the narrative; so that as mere histories they are of imperfect value. Many of them are collected in the great work of Snorre Sturleson called *Heimskringla*. The most classical period of these compositions is considered by antiquaries to fall within the 12th and 13th centuries.

SAGA'PENUM. A fetid gum-resin brought from Persia and Alexandria, probably the produce of a species of *ferula*. It is occasionally used in medicine as a nervine and stimulating expectorant. Its odour somewhat resembles that of assafœtida, but it is much weaker.

SA'GGER. A clay used in making the pots in which earthenware is baked, and which are called *saggers* or *seggers*.

SAGGING TO LEEWARD. A Nautical term, denoting the movement by which a ship makes considerable lee-way.

SAGI'TTA. (Lat. *arrow*, or *dart.*) One of Ptolemy's 48 constellations in the northern hemisphere. *See* CONSTELLATION.

SAGI'TTA. A term used by the older writers on trigonometry to denote the *versed sine* of an arc; from its resemblance to an arrow standing on the chord of the double arc.

SAGITTA'RIUS. (Lat. *the Archer.*) One of the twelve constellations of the zodiac. It is represented on celestial globes and charts by the figure of a centaur in the act of shooting an arrow from his bow.

SAGI'TTATE. (Lat. sagitta, *an arrow.*) In Zoology, a part of an animal is so called when it is triangular and hollowed out at the base, with posterior angles.

SA'GO. A species of fecula or starch obtained from the cellular substance of an East Indian palm tree, the *Sagus farinifera*. It is usually granulated, and known in the trade under the name of *pearl sago*.

The tree, when at maturity, is about 30 feet high, and from 18 to 22 inches in diameter. Before the formation of the fruit, the stem consists of an external wall about 2 inches thick, the whole interior being filled up with a sort of spongy medullary matter. When the tree attains to maturity, and the fruit is formed, the stem is quite hollow. Being cut down at a proper period, the medullary part is extracted from the trunk, and reduced to a powder like sawdust. The filaments are next separated by washing. The meal is then laid to dry; and being made into cakes is baked and eaten. For exportation, the finest sago meal is mixed with water, and the paste rubbed into small grains of the size and form of coriander seeds. This is the species principally brought to England, for which market it should be chosen of a reddish hue, and readily dissolving in hot water into a fine jelly. Within these few years, however, a process has been invented by the Chinese for refining sago, so as to give it a fine pearly lustre; and the sago so cured is in the highest estimation in all the European markets. It is a light, wholesome, nutritious food. It is sent from the islands where it is grown to Singapore, where it is granulated and bleached by the Chinese. The export

trade to Europe and India is now principally confined to that settlement. (*Ainslie's Mat. Indica; Crawfurd's East. Archip.* vol. i. pp. 383—393., vol. iii. p. 348.; *Bell's Review of the Commerce of Bengal, &c.*)

The consumption of sago has undergone an almost incredible increase within the last twenty years, which is wholly ascribable to the reduction in the interval of the oppressive duties by which the article was formerly loaded. — (*Papers published by the Board of Trade.*)

SA'GUM. The military dress of the Roman magistrates and dignitaries; a cloak fastened at the breast with a clasp. The same name was given to the ordinary dress of several barbarous nations. Thus Tacitus says of the Germans, *tegumen omnibus sagum;* and Varro and Diodorus Siculus represent it as the costume of the Gauls.

SA'HLITE. In Mineralogy, a variety of augite from the silver mine of Sahla in Sweden.

SAIL. A surface obtained by canvass, mat, or other material, by the action of the wind on which, when extended, the vessel is moved. A sail extended by a yard hung (*slung*) by the middle and balanced, is called a *square sail:* a sail set upon a gaff or a stay, is called a *fore and aft sail;* which terms refer to the position of the yard, gaff, or stay, when the sail is not set. The upper part of every sail is the *head*, the lower part the *foot;* the sides in general are called *leeches;* but the weather or side edge of any but a square sail is called the *luff*, and the other edge the *after leech*. The upper two corners are *earings*, but that of a jib is the *head;* the lower two corners are in general *clues;* the weather clue of a fore and aft sail, or of a course while set, is the *tack*. The edges of a sail are strengthened by a rope called the *bolt rope*. The ropes at the upper and lower edges are the head and foot ropes of the sail. The canvass or sail-cloth is made in *bolts;* and the qualities are numbered from No. 1., which is the strongest, and is used for storm sails, to No. 8., which is used for the smallest sails, as small studding sails, &c., which the seamen commonly call *flying kites*. The cloths in a square sail are seamed vertically; in a fore and aft sail they are parallel to the after leech. In this way the strain of the sheet diffuses itself over the canvass both along and across the cloths. Discussions have, however, arisen as to the best mode of seaming. When a seam opens, the sail often splits. Captain Cowan took out a patent for *horizontal* seaming; he remarks (*Essay on the Construction of Sails, &c.*) that such sails when they split remain full, and are less liable to blow away, and that they also were found to last much longer. The plan, however, has not been approved. *Diagonal* seaming, which has also had its advocates, is defective in principle; for it must bring the strain of a sheet either on a single cloth, or entirely across the stitches.

Sails take their names from the mast, yard, or stay upon which they are stretched. Thus, the principal sail extended upon the main mast is called the *main sail;* the next above, which stands upon the main-top mast, is the *main-top-mast sail;* above which is the *main-top-gallant sail;* and above all, the *main royal*. In like manner, there are the *fore sail*, the *fore-top sail*, the *fore-top-gallant sail*, and the *fore royal;* and similar appellations are given to the sails supported by the *mizzen* or after mast. The *main-stay sail*, *main-top-mast stay-sail*, &c., are between the main and fore masts; and the *mizzen stay-sail*, *mizzen-top-mast stay-sail*, &c., are between the main and mizzen masts. Between the fore-mast and bowsprit are the *fore stay-sail*, the *fore-top-mast stay-sail*, the *jib*, and sometimes a *flying jib* and *middle jib*. Square sails extended by yards under the bowsprit and jib-booms are called *sprit sails;* and the *studding sails* are those which are extended upon the different yards of the main mast and fore mast.

To *make* sail, is to set sail. To *shorten* sail, is to take in some sail. To *loose* sails, is to spread or hang out the sails that had been furled to air them, or for the purpose of setting afterwards. To *strike* sail, is to lower the yard or gaff of a sail when set, in token of salute.

The common theory of sails which assumes the impact of columns of air is radically defective; for it is a fact familiar to sailors that the reef points, or any light stuff by accident in the same situation, hang vertically in the hollow of the sail, as in a calm, thereby proving that the sail is filled with a mass of air, quiescent or nearly so, and maintained in a state of statical pressure; whereas if the common theory were true, the points would lie flat to the canvass, as weeds are pressed against the bank of a stream. Hence it follows that (as all sailors believe who have not mixed with their practice the fragments of imperfect theories) there is a certain extent of hollow or *belly* which increases the effect of the sail. It of course adds to the effect of sails to wet them, by swelling the threads and closing the pores: this practice is often resorted to in chase.

SAI'LING. In Navigation, the art of directing a ship on a given line laid down in a chart. It is called *plane sailing* when the chart is constructed on the supposition that the earth's surface (or rather the surface of the ocean) is an extended plane; and *globular sailing*, when the chart is a globular chart, or constructed on the supposition that the earth is a sphere. *See* NAVIGATION.

SAILING ORDER, or ORDER OF SAILING. Any determinate order preserved by a squadron of ships. It usually implies 1, 2, or 3 parallel columns, but is at the disposition of the admiral.

SAINFOIN. (*Hedysarum onabrychis.*) A plant of the family of the *Leguminosæ*. It will not thrive well except when the soil or subsoil is calcareous, and is consequently not generally met with in this country; though it is extensively cultivated on the Cotswold Hills, and on the chalk soils of Dorset, Hants, Wilts, &c. It generally remains for eight or ten years,— a much longer period than it does in France. It is made into hay, the after crop being eaten by cattle.

SAINT JOHN, KNIGHTS OF; or HOSPITALLERS. A military order of religious persons. They derived their name from a church and monastery dedicated to St. John the Baptist, founded at Jerusalem about 1048 by merchants from Amalfi, the brotherhood of its members being devoted to the duty of taking care of poor and sick pilgrims. The order was instituted as a military brotherhood by Raymond du Puy, its principal, early in the 12th century. It was divided into three ranks—knights, chaplains, and servitors; and in its military capacity it was bound to defend the church against the infidels. It possessed various possessions and settlements at different times in different parts of the East. In the 13th century, being driven from Palestine, the knights of this order fixed their principal seat first in Cyprus, and afterwards at Rhodes, where they remained from 1309 to 1522, when the island was captured by Solyman II. After several changes of settlement, they were fixed in 1530 by Charles V. at Malta and its dependent islands; whence they took the name of Knights of Malta. Here they maintained themselves until 1798, when the island was taken by Napoleon. The order, however, continued to subsist, notwithstanding the loss of its sovereign possessions both in Malta and in Tuscany: the seat of the chapter is now at Ferrara. Before the French Revolution the number of knights was estimated at 3000. The temporal powers of the order were chiefly concentrated in the hands of the grand master; but he was, in fact, controlled by the governors of the eight languages. These were, of Provence, Auvergne, France, Italy, Aragon, Germany, Castile, and England. The lands were divided into priories, commanderies, and bailliages. The spiritual power was exercised by the chapter, consisting of eight ballivi conventuales. The knights were under the rules of the order of St. Augustine; but Protestants were not bound to celibacy. They were required to be necessarily of good descent; but those whose proofs of noble ancestry were unquestionable were termed *cavalieri di giustizia*, while others who could not show such proofs might be admitted on account of their merits as *cavalieri di grazia*. *See* HOSPITALLERS.

SAINTS. (Lat. sancti, *holy persons.*) Pious men, who, according to a custom early prevalent among Christians, were commemorated with honour after their death in the services and ceremonies of the church. This distinction was originally applied to the apostles and eminent martyrs and confessors, whose places of burial were regarded with pious affection by the faithful in the neighbourhood, and memorials or relics of whom were carefully cherished among them. The observance of particular days in the honour of the saints was also a very early custom; but the natural feeling which prompted this and other tributes of gratitude and respect towards them became gradually corrupted. The intercession of the saints was supposed to have power with God, and individuals put themselves under the especial patronage of one or more amongst the number, which in later times was vastly augmented, giving to them the honour and worship due to God alone, and conceiving themselves sufficiently protected by the influence of their prayers. It was affirmed that miracles were performed at their tombs and by their relics, and the greatest rivalry and contention arose between the votaries of the shrines of different saints, and sometimes those of the same. For the manner of enrolment among the number of saints, see art. CANONIZATION. (See *Bingham and Palmer's Origines Liturgicæ*, as to the progress of the invocation of saints in the church, vol. i. 276, &c.)

SAINT SIMONIANS. Claude Henri, Count de S. Simon, of the ancient family of that name, born in 1760, was engaged during the greater part of his life in a series of unsuccessful commercial enterprises, a traveller, and in the early portion of his life a soldier in America; but having dissipated a considerable fortune, and been unable to draw the attention of the public to a variety of schemes, political and social, which he was constantly publishing, he attempted suicide in 1820: he lived, however, a few years longer, and died in 1825, leaving his papers and projects to Olinde Rodriguez. St. Simon's views of society and the destiny of mankind are contained in a variety of works, and especially in a short treatise entitled

the *Nouveau Christianisme*, published after his death by Rodriguez. This book does not contain any scheme for the foundation of a new religion, such as his disciples afterwards invented. It is a diatribe against both the Catholic and Protestant sects for their neglect of the main principle of Christianity, the elevation of the lower classes of society; and inveighs against "l'exploitation de l'homme par l'homme," the existing system of individual industry, under which capitalist and labourer have opposite interests and no common object. The principle of association, and just division of the fruits of common labour between the members of society, he imagined to be the true remedy for its present evils. After his death these ideas were caught up by a number of disciples, and formed into something resembling a system. The new association, or St. Simonian *family*, was chiefly framed by Rodriguez, Bazar, Thierry, Chevalier, and other men of talent. After the revolution of July, 1830, it rose rapidly into notoriety, from the sympathy between the notions which it promulgated and those entertained by many of the republican party. In 1831, the society had about 3000 members, a newspaper (the *Globe*), and large funds. The views of the St. Simonian family were all directed to the abolition of rank and property in society, and the establishment of associations (such as the followers of Mr. Owen in this country have denominated co-operative), of which all the members should work in common and divide the fruits of their labour. But with these notions, common to many other social reformers, they united the doctrine, that the division of the goods of the community should be in due proportion to the merits or capacity of the recipient. Society was to be governed by a hierarchy, consisting of a supreme pontiff, apostles, disciples of the first, second, and third order. It was not until about this period (1830) that they begun to invest these opinions with the form and character of a religion; but shortly after having done so they went into great extravagances. There was a disunion among them as to the fittest person to preside in the society; and consequently Messrs. Bazar and Enfantin divided, for some time, the duties and dignity of the "Supreme Father," as he was termed. But on the 19th Nov. 1831, Bazar and many others left the society, of which Enfantin remained the supreme father. Their doctrines and proceedings now became licentious and immoral to the last degree. On the 22d Jan. 1832, the family was dispersed by the government. Enfantin and Rodriguez were tried on various charges, and imprisoned for a year. The former afterwards collected again a part of the society at Menilmontant; but it broke up for want of funds. Some former members of the St. Simonian association are now in places of rank and consideration: some of the most extravagant have gone to the East; but Enfantin, we believe, has no followers.

SA'LAMANDER, *Salamandra*. (Gr. σαλαμανδρα.) The name of a genus of Batrachian reptiles, now limited to the terrestrial species of long-tailed Caducibranchiate Batrachians, or those which lose their gills before arriving at maturity, but retain their tails. This appendage is changed in the progress of growth in the true salamander from a compressed to a rounded form. The female brings forth the young alive, which are hatched in the oviduct; and the sexes frequent the water at the season of reproduction. *See* BATRACHIA and TRITON.

SAL AMMO'NIAC. Muriate of ammonia; hydrochlorate of ammonia. A compound of 17 of ammonia and 37 hydrochloric acid. Its name is derived from the Temple of Ammon, in Egypt, where it was originally made by burning camels' dung: it is now largely manufactured in this country. *See* AMMONIA.

SALEP. *See* SALOP.

SAL GEM. Common salt.

SALICA'CEÆ. (*Salix*, the principal genus.) A natural order of Achlamydaceous Exogens, distinguished by a two-valved capsule, and numerous seeds tufted with long hairs. The genus *Salix* comprehends the plants called osiers, sallows, and willows, and is of great economical value, not only for the purposes of the basket-maker, but because several species have a bark which has been found by Davy to contain as much tannin as the oak; and a crystallizable principle called *salicine* has been obtained from *Salix helix* and others, which, according to Magendie, arrests the progress of a fever with the same power as the sulphate of quinia. The poplars, aspens, and abele trees also form a part of this order.

SA'LICIN. A bitter crystallizable substance extracted from willow bark. It exists in several species of willow; and a similar substance has been extracted from the bark of the poplar, especially of the *Populus tremula*. Its ultimate elements are carbon, hydrogen, and oxygen, so that it differs from the vegeto-alkalis in containing no nitrogen.

SA'LIC LAW. The law of that community of the nation of Franks which inhabited the country between the Meuse and the Rhine,—the law of the Ripuarian Franks governing those who dwelt between the Rhine and the Loire. The origin of the name Salian, given to this portion of the Franks and their law, is uncertain: some derive it from the river Saale, in Saxony, on the banks of which they suppose them to have inhabited before the period of their emigration westward. The body of law in question was republished and reformed by Charlemagne in 798, and is still preserved, both in the earlier and in the remodelled shape. The most celebrated portion of it is contained in the title 62. *De Alode*, where it is declared that "no portion of the inheritance in Salic land (terra salica) can fall to females; but that the whole must pass to the males." What those lands were which are intended by the term Salic, has afforded room for infinite discussion among French antiquaries. It is supposed by Ducange that they were those lands which were acquired by Franks at the period of the conquest, and held by military service only. But it seems that the exclusion of females was only to take place where males were to be found in the same degree of kindred to the ancestor. However this may be, the fundamental law which excludes females from succession to the crown of France received, in very early times, the appellation of the Salic law, and was supposed by her lawyers to be derived from the provisions of this ancient code. It was, indeed, a custom prevalent from the earliest times, as we learn from Tacitus, among the Germanic tribes. It was observed in France under the first race; but the first occasion on which it was publicly canvassed was in 1316, when Jeanne, the daughter of Louis Hutin, was excluded from the crown in favour of Philip V., her uncle. In 1328 it was contested by Edward III., who claimed by a prior title to Philip of Valois, if females were admissible; being the son of Isabella, sister of Louis Hutin. From this pretension arose the wars between England and France, which occupied the whole of the following century. In 1593 the famous arrêt of the parliament of Paris was pronounced, by which all treaties made to transfer the crown to a foreign dynasty were declared null, as contrary to the "Salic" and other fundamental laws. The same law has been recognized in all countries of which the crown has devolved upon the royal house of France, and forms now the foundation of the pretensions of the Infante Don Carlos to the throne of Spain. It was also considered as established in those great fiefs of the crown of France which had been granted to princes of the blood by way of apanage; and by this means, on the death of Charles duke of Burgundy, leaving a daughter only, the dukedom of Burgundy proper reverted to Louis XI. as a male fief. (See *Mem. de l'Ac. des Inscr.* vol. xx.; *Meyer's Origines Judiciaires; Hallam's Middle Ages.*)

SALICO'QUES. The French term for the family of Macrourous or long-tailed Crustacea of which the shrimp (*Crangon vulgaris*) is the type.

SA'LIENT. (Lat. salio, *I leap.*) In Heraldry, a term used to describe a beast when represented as leaping or springing.

SALIENT ANGLE. In Geometry and Fortification, an angle of a polygon projecting *outwards* in reference to the centre of the polygon. An angle pointing *inwards* is called a *re-entering angle.* All the angles of any regular figure, as the triangle, square, hexagon, &c., are salient.

SALIE'NTIA. (Lat. salio, *I leap.*) The third order in the Mammalogical system of Illiger, including the Marsupial genera *Hypsiprymnus* and *Halmaturus*, or the potoroos and kangaroos, whose progression is by successive leaps.

SALI'FEROUS ROCKS. The new red sandstone system of some geologists. *See* GEOLOGY.

SALIFI'ABLE BASE. This term, which is of frequent occurrence in chemistry, is chiefly applied to those metallic oxides which combine in definite proportions with the acids, so as to form distinct salts: ammonia, and the vegeto-alkalis are also, upon the same principle, salifiable bases.

SA'LII. The Roman flamens, or peculiar priests of Mars. They were twelve in number, and were instituted by Numa to guard the *ancile*, or sacred shield of Mars. They used on solemn occasions to proceed through the city dancing, whence they derived their name (from *salire*, to dance).

SALI'VA. (Lat.) The fluid secreted into the mouth by the salivary glands; its principal use is to lubricate the parts, and to assist in rendering the food of a proper consistency to be swallowed.

SALIVA'TION. The excessive flow of saliva which is produced by the continuous use of mercury and of some other remedies.

SA'LIX (Lat. *a willow*), is a genus of plants consisting of numerous species, all either trees or bushes, occurring abundantly in all the cooler parts of the northern hemisphere. Some of them, like *S. alba*, acquire the dimensions of the largest forest trees; others are lost among the grass with which they grow, as *S. herbacea*. They are the last kind of ligneous plants that disappear before the rigours of an arctic climate, the only tree found on Melville Island, nine inches high, having

been a willow (*Salix arctica*). Few extend into warm regions, the *Salix babylonica*, or weeping willow, being the best known instance. Their timber, when they form any, is light, tough, soft, and unfit for purposes of construction; it is chiefly used for turnery, and for coarse in-door purposes. Many species have long flexible shoots, and are called osiers, under which name they are extensively employed by the workers in wicker; others are not flexible, but form small trees or rough bushes, named sallows. The latter, called *Saules marçeaux* by the French, yield the best kind of charcoal for military purposes; they are all, however, burnt for the preparation of this substance. The bark of *S. helix*, *fragilis*, *pentandria*, and others, has been found useful in intermittent fevers; and as these maladies are most common in the low marshy places where salices abound, it has been supposed that they are the means which the Creator has given us for protecting ourselves against such disorders. The species intermix very freely, forming mules and hybrids, which have led botanists to create a prodigious number of false species.

SALLY PORTS, in Fortification, are underground passages leading from the inner works to the outward ones, for the troops to sally out. They are othewise called *postern gates*.

SA'LMON. (Lat. salmo.) The excellent and highly valuable fish so called in England is the *Salmo salar* of Linnæus, not of Rondeletius. Both species exist in our rivers, the latter having been recognizably and accurately defined under the name of *Salmo eriox*, or bull trout, which it is to be hoped will be retained for this species, notwithstanding that the name of *Salmo salar* may have been applied to it by the older ichthyologist.

The normal locality of the salmon is at the mouth or estuary of the larger rivers, which, in the season of sexual excitement, they ascend, sooner or later, in the summer months, according as circumstances may influence their coming into breeding condition. At first they ascend only so far as the tide wave reaches, and retire with the ebb; but as the quantity of roe and milt increases, the instinct which teaches the fit locality for oviposition becomes more imperative, and few are the natural obstacles which the salmon does not overcome in its endeavour to reach it.

The great value of the fish renders an accurate knowledge of it, under the disguise of its immature form and markings, of the highest importance; but the difficulties which attend the observation of the migratory inhabitants of the water have only very lately been overcome in the present instance. The proof that the small Salmonoid fish, called the parr, is, as many naturalists had suspected, the young of the salmon, has been elicited by the careful and repeated observations and experiments of Mr. Shaw of Drumlanrig, of which the following condensed account is taken from the *Transactions of the Royal Society of Edinburgh*.

In the river Nith, Dumfries, the salmon oviposits in the month of January. On the 10th of January, Mr. Shaw observed a female salmon of about 16 lbs. weight, and two males of at least 25 lbs., engaged in depositing their spawn. The spot which they had selected for that purpose was a little apart from some other salmon which were engaged in the same process, and rather nearer the side of the stream, although still in pretty deep water. The two males kept up an incessant conflict during the whole of the day for possession of the female, and in their struggle frequently drove each other almost ashore, and were repeatedly on the surface, displaying their dorsal fins and lashing the water with their tails. — The female throws herself at intervals of a few minutes upon her side; and while in that position, by the rapid action of her tail she digs a receptacle in the gravel for her ova, a portion of which she deposits, and again turning upon her side she covers it up by the renewed action of the tail; thus alternately digging, depositing, and covering the ova, until the process is completed by the laying of the whole mass, an operation which generally occupies three or four days. The embryo fish, conspicuous by the two dark eye-specks and the vascular vitelline sac, presented some appearance of animation in the ovum on February 26th, that is, forty-eight days after having been deposited; and on 8th April, or 90 days after impregnation of the ova, the young were excluded. The head is large in proportion to the body, which measures $\frac{5}{8}$ths of an inch in length; the vitellicle is $\frac{2}{8}$ths of an inch in length, and resembles a light red currant; the tail is margined like that of the tadpole, with a continuous fin running from the dorsal above to the anal beneath. The vitelline sac and its contents are absorbed by the 30th May, or in about fifty days, until which time the young fish does not leave the gravel. The terminal fringe-like fin now begins to divide itself into the dorsal, adipose, caudal, and anal fins; and the transverse bars on the sides of the body make their appearance. At this period the young salmon measures an inch in length, and is very active, and continues in the shallows of its native stream till the following spring, when it has attained the length of from three to four inches, and is called the "May parr:" they now descend into deeper parts of the river, but remain there over the second winter. In April, the caudal, pectoral, and dorsal fins assume a dusky margin; the lateral bars begin to be concealed by a silvery pigment; and the migratory dress, characteristic of the salmon fry or smolt, is assumed. The fish now begin to congregate in shoals, and to migrate seaward.

The full-grown salmon averages a weight of between 25 lbs. and 35 lbs.; but instances are recorded of their attaining to 55 lbs., 60 lbs., 70 lbs., 74 lbs., and 83 lbs. The last-cited weight was that of a female salmon, which came into the possession of Mr. Groves, the fishmonger, in Bond Street, about the season of 1821; it was a short fish for the weight, but of very unusual thickness and depth. When cut up, the flesh was fine in colour, and proved of excellent quality. *See* FISHERIES.

SA'LMONOIDS, *Salmonidæ*. A family of soft-finned Abdominal fishes, of which the salmon is the type, having their upper jaw formed in the middle by the intermaxillary, and at the sides by the maxillary bones, both of which support teeth; they are also characterized by a posterior small adipose dorsal fin, and the body is covered with regular cycloid scales. They pass, by almost imperceptible gradations, into the Clupeoid or herring family, with which they have been united by M. Agassiz, to form a common group termed *Halecoids*. Those species of Salmonoids which, like the Clupeoids, inhabit the sea, not only approach the land, but ascend the rivers to near their source, in order to deposit their ova.

SALO'N, or SALOON. (It. salone.) In Architecture, a large state apartment; or, as its name imports, a great hall, or one for the reception of works of art, and usually running up through two stories of a house. *Salon* is also applied to the reunions of the French capital, which have always exercised considerable influence upon the country in all that relates to fashion, literature, and even politics. M. Guizot's admirable little work upon the Salons of Paris is well known. It was recently well reviewed in the *Journal des Débats*.

SA'LOP. The prepared root of the *Orchis mascula*. It consists principally of a modification of gum, much resembling *tragacanth*, with a small quantity of starch; it is sometimes used as an article of food.

SALP, *Salpa*. (Lat. salpa, *a stock-fish*.) A name applied to a genus of soft-shelled or tunicated Acephalous Mollusks, which float in the sea, protected by a transparent gelatinous coat, perforated for the passage of water at both extremities.

SA'LPINX. (Gr. σαλπιγξ, *a trumpet*.) The Eustachian tube, or channel of communication between the mouth and ear.

SAL SEIGNETTE. Tartrate of potassa and soda. *See* ROCHELLE SALT.

SALT. (Lat. sal, Germ. salz.) This term, though in ordinary language limited to common salt, or sea salt, is applied in chemistry to all combinations of acids with alkaline or salifiable bases. The term has also been extended to certain binary combinations of chlorine, iodine, bromine, and fluorine with the metals; and these have been called *haloid salts* (from ἁλς, *sea salt*, and ειδος, *form*), inasmuch as modern chemistry has taught us that sea salt belongs to this class. Certain definite combinations of the sulphurets with each other have of late been called *sulphur salts;* but the former appellation of *double sulphurets* is, perhaps, more properly applicable to such compounds.

Sea salt is a compound of 1 equivalent of sodium = 24, and 1 of chlorine = 36; its equivalent, therefore, is (24 + 36) = 60: and it is a chloride of sodium. The circumstances which gave rise to the notion of its containing muriatic acid and soda, and being therefore a muriate of soda, will be apparent by reference to the article MURIATIC ACID. For rock-salt, *see* GEOLOGY.

The nomenclature of salts has reference to the acids which they contain; *sulphates*, *nitrates*, *carbonates*, &c., implying salts of the sulphuric, nitric, and carbonic acids. The termination *ate* implies the maximum of oxygen in the acids, and *ite* the minimum: thus the salts of sulphurous and nitrous acids are called *sulphites* and *nitrites*. When salts contain 1 equivalent of acid and 1 of base, they are called *neutral salts;* where 1 equivalent of acid is combined with 2 of base, they are termed *basic salts*, *subsalts*, or *disalts;* and where there are 2 equivalents of acid and 1 of base, the salt is a *supersalt*, or *bisalt*. Thus, the terms *subacetate* and *diacetate of lead* are synonymous; so are *supercarbonate* and *bicarbonate of potash*. Many salts are *hydrous;* that is, they contain a definite proportion of water of crystallization; others are destitute of water, and are dry or *anhydrous salts*. Some salts attract moisture when exposed to air, and are said to *deliquesce;* others suffer their water to escape and become opaque, or pulverulent: these are called *efflorescent salts*.

Salt is, next to bread, the most important necessary of life. It is one of the most important British minerals,

and is procured in immense quantities, both from fossil beds and brine springs, in Cheshire and Worcestershire. Previously to the discovery of the fossil beds during the 16th century, and subsequently, a good deal of salt continued to be made by the evaporation of sea water in salt pans, at Lymington and many other places; but the works at these places are now all but abandoned; while not only has the quality of the article in question become greatly improved, but, instead of being imported as formerly, it is now largely exported. The consumption of Great Britain only, exclusive of Ireland, amounts to about 180,000 tons; and the foreign exports to about 300,000 tons per year, of which the United States, Canada, the Low Countries, Russia, Prussia, and Denmark are the chief consumers. Previously to 1823, an oppressive tax of 15*s*. per bushel, or about thirty times the original cost price of the article, was imposed on salt; but in that year it was reduced to 2*s*., and two years subsequently was totally repealed. During the existence of the duty, the retail price of salt was 4½*d*., it is now only ½*d*. per lb.

In ancient Rome, salt was subjected to a duty, *vectigal salinarium* (see Burman, *Dissertatio de Vectigalibus Pop. Rom.* c. 6.); and it has been heavily taxed in most modern states. The *gabelle*, or code of salt laws formerly established in France, was most oppressive. From 4000 to 5000 persons are calculated to have been sent annually to prison and the galleys for offences connected with these laws, the severity of which had no inconsiderable share in bringing about the Revolution.

SA'LTATORY. (Lat. salto, *I leap*.) In Zoology, the extremities of an animal which by their form and proportions are adapted for leaping are called *pedes saltatorii;* as the hind legs of the kangaroo, cricket, &c.

SA'LTIGRADES, *Saltigrada*. (Lat. saltus, *a leap*, and gradior, *I walk*.) The name of a tribe of spiders which seize their prey by leaping upon it from a distance.

SA'LTIRE. In Heraldry, an ordinary in the form of a cross of Saint Andrew: formed by two bends, dexter and sinister, crossing each other. Charges having length (swords, batons, &c.) placed in the direction of the saltire, are said to be borne *saltire-wise*.

SALT MARSH. Land under pasture grasses or herbage plants, subject to be overflown by the sea, or by the waters of estuaries or the outlets of rivers, which in consequence of proximity to the sea are more or less impregnated with sea salt.

SALT MINE. *See* Geology.

SALT OF LEMONS. Binoxalate of potassa is usually sold under this name, and is used for the removal of iron-moulds and other stains from linen; it is generally effectual, and does not corrode.

SALT OF SORREL. Oxalate of potash.

SALTPE'TRE. (Lat. sal, *salt*, and Gr. πέτρα, *a stone*, from its being found in certain stony soils.) Nitrate of potash. An anhydrous salt composed of 1 equivalent of nitric acid = 54, and 1 of potassa = 48. *See* Nitre.

SALT, SPIRIT OF. *See* Muriatic Acid.

SALT SPRINGS. *See* Geology.

SALU'TES. In Military and Naval Discipline, an exhibition of respect performed in different ways, according to circumstances. In the army, the officers salute their superiors by dropping the point of their sword. In the navy, the usual mode of salutation is by firing a certain number of guns, which is regulated according to the rank or station of the individual. (See *Miles's Epitome of the Naval Service of England*, 1841.)

SA'LVAGE, in Mercantile Law, is defined to be a compensation to be made by the shipowners or merchant to other persons by whose assistance the ship or lading may be saved from impending peril, or recovered after actual loss. Salvage may become due—1. On rescue from perils of the sea. In this case, the salvor, or rescuer, has a lien on the goods preserved until a recompence is made him. The amount of this recompence may be fixed by a jury; but if the salvage happen at sea, or between high and low water mark, the court of admiralty has also jurisdiction to fix the amount on suit brought; and by 12 Anne, st. 2. c. 18., and other statutes, summary powers for the same purpose are given to inferior officers in certain cases. 2. On rescue from the hands of enemies. In this case, the old law was, that if a ship was retaken from enemies before it was taken home or condemned by the captor, the original owner could recover her on payment of salvage to the recaptor; but if retaken at a later period, she became lawful prize to the recaptors. But by 13 G. 2. c. 4. s. 18., and other statutes, the right of the original owner has been extended to all cases of recapture. Salvage, on recapture by a king's ship, was fixed, in 1793, at one eighth, and by a private vessel at one sixth.

SALVATE'LLA. (Lat. salus, *health*.) A vein of the arm terminating in the fingers. It was formerly regarded as having peculiar influence on the health when opened.

SAL VOLATILE. Carbonate of ammonia. The term is often applied to a spirituous solution of carbonate of ammonia flavoured with aromatics.

SAMANÆ'ANS, SARMA'NES, GERMA'NES. Names given by different classical writers to a sect of philosophers of India. Clement of Alexandria derives the name from Gr. σεμνος, *venerable*. But it is more probably oriental; the word schamman, in India, signifying a philosopher. The Samanæans are particularly distinguished by those who mention them from the Brahmins. Saint Jerome and Clement of Alexandria represent them as priests of Buddha; and the same name appears in the *Cha-Men* of the Chinese, and *Sammono-Codom* of Siam. (*See* Buddhists.) There is a memoir on the subject by M. de Guignes. (*Mem. de l'Ac. des Inscr.* vol. xxvi. See also *Hist. de l'Acad. des Inscr.* vol. xxxi.; and *Mem.* vol. xl.)

SAMA'RA. An indehiscent superior fruit, being a few-seeded, indehiscent, dry nut, elongated into wing-like expansions; as in the fruit or "key" of the ash-tree, &c. From this root is formed the word *samaroid*, expressing a resemblance to a samara.

SAMA'RITANS. The inhabitants of the city and district of Samaria to the north of Judea. The city was the capital of the kings of Israel; and after the captivity of that portion of the Jewish nation, a colony of Luthites, who are supposed to be Scythians, was settled in the country by the kings of Assyria. It is stated that they were instructed in the Jewish religion by a priest who was sent to them for that purpose by Esarhaddon, in order to avert the anger, as was supposed, of the god of the country. The Samaritans professed belief in the Pentateuch only, but no idolatrous practices are imputed to them; and it was probably their spurious origin which excited against them the jealousy and affected contempt of the Jews, to which many passages of the New Testament so pointedly refer.

SA'MIAN EARTH and STONE. A species of marl from the island of Samos.

SA'MSON'S POST. A strong pillar resting on the kelson, and supporting a beam of the deck over the hold, and thus acting to keep the cargo in its place. Also a temporary or moveable pillar carrying a leading block for various purposes.

SA'MUEL, BOOKS OF. Two canonical books of the Old Testament. The first twenty-four chapters of the first book contain all that relates to the prophet Samuel himself, beginning with the government of Eli. The second book, together with the remainder of the first, carries on the history of the Jews to the death of David. It is traditionally said that the prophet Samuel composed the first part, and the prophets Gad and Nathan the remainder.

SANCTIFICA'TION, in Theology, denotes the state of those Christians who, having lost the inclination to vice, have become pure and holy, and wholly devoted to works of goodness. This state is produced by the special operation of the Holy Ghost, and ensues upon *justification;* which see.

SA'NCTUARY. (Lat. sanctus, *holy*.) The innermost chamber of the tabernacle, and in after times of the temple, among the Jews, in which was kept the ark of the covenant, and which was regarded as the especial residence of the Most High. It is also called the Holy of Holies, and was never entered except once a year, and then only by the high priest on the day of the great expiation of the sins of the people. For the mystical signification of this act, see Hebr. ix. 24.

By the Roman Catholics, the part of the church immediately round the altar is called the sanctuary, which is supposed in many respects to bear an analogy to that of the Jews.

From the time of Constantine downwards, certain churches have been set apart in many countries to be an asylum for fugitives from the hands of justice. This seems to have been originally intended only to prevent sudden violence, and to give time for the regular administration of the law, and perhaps, in the case of certain delinquencies, for the intercession of the church. But in England, particularly down to the Reformation, any person who had taken refuge in a sanctuary was secured against punishment, if within the space of forty days he gave signs of repentance and subjected himself to banishment.

SAND. (Germ.) Finely divided silicious matter constitutes common river and sea sand; particles of other substances are often blended with it, and sometimes it becomes calcareous from the prevalence of carbonate of lime.

SA'NDALS. A species of slippers worn by the ancient Jews, Greeks, and Romans. They consisted of a sole with a hollow part at one extreme, to embrace the ancle and leave the upper part of the foot bare. Originally sandals were made of leather; but they afterwards became articles of great luxury, being made of gold, silver, or other precious stuff, and most beautifully ornamented.

SA'NDARACH. The resin of *Callitris quadrivalvis* is so called. The powder of this resin is sometimes used under the name of *pounce*, to prevent ink from sinking into paper.

SANDEMA'NIANS. In Ecclesiastical History, the followers of Robert Sandeman, who published his opinions

in 1757 in a series of letters. They are of a highly Antinomian character; and their distinguishing opinion is well expressed in Sandeman's epitaph, where "the ancient faith," for which he "long and boldly contended," is said to be "that the bare work of Jesus Christ, without a deed or thought on the part of man, is sufficient to present the chief of sinners;" faith, according to them, being only a simple assent to the divine testimony concerning the Redeemer. The real founder of the Sandemanians was John Glass, the father-in-law of Sandeman. The adherents of the former have retained the name of Glassites, but are confined entirely to Scotland, from which church their founder originally dissented; whereas the followers of Sandeman have extended to England and America as well as Scotland. This sect has never been numerous, and it is now, we believe, nearly extinct.

SA'NDERLING. The name of a small wading bird, a species of *Tringa* (*Tr. arenaria*, Ill.), which frequents many of our shores, but is not a plentiful bird.

SANDIVER. The impurities which collect upon glass during its fusion in the furnace are so called.

SA'NDPIPER. A name applied to different species of the genus *Tringa*, but properly restricted to the *Tringa hypolecuus* of Linnæus, which is the type of the subgenus *Totanus*.

SA'NDSTONE. Stone composed of agglutinated grains of sand, which may be calcareous or siliceous. *See* GEOLOGY.

SA'NGIAC. A Turkish officer, governor of a sangiacate, or district forming part of a pachalic. There were two hundred and ninety such districts in the Turkish empire before the recent losses of territory on the side of Greece and the Caucasus.

SANGUISO'RBEÆ. (Sanguisorba, one of the genera.) A natural order of herbaceous or undershrubby Exogens, usually combined with *Rosaceæ*, as a sub-order; but apparently distinct, on account of the constantly apetalous flowers, indurated calyx, and solitary or almost solitary carpels. Their general character is that of astringency. Burnet, the *Sanguisorba officinalis*, is sometimes grown as a pasture plant.

SANGUISU'GES, *Sanguisuga*. (Lat. sanguis, *blood*, and sugo, *I suck*.) The name of a family of Hemipterous insects, including those which suck the blood of animals: also applied to a family of Abranchiate Annelidans, of which the leech (*Sanguisuga medicinalis*, Sav.) is the type.

SA'NHEDRIM. (Heb.) The highest judicial tribunal among the Jews, consisting of seventy-one members, including the high priest. Its origin is referred by some writers to the institution by Moses of a council of seventy persons on the occasion of a rebellion of the Israelites in the wilderness. (See *Milman's Hist. of Christianity*, i. 339. &c.)

SA'NIES. (Lat.) A thin, unhealthy, purulent discharge from wounds or sores.

SA'NSCRIT. The learned language of Hindostan. The literal meaning of the word Sanscrita is *polished*, and it is used by grammarians in the sense of "regularly inflected or formed." (*Colebrooke's Remains*, vol. ii. p. 2.) And it is a question whether, in its present form, it was ever a *spoken* language, although the theory of Schlegel is, that it was imported by the conquering or Brahminical caste. It constitutes the most ancient literature of the Hindoos, and is radically connected with the various dialects of Hindostan, so that they may be regarded as more or less deflected from it. Colebrooke, however, is of opinion that "there seems no good reason for doubting that it was once universally spoken in India;" and he says, that "those who are learned in Sanscrit, at the present day, deliver themselves with such fluency as is sufficient to prove that it may have been spoken in former times with as much facility as the contemporary dialects of the Greek language, or the more modern dialects of the Arabic tongue." Nine tenths of the "Hindustani," it is said, may be traced to the Sanscrit; the remaining tenth is thought to be, perhaps, founded on the old "Hindi" language, which Sir W. Jones thought anterior to it, conceiving the Sanscrit to have been introduced by conquerors in some very distant age. In the Hindoo drama, the gods and saints are made to speak in Sanscrit; while women, benevolent genii, &c. speak another dialect, and the lower personages a third. (See also *Professor Wilson's Hindoo Theatre*, Introduction.) The attention of European inquirers was directed to the Sanscrit and its cognate language by Sir William Jones. Since his time the study has made great progress in England, where it has been especially furthered by the labours of Houghton, Wilkins, and Wilson; and more in Germany, where Frederic Schlegel (*Sprache, &c. der Indier*, 1808) was the first to excite the spirit of investigation. He was followed by his brother, A. W. Schlegel (who edited the *Bhagavat Gita*, translated into English by Mr. Wilkins), and many others. Among recent German philologists, Bopp deserves the highest name for his researches in this direction. (See *Quart. Rev.* vol. xlv. &c., where it is said that in the course of thirty years nearly 700 works on, and translations from the Sanscrit, have appeared.) The intricate connection of Sanscrit with the principal varieties of the Caucasian speech, and especially the Zend, Greek, and Sclavonic, has greatly added to the interest respecting it.

SANS-CULOTTES, or BREECHESLESS. A name first given in ridicule to the Jacobins and other extravagant patriots in the French Revolution, and afterwards assumed by them as a title of honour; like the old nickname of "gueux" (*beggars*), in which the revolters of the Netherlands prided themselves. We have never been able to ascertain the real history of this famous appellation, but we believe that Camille Desmoulins was one of the first who rendered it popular: his blasphemous application of it at his trial is well known. It acquired great celebrity after the "journée" of the 20th June, 1792, when one of the principal standards borne by the insurgents was a pair of black breeches, with the inscription, "Tremblez, tyrans! voici les Sans-Culottes." Subsequently the French nation adopted it with the utmost gravity in the original Republican calendar. The five supernumerary days (the twelve months containing thirty a piece), were named Sansculottides; and were festivals dedicated to "Genius," "Labour," "Actions," "Rewards," "Opinion." In Leap-years there was to be a sixth Sansculottide, the festival of the Revolution. Future generations will find some difficultyin believing the narrative of the ludicrous farces with which national caprice interspersed the great tragedy of the French Revolution.

SA'NTALIN. The colouring matter of red sandal or saunders wood, from which it is separated by digesting the rasped wood in alcohol, and then adding water to the tincture; it falls in the form of a bright red precipitate, soluble in alcohol and in alkaline solutions.

SA'NTONIN. A proximate vegetable principle, obtained from the seed of the *Artemisia santoniea*. It is white, crystallizable, bitterish, and very little soluble in water, but more so in alcohol.

SAP. The fluid which is absorbed by the roots from the earth, then sent upwards into the stem, and afterwards conveyed from the leaves, where it is assimilated and altered, to the bark. In its crude state it consists of little except water holding earthy and gaseous matter in solution, especially carbonic acid; but as it rises through the tissue of the stem it dissolves the secretions it meets with in its course, and thus acquires new properties, so that by the time it reaches the leaves it is entirely different from its state when it first enters the root. The course taken by the sap in its passage through the stem is by the whole of the tissue included within the bark, provided it is all permeable; but as, in many plants, the central part of the stem becomes choked up with solid matter deposited in the tissue, it usually happens, especially in trees, that the course of the sap is confined to the outer part of the wood, hence called sapwood. It is not certainly known through what kind of tissue the upward motion of the sap takes place, but it is probable that it is carried onwards through all the tubes and vessels of the wood and their intercellular passages. The dotted vessels of the wood seem more especially destined to fulfil this office when the sap is in rapid motion; but as they afterwards become empty, while the ascent of the sap continues, there can be no doubt that the woody tubes or pleurenchyma offer the most constant means by which the sap is conveyed. In Fortification, *sap* is a trench or approach made under cover of gabions, &c.

SAPAN WOOD. A dye-wood produced by certain species of *Cæsalpina*. It has long been used in India, and resembles Brazil-wood in its colour and properties.

SAP GREEN. The inspissated juice of the berries of the buckthorn (*Rhamnus catharticus*). It is used by water-colour painters as a green pigment.

SAPHE'NA. (Gr. σαφης, *visible*.) The large vein of the leg which ascends over the external ancle.

SAPINDA'CEÆ. (Sapindus, one of the genera.) A natural order of exotic trees and shrubs, the larger part of which occur in South America. They usually have compound leaves and inconspicuous flowers, resembling those of European maples; and many of them are climbing plants. The order is poisonous in various degrees; nevertheless, the arillus of *Blighia sapida* is an esteemed fruit in Africa and the West Indies, where it is called the *akee*. The most singular property observed in the order is that of having an astringent quality, and forming a lather when agitated in water, whence the name of the typical genus, — from sapo, *soap*.

SA'PONIN. A peculiar substance contained in the root of the *Saponaria officinalis*. It is the cause of the lather which that root forms with water.

SAPOTA'CEÆ (Sapota, the name of one of the species), are a small natural order of Exogenous trees, inhabiting the West Indies and other tropical countries. They in some cases produce eatable fruits, known by the colonial names of sapodilla, marmalade apple, star apple, Surinam medlar, &c. Their juice is white, like milk; and, unlike the secretions of most lactescent families of plants, may be used for alimentary purposes. The fruit of some

yields a greasy substance; whence one of them, *Bassia*, has gained the name of *shea*, or butter tree, in Africa.

SAPPARE. In Mineralogy, a term applied to the *cyanite*.

SAPPERS AND MINERS, ROYAL. The name given to the non-commissioned officers and privates of the corps of Royal Engineers. Their duties consist in building fortifications, in executing field works, and in performing similar operations, under the direction of their superior officers. They were first embodied at the end of the American war, under the name of "Royal Military Artificers;" and after being formed into independent companies, were stationed at Portsmouth, Chatham, and some other military and naval arsenals. In 1812 they received their present designation; and, at the same time, an institution was formed at Chatham for instructing the men in all the duties of military engineering. This corps consists of 13 companies, each of 68 men: some of which are employed in the colonies; others in the mechanical operations connected with the survey at present carried on by the Board of Ordnance; and others remain at Sandhurst and Addiscombe, to execute the various military works undertaken for the instruction of the cadets of these seminaries.

SA'PPHIC. The name given to a species of verse; from Sappho, the famous Greek poetess, by whom it was said to be invented. It consists of eleven syllables of five feet, of which the following is a plan: —

–⏑ | – – | –⏑⏑ | –⏑ | –⏑ |.

This measure was afterwards introduced into Latin, and received, as the reader is aware, great improvements in the hands of Horace and Catullus. The rules for the composition of Greek are much less strict than those for the composition of Latin sapphics. The sapphic strophe consists of three sapphic verses, followed by a *versus Adonicus*, or Adonian verse; which see. This species of verse has been successfully imitated in German and English.

SA'PPHIRE. (Gr. σαφειρος.) A very hard gem, consisting essentially of crystallized alumina. It is of various colours; the *blue* variety being generally called the sapphire, the *red* the oriental ruby, the *yellow* the oriental topaz.

SAPRO'PHAGANS, *Saprophaga*. (Gr. σαπρος, *decomposing matter*, and φαγω, *I eat*.) The name of a tribe of Coleopterous insects, comprising those which feed on animal and vegetable substances in a state of decomposition.

SA'PWOOD, is the external part of the wood of Exogens, which, from being the latest formed, is not filled up with solid matter, or with the colouring principles which are deposited in wood after a certain time. For these reasons, sapwood is that through which the ascending fluids of plants move most freely; and not being solidified by the earthy and other substances eventually incorporated with wood, is quickly decomposed when exposed to the action of air and moisture. Hence for all building purposes the sapwood is, or ought to be, removed from timber. The sapwood or unsolidified wood of all trees is much the same in its power of resisting decomposition, that of the oak and lignum vitæ perishing as quickly as poplar and other valueless timber; and chemists have ascertained that if the hardest heartwood is reduced to its original condition of sapwood by the abstraction of the matter of solidification, all those properties which give heartwood its value are destroyed.

SA'RABAÏTES. A kind of oriental monks or cœnobites, described by Cassian in his *Institutions;* and supposed to be the same with those called Remoboth by St. Jerome (Epist. xviii.) and Eust., and characterized as vicious and ignorant. They seem to have been seceders from the ordinary monastic life, who formed a species of society rather resembling that of the Moravians of the present day, and without community of goods. (*Waddington's Hist. of the Church*, ch. xix.)

SA'RABAND. (Span.) In Music, a composition in triple time very similar to a minuet. When denoting music for the dance, it is to the same measure which usually terminates when the beating hand rises; being thus distinguished from the *courant*, which ends when the hand falls.

SARCOCE'LE. (Gr. σαρξ, *flesh*, and κηλη, *a tumour*.) A tumefaction of the testicle.

SA'RCOCO'LLA. (Gr. σαρξ, and κολλα, *glue*.) The concrete juice of the *Penæa sarcocolla*, a plant growing in the northern parts of Africa. It somewhat resembles gum arabic; but it is soluble in alcohol, and its aqueous solution is precipitated by tannin.

SA'RCOLITE. (Gr. σαρξ, and λιθος, *a stone*.) A variety of zeolite of a flesh colour.

SARCO'LOGY. (Gr. σαρξ, and λογος, *a discourse*.) The history or doctrine of the fleshy parts of the body.

SARCO'PHAGUS. (Gr. σαρξ, and φαγω, *I consume*.) In Antiquities, a stone receptacle for a dead body. The name originates in the use of the lapis Assius, stone of Assos (in Asia Minor), said to have been prepared in antiquity for this purpose, on account of its supposed property of corroding dead bodies, so as to consume them entirely in forty days; which, together with other incredible qualities, is ascribed to it by Theophrastus and Pliny. One of the most celebrated specimens of this object of art is the great sarcophagus taken by the British in Egypt in 1801, commonly called that of Alexander: it is deposited in the British Museum. Dr. Clarke, the traveller, wrote an essay to prove that the Macedonian conqueror had really been entombed in it; but this opinion seems unfounded.

SARDO'NIC LAUGH. A convulsive laugh, said to have been first observed in those who ate the herb *sardonia*, which grows in Sardinia.

SA'RDONYX. (Gr.) A reddish yellow or orange coloured chalcedony or carnelian; it is often blood red by transmitted light.

SA'ROS. An ancient astronomical period, the origin and exact length of which are unknown, though they have been the subject of much disputation. George Syncellus, who wrote in the eighth century, cites a passage from Berosus, reported by Julius Africanus, in which mention is made of three periods, — the *Sossos*, the *Neros*, and *Saros;* and the Saros is stated to be 3600 years. According to Lalande (*Astronomie*, § 1572.), Syncellus also cites Anianus and Panodorus, who assigned the lengths of these periods as follows: — the Sossos, 60 days; the Neros, 600 days; and the Saros, 3600 days, or 9 common years, 10 months, and 11 days. Legentil, after Fugeres, supposes the Saros to be 10 years; Freret supposed it to be 19¾ years; Giraud, 3600 Julian months, which make 3711 lunations, or 31 years. Suidas states that the Saros was a period of lunar months equal to 18½ years; and Halley (*Phil. Trans.* No. 194.), adopting the same notion, and supporting himself by a passage in Pliny, supposes it to be identical with the lunar period of 18 years, or rather of 223 lunations, which corresponds almost exactly to 242 *nodical* revolutions of the moon (*see* MOON), and consequently brings back the eclipses in the same order. But Goguet (*Origine des Loix, &c.*) remarks, that the statement of Suidas is not supported by that of any ancient author; and that there is no reason to suppose that Pliny, in the passage in question, had the Saros in view. By some authors the Saros has been confounded with the *Metonic cycle*.

SARRACENIA'CEÆ (Sarracenia, one of the genera), are curious herbaceous plants, inhabiting the bogs of North America, and having their leaves hollowed out into tubes or pitchers open at the upper end. Their flowers are something like those of *Papaveraceæ*, to which they are doubtless allied.

SARSAPARI'LLA. The root of the *Smilax sarsaparilla*. Several varieties of this drug are imported from South America: that which is now generally preferred is the reddish fibrous root, known in the market under the name of *Jamaica* or red sarsaparilla. What is termed *Lisbon* sarsaparilla is less fibrous, and more mealy and white in the interior. This root, though long employed in medicine, seems only lately to have been properly estimated. It was formerly regarded as a specific in syphilis; but this opinion is now given up, and it is used as a powerful and valuable alterative medicine in many disorders of debility, but more especially in those cachectic habits which present symptoms formerly mistaken for venereal — such as pains of the bones, nodes of the periosteum, loss of strength and flesh, and other characters of what is sometimes called a broken constitution. In these cases a course of sarsaparilla has often effected a cure, especially if resorted to in time, when all other remedies, and more especially mercurials, had failed. It must be taken in pretty large doses, that is, in quantities not less than an ounce to an ounce and a half a day, and persevered in for six, eight, or ten weeks; or a quantity of extract or syrup, or other preparation equivalent to that weight of the dried root: a concentrated liquid extract, and a syrup, are now prepared, which are the best forms. They are apt to disagree with weak stomachs; but generally, by proper management and perseverance, this difficulty may be got over. Where it agrees, the strength is gradually regained, the pains and other symptoms abate and vanish; and the only other effect observed is, either that the bowels are rather more open than usual, or the flow of urine or the perspiration increased.

SARTO'RIUS MUSCLE. (Lat. sartor, *a tailor*.) A muscle of the thigh attached at the upper extremity to the edge of the anterior superior spinous process of the ileum, and at the lower to the inner side of the head of the tibia. It is concerned in bending the leg obliquely inwards, and in crossing the thighs; thence called sartorius, or the *tailor's muscle*.

SASH. (Fr. chassis.) In Architecture, a piece of framing for holding the squares of glass in a window. It is of two sorts — viz. that called the French sash, which is hung like a door to the sash-frame; and that in which it moves vertically from being balanced by a weight on each side, to which it is attached by lines running over pulleys at the top of the sash-frame. When in a window both the upper and lower sashes are moveable the sashes are said to be double hung, and single hung when only one of them moves.

SASH-FRAME. In Architecture, the wooden frame into which the sashes are fitted.

SA'SSAFRAS. The wood of the *Laurus sassafras*, a native of North America, and growing abundantly upon the banks of the river Sassafras; whence its name. It has a warm aromatic flavour, and the decoction is diuretic and diaphoretic. It was formerly used in cases of stone in the bladder (hence its name has by some been derived from saxum, *a stone*, and frangere, *to break*). It has also been extolled as an antisyphilitic remedy, and in rheumatic and cutaneous affections: it is now scarcely ever employed except as an ingredient in the compound decoction of sarsaparilla.

SA'SSOLIN. Native boracic acid, from the vicinity of Sasso in Florence.

SA'TAN. A Hebrew word signifying enemy or adversary; and used as such, without any reference to the Evil Power itself, in one or two passages of the Old and New Testament. The equivalent term in Greek for this word is διαβολος, literally *one who accuses or calumniates;* whence the word *devil* is derived.

SATELLI'TE (Lat. satelles, *an attendant*), in the Solar System, is the attendant of a planet; a body which revolves about the planet, and follows it in its orbit round the sun. Hence the satellite is sometimes called a secondary planet, or merely a *secondary;* the planet about which it revolves being the *primary*.

The planets which are accompanied by satellites are the Earth, Jupiter, Saturn, and Uranus. The Earth has one satellite, namely, the Moon; Jupiter has four; Saturn seven; and Uranus certainly two, if not six. For the Earth's satellite, see MOON.

Satellites of Jupiter. — These bodies were first observed by Galileo, and their discovery followed immediately that of the telescope. With a telescope of ordinary power they may be seen (unless when eclipsed by the shadow of the planet, or concealed behind its disc), on any clear night, at different distances from the planet, and arranged nearly in a straight line, in which they appear to oscillate backwards and forwards with different velocities, and performing unequal excursions; so that their arrangement with respect to the planet, or *configurations*, are constantly changing. Sometimes they are observed to pass before Jupiter, in which case they cast a shadow on his disc like a small round black spot, whence they are inferred to be opake bodies illuminated by the sun; at other times they pass behind the planet and are concealed from our view; and all these phenomena occur in regular order, and, with respect to each satellite, after the same intervals of time.

An attentive examination of the apparent motions of the satellites soon renders it evident that they revolve round Jupiter in small but unequal orbits, the planes of which are nearly coincident with that of the equator of the planet, which is inclined in a small angle to the ecliptic. Observation also shows that the motions of the satellites about their primary are regulated by the same laws as are observed by the planets in their revolutions round the sun. The orbits are ellipses of small eccentricity, of which Jupiter occupies one of the foci; the areas described by the radius vector are proportional to the times of description; and the squares of the periodic times are respectively proportional to the cubes of the mean distances. Thus Jupiter and his satellites form a system in miniature entirely analogous to that of the sun and planets.

The satellites are distinguished as the *first*, *second*, *third*, and *fourth*, according to their respective distances from Jupiter, the first being that which is nearest the planet. The following table shows their mean distances (in terms of the equatorial radius of Jupiter), times of revolution, masses as compared with Jupiter, and diameters in English miles: —

Satellite.	Mean Distance.	Periodic Time.	Mass.	Diameter in Miles.
		Days.		
1	6·04853	1·76914	0·000017	2508
2	9·62347	3·55118	0·000023	2068
3	15·35024	7.15455	0·000088	3377
4	26·99835	16·68877	0·000043	2890

The mean distances are found by measuring the angular distances from Jupiter at the time of the greatest elongations, and the masses were determined by Laplace from the theory of gravitation. On account of the minuteness of their apparent diameters it is difficult to determine their true diameters with precision. The second, which is the smallest, at the mean distance of the planet subtends an angle of rather less than 1″; and the third, which is the largest, an angle of less than 1·5″. (*Memoirs Royal Astronomical Society*, vol. iii. p. 301.)

Small as the satellites of Jupiter are in comparison of the primary planet, they are in themselves bodies of considerable magnitude. As compared with the Earth their diameters may be approximately stated as follows:—That of the first rather less than $\frac{1}{4}$, of the second $\frac{1}{4}$, of the third $\frac{1}{3}$, and of the fourth rather more than $\frac{1}{3}$. The third is about the size of Mars. These four moons must present to the inhabitants of Jupiter a spectacle of endless variety.

Although their orbits are doubtless elliptical, the eccentricities of the first and second are so small as to be insensible to observation. That of the third is sufficiently sensible; and that of the fourth still greater, but subject to considerable variations. The direction of the motions of the satellites in their orbits is from west to east, according to the general analogy of the planetary system; and from observed periodical defalcations of light to which they are subject, it has been inferred that, like our own moon, each of them revolves about its axis in the same time as that in which it completes a sidereal revolution about the planet.

From the preceding table it will be seen that the periodic time of the first satellite is nearly half of that of the second, and that of the second nearly half of that of the third. The mean angular motions of these three satellites, therefore, form very nearly the progression 1, $\frac{1}{2}$, $\frac{1}{4}$; so that the mean motion of the first satellite, added to twice that of the third, is very nearly equal to three times the mean motion of the second. Another equally singular analogy is, that the mean longitude of the first, *minus* three times that of the second, *plus* twice that of the third, is always very nearly equal to two right angles. These two results subsist equally in respect both of the sidereal and synodical motions and longitudes; and it follows as a consequence of the last, that for a great number of years at least, the three first satellites cannot be eclipsed at the same time, for in the simultaneous eclipses of the second and third the first will always be in conjunction with Jupiter, and *vice versa*.

On account of the shortness of the periods of revolution, the eclipses of the satellites (especially of the first) take place very frequently; and they are phenomena of considerable importance in astronomy, from their affording signals by means of which the differences of terrestrial longitudes are determined, in the same manner as in the case of an eclipse of the moon. The method, however, is not capable of the same precision as is afforded by lunar observations.

The eclipses of Jupiter's satellites have also an historical interest, from having led Rœmer to the important discovery of the successive propagation and velocity of light. When Jupiter is in opposition with the sun, and his distance from the earth consequently *less* than his distance from the sun by the whole radius of the earth's orbit, the eclipses are observed to happen about 16 m. 26 sec. earlier than they happen when the planet is in conjunction, and its distance from the earth *greater* than its distance from the sun by the same quantity. This phenomenon can only be explained by supposing that light occupies 16 m. 26 sec. in traversing the earth's orbit, and consequently 8 m. 13 sec. in coming from the sun to the earth, which gives a velocity of about 192,000 miles in a second. The theory, with its consequences, has been amply confirmed by Bradley's discovery of the aberration. *See* ABERRATION.

Satellites of Saturn. — Saturn, as already mentioned, is accompanied by seven satellites. The most distant, which is by far the largest, was discovered by Huygens in 1665. Four others were first seen by Dominic Cassini about twenty years afterwards; but the two interior ones, which can only be seen under very peculiar circumstances, and with the aid of the most powerful telescopes, were discovered by Sir William Herschel, in 1789. On account of the difficulty of observing the satellites of this planet, their theory has been little studied. The third law of Kepler, which connects the periods and distances, is found to be preserved, as in the system of Jupiter. The planes of their orbits coincide nearly with that of the ring, with the exception of the seventh, which makes an angle with that plane of about 3 or 4 degrees. The orbit of this last is sensibly elliptical, the eccentricity being ·049. Owing to the obliquity of the orbits to Saturn's ecliptic, the satellites are not eclipsed in every revolution, but (with the exception of the two interior ones) only fall into the shadow of the planet at the times when the ring is seen from the earth nearly edgewise. The following table shows their mean distances from Saturn in terms of the equatorial radius of the planet, and their periods of sidereal revolution:—

Satellite.	Mean Distance.	Periodic Time.		
		d.	*h.*	*m.*
1	3·351	0	22	38
2	4·300	1	8	53
3	5·284	1	21	18
4	6·819	2	17	45
5	9·524	4	12	25
6	22·081	15	22	41
7	64·359	79	7	55

The two interior satellites appear to just skirt the exterior edge of the ring. The seventh, like the satellites of Jupiter, exhibits periodical changes in the intensity of

its light, whence it is inferred that it revolves on its axis in the same time in which it completes its orbital revolution.

Satellites of Uranus. — Sir John Herschel remarks, that with the exception of the two interior satellites of Saturn, the attendants of Uranus are the most difficult objects to obtain a sight of, of any in our system. Their existence was first discovered by Sir William Herschel, who suspected their number to be six; but he was only able to obtain micrometrical measures of the distance of two of them, and only those two have yet been seen by any other astronomer. Sir W. Herschel's observations are given in the *Phil. Trans.* for 1788 and 1797, and again in the vol. for 1815. They were made between the years 1787 and 1798; and from the latter period until 1828, the planet having been unfavourably situated, these satellites remained unobserved, and had even fallen out of notice. Between the latter year and 1834 a series of observations, recorded in the *Memoirs of the R. Astr. Society*, vol. viii., were made by Sir John Herschel for the purpose of verifying his father's results, which, with respect to two satellites, were confirmed in the amplest manner. The periodic times deduced from his observations are respectively 8 d. 16 h. 56 m. 31·3 sec., and 13 d. 11 h. 7 m. 12·6 sec. The orbits are nearly circular, and almost perpendicular to the ecliptic, being inclined to that plane in an angle of $78^{\circ} 58'$; and what is extremely remarkable, as contrary to the otherwise unbroken analogy of the solar system, the motions of the satellites in their orbits are *retrograde*, or from east to west. The following table shows the distances (in radii of Uranus) and periods of all the satellites, according to Sir William Herschel. (*Herschel's Astronomy*, *Cab. Encyc.*)

	Mean Distance.	Sidereal Period.			
		d.	*h.*	*m.*	*s.*
1?	13·120	5	21	25	0
2	17·022	8	16	56	5
3?	19·845	10	23	4	0
4	22·752	13	11	8	59
5?	45 507	33	1	48	0
6?	91·008	107	16	40	0

SATIN. A closely woven silk, generally dressed with gum, especially when intended for ribands, dresses, &c.

SATIN SPAR. A fibrous variety of carbonate of lime assuming a silky appearance when polished.

SATIRE, in Literature, has been defined a representation of vice, or of the ridiculous, either in the form of discourse or put in dramatic action. The word satire must not be confounded as to its etymology with the satyri of the Greeks, which were burlesque dramatic pieces, in which the persons represented a band of satyrs. (*See* DRAMA.) The modern word satire, Latin satira, is derived from the *lanx satura*, — a dish full of various fruits and herbs which was carried in procession at the feasts of Ceres. Whence the word came to signify a poem full of miscellaneous matter without orderly method; and in this sense only it was probably employed by Lucilius, the first writer of satires: although the title so usurped by him was afterwards only applied to poems of a similar character with his own, viz. containing moral reflection, interspersed with critical touches directed against real or imaginary personages.

Satire, in the literary sense of the word, as designating a species of composition, is usually confined to a species of poetry; but prose works, of which the contents are of a satirical character, are often comprehended under the same appellation. Dramatic writings, also, are not satires in the stricter sense of the word, although their contents be of a satirical character. According to their subjects, satires are divided into political and moral; and these again severally subdivided into personal and general. Political satires, in almost every language, have been nearly confined to prose; the moral satire alone has found its appropriate vehicle in verse. The only Greek satirist, of whom any fragments have reached us, was Archilochus; and his attacks were evidently directed against individuals. Aristophanes possessed a vein of satirical power, both in the indignant and ludicrous strain, which has never been surpassed; and his dramas contain not only sarcasms on individuals, but also political and ethical lessons of the highest value. But the moral satire, properly so called, was invented by the Romans, not only in form, but in substance also, and by them carried to perfection; and it is remarkable that the only species of Roman poetry which has any degree of originality, is that which would seem to have accorded the least with the grave and austere turn of the genuine Roman character.

Of the three Roman satirists whose works have reached us, Horace, the earliest, excels in conveying moral and prudential lessons in beautiful and precise language, in light allusions to the follies or excesses of his time; sometimes, though rarely, assuming the comic character, but generally evincing more of the indefinable quality termed by us humour, than is shown by any other classical writer, with the exception of Aristophanes. Whether the various personages introduced by Horace, for the most part rather as examples to be shunned than as individuals to be held up to laughter or contempt, were intended to represent to his readers, by allusions now undiscernible, actual characters known to them, is a matter not easily ascertainable. The same may be said with respect to Juvenal, whose selected victims are for the most part exalted or notorious personages of the generations immediately preceding his own; and it is not ascertained, although it has often been conjectured, that their names were intended to conceal those of cotemporaries of his own. Juvenal, without either wit or humour, excels in the deep tones of moral indignation befitting the scandalous excesses of the times in which he lived: his exalted notions of virtue, and even of sanctity, are so far superior to the ordinary standard of moral excellence to be drawn from classical writers, that it has been conjectured that he, as well as Persius, had made some acquaintance, either directly or indirectly, with the lessons of Christianity. Persius, although he occasionally rises into very elevated flights of poetry, does not afford many examples of the peculiar excellences of the satirist.

In the literature of the modern nations, the fate of satire has been similar to that which has befallen many other species of composition. The name and form of the ancient satire have been preserved by many writers, who have produced, for the most part, little besides cold or exaggerated imitations of antiquity. But the true spirit of satire, in its moral beauty, its humour, and its delicate irony, has been inherited by others, who had too much originality of thought to tie down their genius to an antiquated form of writing. Thus in France, Boileau is or was generally cited as the prince of satirists: his satires are closely formed on the model of Horace, and are elegant and correct in style. Besides him, Regnier and many other writers have adopted the same line. But the true satirists of France are Rabelais, in his inimitable romances; Montaigne the essayist, endowed with much of the delicate and harmless sarcasm of Horace; and, in later times, Voltaire. So in England, although we possess satirists of considerable merit, who have adopted the form of the ancient satire, our true national satirists are to be found among our essayists and novel-writers. Bishop Hall, in the reign of Elizabeth, and Donne, in that of James, published collections of satires, directed partly against the actual follies or vices of their times, but too closely paraphrased, for the most part, from the Latin, to admit of much original observation. Withers, among our early satirists, is the only other writer who is at all remembered. Among our modern poets, Pope founded his satires on the model of those of Horace, and of some of his English predecessors. His style and train of thought were rather French than Roman. His works of this description are, in point of form, mere imitations; but they are admirable for their point and the beauty of the verse, and not unfrequently contain pungent personal allusions, without which, unfortunately, a professed satirist can attract little notice and produce little effect. Johnson in his two well-known imitations of Juvenal, Churchill, and Young, are the latest writers of any note who have composed in the form of the ancient satire. But of all these writers, not one possesses a genuine or national character, except perhaps Churchill; while Swift, Fielding, &c., are, in our literature, what Horace and Juvenal were in those of the Romans, — the painters of existing manners, and the representatives of public opinion respecting them. The literary satire may, perhaps, be mentioned as a separate species of composition, containing either rules of writing, or critical observations on the defects of individual writers. Some of Horace's satires and epistles (as well as his *Ars Poetica*) belong exclusively, others partially, to this class; and have given birth to a series of similar productions, down to the *English Bards and Scotch Reviewers* of Lord Byron. (See as to the Roman satire, *Quart. Rev.* vol. lii.; *Mem. de l'Ac. des Inscr.* vol. xxxix.)

SA'TRAP. The title given by the Greek writers to the governors of provinces under the Persian kings before the conquests of Alexander. The satrapies of that empire are enumerated by Herodotus. The name is thought by some to be derived from a Persian word, signifying "fixed star." (*Mem. de l'Ac. des Inscr.* vol. xxxi.)

SA'TURDAY. The seventh day of the week, held by the Jews as their sabbath. It was dedicated by the Romans to Saturn; whence its name.

SA'TURN. An Italian deity having many points of similarity with the Grecian Kronos (Κρονος), with whom he is accordingly frequently identified. He seems to have been originally the god of earth (of which his wife Tellus, Ops, or Rhea was the goddess), and presided over tillage, of which the sickle he carried was the symbol. The treasury at Rome was in his temple.

The Grecian Kronos was the youngest son of Heaven and Earth, and the father of Jupiter, Juno, Neptune, and

Pluto. He usurped the sovereignty, and was in his turn deposed and imprisoned by Jupiter. His reign was celebrated by the ancient poets as the golden age.

The whole history of this deity is probably allegorical. The name itself with a slight variation signifies time (χρόνος); and his attribute of the sickle, together with the account of his being the son of Heaven, by whose luminaries time is measured, and the husband of Rhea (flowing), and of his devouring his own progeny, are corroborative of this conjecture.

Niebuhr regards Saturn and Ops as the god and goddess of the earth, its vivifying and its receptively-productive powers. (*Rom. Hist.* vol. i. p. 66., Cambr. transl.) Creuzer makes Saturn the great god of nature, in many respects assimilated to Janus. He is the god who suffices for himself, — the god who is satisfied with his own powers. (*Symbolik*, par Guigniaut, vol. iii. p. 499.) Hence the derivation of the name from the Latin satur, *full, satisfied*.

SATURN. One of the principal planets in the solar system, and the ninth in the order of distance from the sun. Though less brilliant than Venus and Jupiter, Saturn is still a conspicuous object in the heavens, and has accordingly attracted the attention of astronomers since the first dawn of the science.

Saturn revolves at the distance of about 890 millions of miles from the sun, the mean radius of his orbit being 9·538786 times that of the earth's orbit; and the period of his sidereal revolution is 10759·2198174 mean solar days, or about 29½ years. The orbit is nearly circular, its eccentricity being only ·0561505 (half the major axis being unity); and it is inclined to the ecliptic in an angle which, at the beginning of the present century, was 2° 29′ 35″·7, and is subject to a decrease of 0·155″ annually.

The diameter of Saturn at his mean distance from the earth subtends an angle of about 16·2″; whence his true diameter is 9·982 times that of the earth, or about 76068 miles, and consequently his volume is nearly a thousand times that of the earth. From the theory of his perturbations, his mass compared with that of the sun is found to be ·000284738; whence his density is inferred to be to that of the sun as 55 to 100, or about ⅛th of the density of the earth.

From the observation of certain dark spots on his surface, Saturn is found to revolve about an axis in 10 hours 29 m. 16·8 sec. This rapid rotation of so large a body gives rise to a great centrifugal force at the equator of the planet, and accordingly his form is that of a spheroid considerably flattened at the poles, the ratio of the polar to the equatorial diameter being nearly that of 11 to 12. The inclination of his equator to the plane of the ecliptic is 31° 19′, or nearly 28° 49′ to the plane of his orbit.

When seen through a good telescope, the disc of Saturn appears striped with dark belts, somewhat similar, but broader and less strongly marked than those of Jupiter. From their parallelism to his equator, it is inferred that they subsist in his atmosphere, and are probably determined by currents similar to our trade winds.

Saturn is attended by seven satellites; but the two nearest the planet can only be seen in certain favourable circumstances, and with telescopes of the very highest power. *See* SATELLITE.

Saturn's Rings. — Saturn presents a phenomenon to which there is nothing analogous in the rest of the solar system. This consists of two flat, broad, and very thin rings, both lying in the same plane, and concentric with each other and with the planet. They are separated from the body of the planet by an interval equal to about two and a half times the diameter of the earth, and from each other by a much smaller interval. The plane in which they lie is inclined to the ecliptic in an angle of 28° 40′; and hence they present themselves obliquely to the earth, under the form of an ellipse, the breadth of which, when greatest, is nearly equal to half the length. The following are the dimensions of this extraordinary appendage, as given by Sir John Herschel (*Treatise of Astronomy*, *Cab. Cycl.*), from the micrometrical observations of Struve, with the exception of the thickness of the rings, which was deduced from his own observations: —

	Miles.
Exterior diameter of exterior ring - -	= 176418
Interior diameter of exterior ring - -	= 155272
Exterior diameter of interior ring - -	= 151690
Interior diameter of interior ring - -	= 117339
Equatorial diameter of the planet - -	= 79160
Interval between the planet and interior ring	= 19090
Interval of the rings - -	= 1791
Thickness of the rings not exceeding -	= 100

As the plane of this double ring maintains its parallelism during the revolution of the planet, the angle under which it is presented to the sun is continually changing, and hence the varieties which take place in its apparent form and magnitude. The points in which it intersects the ecliptic are in 170° and 350° of longitude; consequently, whenever the planet comes into either of those longitudes (and it must pass through both in each revolution), the plane of the ring passes through the sun, and only the thin edge is illuminated. In this case, the whole quantity of light which is reflected from it is insufficient to render it visible, and it entirely disappears, even in the most powerful telescopes. On the 29th April, 1833, Sir John Herschel records, "The disappearance of the rings is complete, when observed with a reflector 18 inches in aperture and 20 feet in focal length." A little before or after the planet is in this position, the ring is seen as a fine straight line of light drawn across the disc of the planet, and projecting on each side like *ansæ* or handles. As the planet continues to recede, the sun's rays fall upon the ring more obliquely, and the luminous line gradually opens out into an ellipse, which becomes wider and wider until it attains its maximum, when the longitude of Saturn is 80° or 260°. In following out these phenomena, it is, however, necessary to take into account the position of the earth relatively to the sun and the plane of the ring; for it is evident, in the first place, that the ring will only be visible when the sun and earth are both on the same side of it; and, in the second place, that it will become invisible when its plane passes through the centre of the earth, as none of the light reflected from its sides can then reach us. On this account the disappearance of the ring is generally double, the earth passing twice through its plane in the same revolution. The successive disappearances of the ring form a period of about 15 years, or half the times of Saturn's revolution in his orbit. At present (1840), the north side of the ring is illuminated; in December, 1847, it will be invisible; and in April, 1855, the south side will become visible. The two sides of the ring have thus alternately fifteen of our years of sunshine, and fifteen years of darkness.

The singularity of Saturn's appearance was first noticed by Galileo, to whom the planet appeared *triple*, or as a large body placed between two small ones. The explanation of the phenomena by means of the ring was first given by Huygens. Some astronomers have thought they observed numerous dark divisions in the ring; so that instead of two there must be a number of concentric rings. Struve states, that he could perceive no traces of such division in the great Dorpat refractor.

That the ring is composed of solid ponderous materials is proved from the circumstances of its casting a dark shadow on Saturn on the side nearest the sun, and receiving the shadow of the planet on the opposite side. The ring must therefore be under the influence of the planet's attraction, and also liable to be deranged by the disturbing action of the satellites, the largest of which does not move in the same plane. Hence it is an interesting problem in physical astronomy to determine the conditions under which its equilibrium is maintained. Laplace has shown, from the theory of gravitation, that in order to maintain the stability of the ring, it is necessary that the planet's attraction be counteracted by a centrifugal force arising from a very rapid rotation of the ring in its own plane. Observation has confirmed the result of theory; for from the motions of certain dusky spots on its surface it has been found that the ring revolves in 10 hours 29 m. 17 s., which is very nearly the period assigned by Laplace, and that in which a satellite would revolve at a distance equal to that of the middle of the ring. Laplace also showed that in order to resist the tendency to subversion of the equilibrium, it is necessary to suppose the ring to be of unequal density or thickness in its different parts, so that the centre of gravity may not coincide with the centre of figure; for if it were perfectly similar throughout, its equilibrium would be disturbed by the slightest force, as the attraction of a satellite; and as it would have no tendency to recover itself, it would ultimately be precipitated on the planet. This inequality of form would seem to be indicated by observation, for it has been noticed that the two arms of the ring sometimes appear to be dissimilar. According to Bessel, the mass of the ring is equal to about the 1-118th part of that of the planet. For further information, see *Herschel's Treatise on Astronomy*.

SATURNA'LIA, the festival of Saturn, was celebrated at Rome about the middle of December, and occupied at different times one, three, and five days. It was a season of complete liberty and rejoicing. No business was done: friends visited and made presents to each other; and, what was most remarkable, slaves were permitted to jest with their masters, and were even waited on at table by them.

SA'TYRS. In Classical Mythology, divinities, or rather supernatural personages, represented with the heads, arms, and bodies of men, and the lower parts of goats. They were under the peculiar government of the god Bacchus. Some antiquaries have fancied that the notion of satyrs arose from the introduction of ourang-outangs by the real Bacchus, on his return from his conquest of India, and derive the name from the Heb. sahurim, *hairy men;* Bacchus, according to tradition, having remained some time in Palestine during his return. In the same

way we may perhaps account for St. Augustin's story, of a satyr having been seen and caught in his own time in the deserts of Africa. In Grecian Dramatic Literature, the name satyr is applied to a theatrical piece, in which the chorus consisted of satyrs: of a semi-burlesque character, to judge of it by the only specimen left to us, the *Cyclops* of Euripides. It was customary for the tragedian to present at the same time three tragic pieces and one satyr, forming a tetralogy. In Zoology, the ourang-outang (*Simia satyrus*, Linn.) is sometimes called satyr.

SAUCISSON. In Fortification, a long pipe or bag filled with gunpowder for the purpose of firing a mine. The term is also applied to a fascine, longer than the common ones, used for raising batteries and repairing breaches.

SAU'NDERS or SANDAL WOOD. The white or scented sandal wood is the produce of the *Santalum album*. It is brought from the East Indies. When distilled with water it yields a thick essential oil, smelling something like roses. Red saunders or sandal is the wood of the *Pterocarpus santalinus*, also a native of India. Its colouring matter is insoluble in water, but soluble in alcohol, and is used to impart a red tinge to certain tinctures. The resinous exudation of this tree constitutes one of the varieties of *dragon's blood*.

SA'URIANS, *Sauria*. (Gr. σαυρος, *a lizard*.) The name of an order of reptiles, including all those which are covered with scales and have four legs, as the crocodile and lizard. The mouth of the saurians is always armed with teeth, and their toes are generally furnished with claws; they have all a tail more or less long, and generally very thick at the base. A few species, exceptions to the general character, have only two legs. The most gigantic and singular species of the Saurian order are now extinct.

SAUSSURITE. A variety of nephrite named in honour of Saussure, who discovered it on the banks of the lake of Geneva in rounded masses.

SAVA'NNAHS. The name given to those vast systems of plains watered by the Missouri and Mississippi. These savannahs are greatly diversified in appearance; but they have some general features, which the reader will find systematically described in Mr. Flint's work on America.

SAVINGS BANKS. *See* BANK, SAVINGS. (See also Dégerando, *De la Bienfaisance Publique*, vol. iii. l. 2. ch. 4.)

SAXIFRAGA'CEÆ. (Saxifraga, one of the genera.) A natural order of herbaceous Exogens, chiefly inhabiting the mountainous regions of Europe and the northern parts of the world. They are nearly allied to *Rosaceæ*, from which they differ in having polyspermous, didymous, partially concrete carpels, and albuminous seeds, and in wanting stipules. The root of *Heuchera Americana* is a powerful astringent, whence it is called in North America alum root; other species are pretty herbaceous plants: none of them are of general interest.

SAXON ARCHITECTURE. *See* ARCHITECTURE.

SAXON BLUE. A solution of indigo in concentrated sulphuric acid: it is much used as a dye stuff.

SCABI'NUS. The Latinized form of the old German word schoppe, in French échevin. Judicial officers of various descriptions in the middle ages bore this title, especially in the "communes," or municipalities. See as to its history, *Meyer's Instit. Judiciaires; Mem. de l'Ac. des Inscr.* vol. xxxvii.

SCA'BROUS. (Lat. scaber, *rough*.) In Zoology, when a surface is rough to the touch, from granules scarcely visible.

SCA'FFOLDING, in Architecture, is the temporary combination of timber-work, by the means of upright poles and horizontal pieces, on which latter are laid the boards for carrying up the different stages or floors of a building, and which are *struck* or removed as soon as they have answered their purpose. The scaffolding used for carrying up buildings on the Continent has always been more scientifically and solidly constructed than that used in this country. But great improvements have latterly taken place; and there seems to be a prevalent notion here, in the present day, that for large buildings a little more skill should be displayed than that which emanates from the combination of uninstructed Irish labourers.

SCAGLIO'LA. (It.) In Architecture, a composition; sometimes called also *Mischia*, from the mixture of colours employed in it, being made to imitate marble. The Florentines claim the invention of this art, but it had been practised in Lombardy previous to its introduction at Florence. Lanza says that it was invented by Guido Sassi, who died at the age of 65, in 1649, at Carpi, in the state of Modena, and that he commenced by executing cornices and other members of architecture which had all the appearance of the finest marbles; whereas its introduction at Florence was not till the middle of the 18th century. Scagliola is composed of gypsum or sulphate of lime, calcined and reduced to a fine powder, with the addition of which to water a fine paste is made. When columns are made with this composition, a frame or cradle is first formed, which is lathed round, and coated with lime and hair, raised up in some parts with small projections. On this, when dry, is laid a composition consisting of pure gypsum, calcined and passed through a sieve, and, as wanted, mixed with glue or isinglass; it is floated with wooden moulds of the proper form, during which operation the colours, by which the imitation is obtained, are put on. When this is set the work is smoothed with pumice-stone with one hand of the workman, while the other is employed in washing it with a sponge and water. It is then polished with tripoli, charcoal, and a piece of fine linen, and afterwards with a piece of felt dipped in oil and tripoli, and finished off with pure oil laid on with cotton wool.

SCALD (*Skâlld*), signifies in the ancient Norsk language a poet. In the old northern literature, those mythological poems of which the writers are known are properly called songs of the Scalds, while those of unknown authors are termed Eddas. It appears from Tacitus that the ancient Germans had those three classes of poems which were found at a later era in Scandinavia, namely, relating to the gods, to heaven, and to historical subjects. The Scalds whose remains have come down to us are very numerous. Their poems are partly alliterative, and partly rhymed; and this latter circumstance seems to indicate works of comparatively recent date. The historical value of their poems is considerable; but they are written in a peculiar vein of exaggeration, and in a metaphysical and almost enigmatical fashion, which appears to have been characteristic of the poetical art of the north. (*See* EDDA, SAGA.) The most complete list of the Scalds, and commentary on Scaldic poetry, is to be found (according to the *Conversations Lex.*) in the *Fundgruben des Orient.* vol. i.

SCALE. (It. scala, *a ladder*, or *series of stairs*.) In Music, a progressive series of sounds rising in acuteness or falling in gravity from any given pitch to the greatest practicable distance, through such intermediate degrees as create an agreeable and perfect succession, wherein all the harmonical intervals are conveniently divided. See the words DIATONIC and CHROMATIC.

SCALE. In Mensuration, a line or rule of a definite length, divided into a given number of equal parts, and used for the purpose of measuring other linear magnitudes. It becomes a *standard scale* when all its divisions have been examined and compared with some *standard measure*. (*See* MEASURE.) The scales of thermometers are graduated from some arbitrary point or zero (as that which indicates the temperature of freezing water), from which the heat is counted upwards or downwards in degrees, which are also arbitrary.

The term *scale* is also applied to a mathematical instrument, consisting of an assemblage of lines and figures engraved on a plane rule, by means of which certain proportional quantities or arithmetical results are obtained by inspection. Of these the principal are the *plane scale*, the *diagonal scale*, *Gunter's scale*, &c. For the construction and uses of these various scales, see *Robertson's Description and Use of Mathematical Instruments*.

In Arithmetic, *scale* signifies the order of progression on which any system of notation is founded; as the *binary* scale, the *denary* scale, &c. *See* BINARY ARITHMETIC, NOTATION.

SCALE, in Zoology, is properly applied to the plates, generally thin, small, and umbricated, which defend the skin of fishes. They are substances of different texture which are developed beneath the true epiderm, and appertain to the system of the rete mucosum. The so-called scales of serpents and other reptiles are modifications of the epidermis, and are sometimes termed "scutes." Fishes have been classified according to the structure of their scales. See the words CTENOID, CYCLOID, GANOID, PLACOID.

SCALE'NE. (Gr. σκαληνος.) In Geometry, a scalene triangle is a triangle of which the three sides are unequal. A cone or cylinder is also said to be scalene if its axis is inclined to its base; but in this case the term *oblique* is more frequently used.

SCALE'NUS. A muscle of the neck, situated between the transverse processes of the cervical vertebræ and the upper part of the neck.

SCALPEL. (Lat. scalpare, *to carve*.) A dissecting knife.

SCALPRUM. (Lat. *a knife*.) In Mammalogy, the cutting edge of the incisor teeth.

SCA'MMONY, in Pharmacy, is the gum-resin of the *Convolvulus scammonea*, chiefly imported from Aleppo and Smyrna in packages, called *drums*, weighing about 100 pounds each. It is of a dark olive colour, and when wetted and rubbed should easily form a milky solution: it is very apt to be adulterated, and an article entirely fictitious is often sold under the name of scammony. Scammony is an excellent drastic purge, and is generally administered in combination with other purgatives in doses of three or four grains.

SCA'NDALUM MAGNA'TUM. In Law, an action

which still lies, although for a long period it has never been resorted to, on the stat. 2 Ric. 2. stat. 1. c. 5., and statute of Westminster the First, 3 E. 1. c. 34., for words spoken in derogation of a peer, a judge, or other great officer of the realm; which need not be such as would be actionable at common law in the case of a private person. "The Duke of Richmond v. Castellow," in the eighth year of Queen Anne, seems to have been the last instance of this species of action.

SCANSO'RIALS, *Scansores*. (Lat. scando, *I climb*.) Climbing birds. The name of an order of birds, including those which have the toes arranged in pairs, two before and two behind; a conformation of the foot which is admirably adapted for the act of climbing.

SCANT. In Naval language, the term applied to the wind when it is barely fair.

SCANTLING. (Fr. echantillon.) In Architecture, the measures of breadth and thickness of a piece of timber or other material. It is also the name of a piece of timber when under five inches square.

SCANTLING. In Naval Architecture, the scale or dimensions of the breadth and thickness of the timbers. Thus two ships of different sizes may have the same scantling.

SCA'PE. In Botany, a peduncle, which, in plants destitute of a stem, rises above the ground and supports the flowers upon its apex, as in cowslip. Also a synonym of *Scapellus*.

SCAPEMENT, or ESCAPEMENT. *See* HOROLOGY.

SCAPHITE. (Gr. σκαφη, *a boat*.) A genus of elliptical-chambered shells, belonging to the family of Ammonites, having the inner extremity coiled up in whorls embracing one another, and the outer extremity continued nearly in a horizontal plane, and then folded back, so as sometimes to touch the spire of the opposite end of the shell. The transverse plates are numerous, and are pierced by a marginal siphuncle at the back of the shell, and their edges are deeply cut and foliated. These beautiful shells, which thus resemble the ancient form of a boat, are almost peculiar to the chalk formation.

SCA'POLITE. A mineral, originally from Arendahl in Norway, the crystals of which are often collected in groups of parallel, diverging, or intermingled prisms; hence its name, from σκαπος, *a rod*, and λιθος, *a stone*.

SCA'PULA. (Lat. *the shoulder*.) In Comparative Anatomy, the bone which passes from the shoulder joint in a direction towards the vertebral column. It is broad and flat, generally triangular, sometimes subquadrilateral, in the Mammalia; narrow, and commonly sabre-shaped, in birds; narrow and straight in Saurian reptiles; a round, strong, and straight column, in Chelonian reptiles; variously shaped, and articulated to the back of the skull in most fishes.

SCA'PULARS, or SCAPULAR FEATHERS, in Ornithology, are those which take their origin from the shoulders and cover the sides of the back.

SCA'PULARY. A portion of the dress of the monastic orders, consisting of two bands of woollen stuff, of which the one crosses the back or shoulders, and the other the stomach. According to the Abbé Fleury (*Mœurs des Chretiens*), the scapulary originated with St. Benedict, and was a large and heavy covering of the shoulders, worn by the early monks in their rural labours for the convenience of carrying loads, and to protect the tunic. Simon Stock, an Englishman, general of the Carmelites in the 13th century, first introduced, under the authority of a vision, the notion that the scapulary is an especial sign of devotion to the Virgin Mary. Since that time it has been not an uncommon superstition that whoever dies wearing it is sure of salvation. The scapulary of lay persons consists of two little pieces of stuff on which the name of the Virgin is embroidered.

SCA'PUS. (Lat. *a stalk*.) In Ornithology, the stem or trunk of a feather, including the hollow base or quill, "calamus," which is inserted into the skin, and the solid exserted stem supporting the barbs, or "rachis."

SCAPUS. In Architecture, the same as the *shaft* of a column, which see.

SCARABÆ'IDANS, *Scarabeidæ*. (Lat. scarabæus, *a beetle*.) The name of a family of Coleopterous insects, of which the genus *Scarabæus* is the type; it corresponds with the great tribe of *Lamellicorns*. See that word.

SCARABÆ'US. In Antiquities. The use and meaning of the scarabæus, as a symbol, are, as yet, among the mysteries of archæological science. The Egyptians, it is said, found in it an emblem of the world instinct with the seeds of life; because the kind of beetle represented by it forms a ball of earth in which to deposit its eggs. It is also called a type of the sun. However this may be, it was habitually worn by the ancient Egyptians and Etrurians as an amulet. According to Mrs. Hamilton Gray (*Tour to the Sepulchres of Etruria*, 1840), several different styles of the scarabæus are traceable. The ancient Egyptian scarabæus was plain, or inscribed with characters; and was made of opaque stone, basalt, or porphyry. The Etrurian scarabæus (found in quantities in the sepulchres) was of semitransparent stone, cornelian, onyx, sardonyx, agate, or jasper. It is almost always engraved, generally with the figure of a god or genius, supposed to be the chosen protector of the individual who wore it: sometimes with whole scenes, such as the labours of Hercules, races, &c.; sometimes with Etruscan words or names; and occasionally with Egyptian divinities, — Isis or Horus. Lastly, the modern Egyptian scarabæus of Roman times was generally of precious or semi-precious stones, and rudely engraved; and seems to belong to an age when the religious use of the scarabæus was forgotten, and it was retained only as an ornament. In the Etruscan scarabæi themselves, according to the same authoress, there are three distinct styles of art remarkable, — the rude or native Etruscan, the Grecian, and that of a period of decline.

SCA'RAMOUCH. (Ital. scaramuccia, *skirmish*.) A personage in the old Italian Comedia dell' Arte, dressed in the Spanish or Hispano-Neapolitan costume, and representing a military personage, a poltroon and braggadocio, who always ended by receiving a beating from the hands of Harlequin. The most celebrated Scaramouch of the Italian theatre at Paris was Tiberio Flurelli, a Neapolitan, who had the honour of making Louis XIV. laugh when an infant; and whose agility was such that he was able, according to his biographers, to give a box on the ear with his foot at the age of 80.

SCARFING. In Architecture, the formation of a beam out of two pieces of timber; usually employed when it cannot be conveniently procured in one length. It is usually performed by indenting the pieces where they are joined to each other, and bolting them together in the opposite direction.

SCARFSKIN. The cuticle or epidermis. *See* SKIN.

SCARIFICA'TOR. An instrument used in cupping; it consists of 10 or 12 lancets, which are discharged through apertures in its plane surface by pulling a kind of trigger, so that in passing they make a number of incisions in the part to which the instrument is applied.

SCARLATI'NA, or SCARLET FEVER. This highly contagious disease assumes two forms. In the one it comes on with the usual symptoms of fever, such as languor, chills and heat, thirst, nausea and vomiting; and on the third or fourth day a scarlet efflorescence appears upon the skin, which in three or four days ends in the cuticle peeling off in branny scales: the febrile symptoms and soreness of the throat, if any had been observed, then give way, and the patient gradually recovers. It is, however, not uncommonly followed by dropsical swelling of the body, which is but of short continuance. In the other form of this disease the febrile symptoms are at first more alarming: there is bilious vomiting, great soreness and ulceration of the throat, quick and small pulse, laborious breathing; and the eruption, instead of mitigating the symptoms, is accompanied by their dangerous increase. The body becomes swollen, and the nose and eyes inflamed; the breath grows fœtid, and the inflammation of the throat terminates in greyish sloughs, which give it a speckled appearance. Under an aggravation of such symptoms, the patient is cut off; or his recovery is very slow, and dropsical swellings and glandular tumours follow, and leave him in a very precarious state. It occasionally happens that the putrid symptoms run very high; the rash is livid, and accompanied by petechiæ; the breath highly fœtid, the throat gangrenous; and other symptoms announce a highly malignant form of the disease.

In the milder form of scarlet fever, the bowels should be cleansed by saline aperients, and the patient kept in a moderate temperature, as near 60° as possible, and in a clean and open room. If the throat is much affected, an emetic should be given as early as possible, and the bowels opened by small doses of calomel and antimonials. When the heat of the body is much above the usual standard, or very distressing, sponging with cold water, judiciously resorted to, has proved eminently useful. Acidulated gargles must be used for the throat; and the dilute acids, with light preparations of bark and tonics, at the decline of the eruption, are required. Where the malignant symptoms run high, cordial tonics, acids, wine, and the other treatment of putrid fevers must be adopted.

Scarlet fever is distinguished from measles by the greater extent and want of elevation of the eruption, and by its not congregating into semilunar patches; nor is there the cough, and running from the eyes and nose, which usher in the measles. It seizes those of all ages, but children and young persons are most subject to it; and it appears at all seasons of the year, but in autumn is often epidemic. It may attack the same person more than once.

SCARP. In Fortification, the interior slope of the ditch. *See* ESCARP.

SCE'LIDES. (Gr. σκελος, *a leg*.) In Mammalogy, the lower, posterior, or pelvic extremities.

SCENE. In Dramatic Literature (from the Gr. σκηνη, *arbour*), dramatic representations, having, it is supposed, originally taken place on spots of ground shaded with boughs of trees. The imaginary place in which the ac-

tion of the play is supposed to pass; also a division of a drama: properly speaking, whenever the action changes to a new scene or place. But in the French theatre, and those framed on its model (in which unity of place is observed), every entry of an actor constitutes a new scene. On the English stage, the subdivision called a scene is extremely arbitrary; the scenes in most plays being far more numerous than the actual changes of scene, while at the same time the French rule is not observed, and actors enter in the middle of a scene. The scenes in a play are numbered as subdivisions of the act. *See* ACT.

SCENE PAINTING. A department of the art of painting governed by the laws of perspective, applied to the peculiar exigencies of a theatre. It is conducted chiefly in water colours, and admits of the most striking effects, which indeed, in scene painting, is almost all that is required.

SCENERY. The appearance of a place or of objects, or the representation of a spot wherein an action is performed. *See* LANDSCAPE.

SCE'PTICISM. (Gr. *σκεπτομαι, I examine.*) In the History of Philosophy, a name given to that tendency of thought or system of doctrines the object of which is, by denying the existence of all grounds of knowledge, to introduce universal doubt and suspension of assent. Schools of scepticism have existed at several different periods in the progress of philosophical inquiry. The first who received or adopted the name was Pyrrho, a contemporary of Alexander the Great, and his successors, who taught in Athens about the year 300 B.C. Our chief notices of his opinions are derived from the writings, in verse, of his disciple Timon, preserved to us by Sextus Empiricus. He was led to his sceptical views partly by the contradictions observable in the impressions on our senses, and partly by the incompatibility of the principles of different schools with each other. To a complete suspension of judgment in speculation (*ἐποχή*) he united a corresponding state of indifference in feeling (*ἀταραξία*), and made virtue and happiness to consist in the absence of mental perturbation. Either he or his scholars endeavoured to present a synopsis of their sceptical views in ten general forms, or commonplaces, all of which, however, may be included in one or other of the two sources of doubt mentioned above.

The school of Pyrrho seems to have expired with his disciple Timon; though many of his views were espoused and maintained by the later academy. (*See* ACADEMICS.) About the middle of the third century of the Christian era, we meet with a school to which the name of the later sceptics has been assigned. This sect seems to have originated with one Ænesidemus, a physician. It was, in fact, a school of physicians, who, in opposition to the *Methodic* sect, adopted a strictly empirical mode of treatment, and sought in sceptical considerations a justification of their practice. The grounds of this scepticism have been recorded by Sextus Empiricus It regarded not so much the validity of the notices given by the senses (to which their empirical method imposed on them a necessity of yielding their assent), as the general form and method of science. Syllogism they regarded as utterly void, inasmuch as the conclusion must have been contained in the induction on which the major proposition was founded. Perfect induction was impossible; imperfect was unsatisfactory. They also attacked, with considerable acuteness, the received doctrines of cause and effect, and of the nature of God; chiefly in opposition to the Stoics, the most dogmatical of the ancient sects. Their morality, like their speculative creed, was a system of mere sensualism. This school may be considered as the last purely Grecian sect. After them an oriental element was introduced into philosophy, which materially altered its character and bearing. The most celebrated sceptics of modern times are, Montaigne (A.D. 1580); Glanville, an Englishman, who flourished about the period of the Restoration; Bayle, and Hume. Of these Mr. Hume has the merit of producing the most systematic and comprehensive scheme of scepticism the world has yet seen. According to this philosopher, all the objects of consciousness may be reduced to two classes,—1. the impressions on the senses; and, 2. ideas, or copies of those impressions, which differ from their originals only in being less vivid. All knowledge, save that of mathematical relations, consists in the arrangement of these impressions according to the order of their succession. Of the connection between any two links of this succession we know nothing; that to which we give the name of causation being, in fact, nothing more than habitual sequence relatively to the phenomena, and custom, or often-repeated association, in relation to ourselves. All inquiry into things in themselves, or their grounds,—in other words, all metaphysical speculation, is consequently founded on delusion. The writings of David Hume, which contain his sceptical speculations, are his *Treatise on Human Nature*, and the early part of the second volume of his *Essays*. (See *Ritter*, book x. ch. 1.)

SCE'PTRE. (Gr. *σκηπτρον, a staff to lean on.*) A well-known emblem of sovereignty. Achilles, as is well known, swears by his staff or sceptre in the first book of the *Iliad*. Tarquin the elder first assumed the sceptre among the Romans. According to Justin, it was originally a spear. The sceptre of the Merovingian kings, as represented on monuments, is a rod, probably of metal, of the height of the bearer, and slightly curved like a crosier.

SCHAA'LSTEIN. A mineralogical synonym of *table spar* (tafel-spath of the Germans). It occurs in grey laminated masses or concretions, chiefly at Dognatscha in the Bannat.

SCHEELE'S GREEN. A green pigment obtained by mixing arsenite of potassa with sulphate of copper. It is an arsenite of copper.

SCHEE'LIUM. A name sometimes applied to tungsten, in honour of Scheele, who discovered it.

SCHELLING, THE PHILOSOPHY OF, teaches the identity or *indifference* of the ideal and real. Its author, Frederick Wilhelm Joseph von Schelling, was born January 27th, 1775, and studied successively at Tubingen, Leipzig, and Jena. In the latter place, he was a pupil of Fichte. Schelling lived till recently at Munich, under the patronage of the King of Bavaria, who ennobled him, and advanced him to the dignity of geheime rath, or privy councillor; but he has within the last few months accepted of an invitation from the Prussian monarch to reside at Berlin, where his lectures are said to excite the most lively interest among the Prussian literati.

It is extremely difficult to understand the true import and significancy of any particular system of philosophy, if it is considered in itself, and apart from its connection with the general history of philosophy, which, from its earliest origin to its latest development, will be found to constitute a close and compact whole. This general truth is particularly applicable to the philosophical development of Germany, the unity of whose literary pursuits seems to supply the want of a true political unity. The concatenation of views and opinions, from Leibnitz and Spinosa to the philosophers of the present day, is easily traceable; but it will be sufficient for the elucidation of Schelling's philosophy to begin with the critical theory of Kant. The transcendental idealism of this philosopher formed the transition from the empiricism of the eighteenth century, and effected, as it were, a compromise between the scepticism of Hume and the realism which it succeeded to. Without denying or asserting the existence of a material world, Kant was content with confessing an ignorance at all events of its nature. He taught that all that man can know of outward objects is, that they furnish the material ground of his conceptions; to which the mind furnishes, on its part, the form, in congruity with its original and connatural laws. Of things themselves, or, as Kant calls them, of phenomena, man absolutely knows nothing; all that he can do is to note the modes under which they appear to him. But while the criticism of the pure reason seemed to lead to a speculative idealism, that of the practical reason appeared to possess a mystical tendency. The principles of the latter work may thus be summed up:—A consideration of the exigencies of man's moral nature enforces the validity of those ideas of God, immortality, and a future state of retribution, which the speculative reason does indeed project, but cannot legitimate. The latter tendency of the Kantian philosophy was worked out by Haman and Herder, but found its culminating point in Jacobi's Philosophy of Faith (*Glauben's Philosophie*), which had many adherents in Germany, and extensively influenced the prevailing ideas of philosophy. According to Jacobi, the end and aim of true philosophy is a knowledge of God. Now, the pursuit of this object must set out from feeling and intuition, for there is no speculative method which can give a demonstration of God; for God is infinite, but the understanding finite; and all mediate knowledge by reasoning, which is a procedure of the intellect, cannot attain to the infinite. Reasoning, moreover, cannot do more than establish the correspondence of certain identical propositions from which it passes, step by step, and on the presumption of whose truth it proceeds. The element, therefore, of all human knowledge is faith; an original instinct of man's nature, which immediately reveals to him the divine; and, in spite of any suspicions of the validity of sensuous testimony, enforces a belief in the existence of an external world. The philosophical merits of Jacobi consist in this, that he did not, with Kant, regard God as a mere abstraction, but as a living spirit, whose presence is manifest within man himself; and further, in the way that he insisted on the validity of the immediate perceptions of consciousness, in opposition to the absolute authority of the finite understanding. However, true philosophical science cannot admit of any such contrariety of intellect and feeling; and to establish their identity, or at least to combine them in unison, was the problem which Fichte attempted to solve. But the predominant character of the latter's

philosophy lies in the way in which he carried, to its extreme result, the idealistic tendency of Kant. In the *Wissenschaftslehre* we have a system of pure and absolute idealism. The existence of a material world is here denied unconditionally; the real exists only so far as it is necessarily conceived by us; so that the external world is purely a creation of our conceptions, and the real is a product of the ideal. To use the language of Fichte, — the ego is absolute, and posits itself; it is a pure activity. As its activity, however, has certain indefinable limits, when it experiences this limitation of its activity it also posits a non-ego, and so originates the objective world. The ego, therefore, cannot posit itself without at the same time projecting a non-ego; which, consequently, is in so far the mere creation of the ego. With the mediate knowledge of reflection, by which Fichte attained to this speculative result, he combined for practical ends the authority of immediate consciousness. As, he argued, it is from the impulse of the ego to activity that the non-ego arises, the absolute ego is also in the same relation to the intelligent ego as a cause is to its effect. But although the absolute practical ego is absolutely free, and the sole principle of all reality, so as to posit the world in opposition to itself, and to be its cause, it has, nevertheless, a subjective limit to its operation. This is the idea of duty which the consciousness immediately announces to man as an unconditional authority and obligation; which, however, is not subversive of the freedom of the ego, but is simply an impulsive motive to its activity. Now, so far as the ego attempts to realize this duty, it tends to a moral order. He who does his utmost to establish this moral order, comes near to the Deity, and enters upon his true and proper life.

Such was the point to which speculation had attained when Schelling appeared as a philosophical writer. The subjective thought had been made the supreme and only principle, before which all objective entity was driven into the back ground; and the subjectivity of the idea was the only real existence acknowledged. For this subjective idealism Schelling, however, did but substitute an objective idealism, by giving objectivity to the idea itself, and declaring every entity to be also rational thought. Kant had spoken of the objective as unknowable; Fichte had denied its existence; and Schelling identified the ideal and the real. Fichte had confined himself to giving a derivation of nature and its laws out of an absolute and spontaneous activity of the ego. Schelling maintained that not only must the laws of consciousness be immediately cognizable in the objective world, as laws of nature; but conversely, also, the laws of nature must be immediately demonstrable in the consciousness as laws of the subjective. Man finds himself in nature, and nature in himself. Besides Fichte's method, therefore, of descending from the ego, Schelling held it to be necessary to ascend from nature up to ego. The former method is given in his transcendental philosophy, the latter in the *nature-philosophy*, which make up his system of identity. The general principles of this system are as follows: — That true and perfect science, which it has always been the object of philosophy to realize, must be one which has its authority in itself, embraces all things, and is perfectly correspondent to its object; for truth is impossible without a perfect agreement of the knowing and the known. Now, as all philosophy must proceed on the assumption that the cognizant mind is capable of true cognition, it follows that the knowing subject cannot, in its essence, be opposed to the object known; and that, consequently, it must be possible to know the real essence of things. The essence, therefore, of that which thinks and that which exists, of thought and entity, soul and body, is one and the same. By means of this essential oneness, or, in the terminology of Schelling, of this absolute identity and indifference of thought and being, the ideal and real, and in consequence of the mind being, in substance at least, homogeneous with things without it, the former is capable of representing in cognition the latter, such as they are in truth and in their essence. The knowledge thus gained is a pure intellectual intuition; it is not mere reflection, which, by its nature, cannot go beyond its data. Rising above phenomena to the ideas of the absolute, which is their identical origin, it is able to apprehend the essence of things. However, it is by reflection that man becomes conscious of these ideas through the aid of the senses; and this art of unfolding ideas by reflection constitutes Dialectics. One of the duties of this art is to trace the identical principle in its regular development, and to determine every branch of knowledge, in relation not only to the fundamental idea of the truth, but also to the cognate sciences. The true method of philosophy is the method of construction, and without it no safe step can be taken in speculative science. This method is to become fully conscious of the laws of mind, which are inherent in it; and, agreeably to them, to shape every special science conformably to the existence of things. By such a method philosophical science is possible; and this is a science of the existent agreeably to the ideas (*Wissenschaft von ideen*); that is, a science of God, and of his relation to the world, and of man and nature. According to the *nature-philosophy*, the Absolute, or God, is both thought and entity, without either unity or difference, out of which all contrariety has proceeded, and into which it will again return. As the Absolute is the sole and eternal essence of all things, every true entity, and therefore nature also, is divine, without a participation in which there can be no existence. In the eternal generation of things, the Absolute has revealed itself in infinite ways in space and time. This revelation is a living development of the infinite according to certain contraries of the subjective and the objective, the ideal and the real. These contraries strive to combine together in different proportions, and so acquire different names, according to the varying preponderance or polarity of the ideal and real. Things, consequently, are not different in their essence, but merely quantitatively, or in degree. The preponderance of the objective constitutes unconscious nature; that of the subjective is spirit. The more complete the combination of these contraries, the more perfect are the objects. The most perfect union of them, or their absolute indifference, is found in the universe; and this complete identification and reunion of them is the full revelation of God. Man, lastly, is a copy of the universe (*microcosm*), in so far as, in a manner of his own, he unites together the ideal and the real.

The philosophy of Schelling appears, then, to be directly opposed to that of Kant, from which, however, it is directly descended, not only in the nature of the knowledge which it assumes to be possible, but also with respect to the objects of that knowledge. In its essence it pretends to give a true image of the object known, and embraces, therefore, both nature and the world of man and spirits. In its method of exposition, also, it pretends to imitate the true course of the development of nature, in which every thing passes by coherent and successive steps (or *powers*, A, A^1, A^2, &c.) from the undeveloped to the developed and the perfect; and, beginning from the lowest grades of entity, passes to its higher developments.

Such is an outline of the system of Identity, as propounded by Schelling upwards of thirty years ago, and which has exercised so important an influence on the mind of Germany. There is, however, good reason to believe that the opinions of its author have been materially modified in the interval; and though, influenced by some singular feeling of reserve, which may, in fact, be said to have characterized him throughout life, Schelling has hitherto refrained from embodying his *new* views in any distinct or tangible form, yet the unaccountable leniency with which he treats his opponents in the celebrated *Vorrede* to Beckers's translation of *Cousin's Vorrede*, and the covert but ill-concealed hostility therein displayed to some of the principles on which both his own system and that of Hegel are based (see *infra*), coupled with the (unacknowledged, it is true, but still sufficiently authentic) revelations of some of his most distinguished pupils, — all these circumstances have given rise to the supposition that the long silence which he has maintained towards the public will speedily be broken by a recantation of his *old*, and his avowal of a *new* system. This conjecture has been materially strengthened by his recent call to Berlin; and the rumours which have reached us of the nature of his lectures leave little doubt of the fact, though his present views have not been sufficiently developed to warrant us in hazarding an opinion respecting them.

A brief statement of the manner in which the theory of Schelling was further modified by Hegel may be well appended here, and will complete it as a general view of the modern philosophy in Germany. In the *Encyclopædia of Philosophical Sciences*, which Hegel published in 1817 at Berlin, and designed as a manual for the use of his class, he gives a general view of his system, and clearly exhibits its ultimate tendency. "Logic," he says, "is the basis of ontology." The idea in itself and potentially is the primary substance, but *in actu* it passes into the real. The ideal is to be examined, 1st, subjectively, as it exists in the mind; 2d, objectively, or in *other*, *i.e.* in its outward manifestation; and 3d, absolutely, as it is realized in art, religion, and philosophy. Schelling had made triplicity in unity to be the law which the principle of identity follows in its outward development, and this trinary law forms also a conspicuous element of the Hegelian system. Thus he makes thought to be threefold: 1. *Formal thought*, which is independent of all subject matter, or, in the language of Hegel, of *all contents;* 2. The *notion*, or thought more fully determined; 3. The *idea*, or thought in its totality and fully determined. The last is the concrete, which is a self-developing and organical system, containing in itself all *momenta* or germs of further development. Philosophy is the right evolution of this concrete, and its true method is the dialectical momentum. The history of philosophy, apart

from its accidental media of schools and professors, is nothing less than the actual development of philosophy itself. The several systems successively recorded are but so many gradations of progress, and the latest system is the sum and perfection of all anterior ones. Thus the theories of Schelling and Hegel are essentially based on the same principle; the absolute identity of thought and being. According to the former, the mind is in full possession both of truth and reality, the knowledge of which it attains by self-consciousness in the intellectual intuition. For the latter, Hegel substituted his *dialectical momentum*, or the logical development of the idea. Generally, Hegel stood in the same relation to Schelling as Wolff did to Leibnitz. The cold and rigorous formalism of Fichte was displaced by Schelling for a loose and illogical style of political enthusiasm. Hegel, however, rightly insisted on the necessity of a scientific and systematic form as an indispensable condition of an exact science of truth. (Michelet, *Geschichte der letzten Systeme der Philosophie in Deutschland;* Jacobi, *Briefe uber die Lehre des Spinosa;* Fichte, *Die Wissenschaftslehre ; Die Bestimmung der Menschen ;* Schelling, *System des transcendentalen Idealismus ; Bruno, Oder über die göttliche und natürliche Princip. der Dinge ;* Hegel, *Phenomenologie des Geistes ; Encyclopædie der Philosophischen Wissenschaften.* For some of the more recent views attributed to Schelling, see *Stahl's Philosophie des Rechts nach geschichtlicher Ansicht, &c. &c.*)

SCHEME. (Gr. σχημα.) A plan or representation of any geometrical or astronomical figure; a diagram.

SCHE'RIF. (Arab. *lord*, or *master*.) A title given in the East, by prescriptive usage, to those who descend from Mahomet through his son-in-law and daughter, Ali and Fatima. They are also called Emir and Seid, and have the privilege of wearing the green turban. (*See* EMIR.) The chiefs of Mecca and of Medina, who are always supposed to belong to this sacred family, are styled the scherifs of those cities.

SCHERO'MA. A dryness of the eye, arising from a deficiency in the secretion of the lachrymal glands.

SCHIAH. *See* SUNNIAH.

SCHILLER SPAR. (Germ. schillern, *to change colours.*) A mineral of a pearly lustre and changeable hues. Hornblend and Labradorite are varieties of it.

SCHI'RRUS. (Gr. σκιρρος.) An induration of a gland, forming an indolent tumour, not readily suppurating, and at first unattended by discoloration of the skin.

SCHISM. (Gr. σχιζω, *I cleave.*) Separation from the true church: of which, as of heresy, it may be said that Christians are not agreed whether the mere act constitutes the crime, or whether it is only a wilful and obstinate separation that deserves to be so denominated. The chief schisms enumerated by Roman Catholic authorities are those of the Novatians, the Donatists, the Luciferians, the Greek church, and the Protestants. The great schism of the West in the 14th century holds also an important place in the history of the Papacy. *See* ANTIPOPE.

SCHI'SMA. (Gr. σχισμα.) In Music, an interval equal to half a comma; therefore eighteen of them are required to make a complete tone.

SCHIST. (Gr. σχιστος.) A Geological term adopted from the German, and applied to the varieties of slate; hence also the term *schistose rocks*, applied to those which have a slaty texture. *See* GEOLOGY.

SCHI'ZOPODS. (Gr. σχιζω, *I divide*, and πους, *a foot.*) The tribe of long-tailed Decapod Crustaceans, including those which have the legs slender and filamentous, accompanied by an external articulated branch as long as the limbs, which thus appear doubled in number; fitted for swimming, and not cheliferous, the eggs being carried beneath them, and not under the tail. The opossum shrimps (*Mysis*) are examples of this tribe.

SCHO'LARSHIP. *See* BURSARS.

SCHOLA'STIC PHILOSOPHY. That method of philosophizing which arose in the schools and universities of what are commonly called the dark ages. The father of the schoolmen was John Scotus Erigena, a native of Ireland, who lived in the ninth century. He first introduced among his contemporaries, from what source is unknown, the philosophy of Aristotle, which he combined with the doctrine of the new Platonists, and out of the combination constructed a complete system of Pantheism. These speculations were at first regarded by the church with an evil eye; nor was it before the expiration of the following century that they were applied to the purpose of explaining and supporting the leading facts of Christianity. It was probably the necessity which was felt of combating heretics with their own weapons, that caused the universal adoption of the Aristotelian philosophy by the great religious authorities of the day. It is at any rate certain, that the subtlety and ingenuity of the early schoolmen were confined to the task of constructing a scientific basis for the doctrines of the church out of the materials afforded by that system. The scholastic philosophy may be said to have expired with the conclusion of the 14th century, at least as to its influence on the leading minds of the age. Four distinct periods have been observed in the course of its development; the first beginning with its earliest commencement, and including the names of Berengarius, and Archbishops Lanfranc, Anselm, and Hildebert. The second era commences with the rise of the sect of Nominalists, the founder of whom was Johannes Roscellinus, and their most distinguished member the celebrated Peter Abelard. The third period is marked by the introduction into Europe of the writings of the Arabian philosophers, and the translation into Latin of the versions of Aristotle's writings, with the complete ascendency of realism (which see), and the now undisputed supremacy of Aristotle. The greatest names in this period, which embraces nearly all the 13th century, are those of Albertus Magnus, Thomas Aquinas, and Duns Scotus, with the respective followers of the two latter, the Thomists and Scotists. The glaring realism of Scotus roused the independent spirit of an Englishman, William of Ockam, to a closer investigation of the internal conditions of thought, and in him led to what may be considered a transition state between the formation of the old schoolmen and the tendency towards nature and experience which distinguishes modern speculations. The acuteness of this man restored the victory to the Nominalists. His nominalism, however, differed from that of Roscellinus and Abelard in the admission that "universals" have a foundation of reality in the subjective conditions of the intellect, though not an outward nature; whereas, according to the former, a general term was a name only, — a "flatus vocis." An excellent account of the leading principles of the scholastic philosophy, and the mode of its combination with the Catholic doctrines, is to be found in Dr. Hampden's *Bampton Lectures* (Oxford, 1833). The learned author, however, does not sufficiently explain the points in which the scholastic notion of Aristotle's philosophy deviates from the genuine doctrines of that profound thinker, especially with regard to the doctrine of *emanation*, a purely oriental dogma, grafted on the Grecian philosophy of the new Platonists of the Latin empire. (See *Tennemann's Geschichte der Philosophie.*)

The scholastic theology, to adopt the definition of Mr. Hallam (*Introduction to the Literature of Europe in the* 15*th*, 16*th, and* 17*th Centuries*), was, "in its general principle, an alliance between faith and reason; an endeavour to arrange the orthodox system of the church, such as authority had made it, according to the rules and methods of the Aristotelian dialectics, and sometimes upon premises supplied by metaphysical reasoning." The scholastic philosophy, according to the same author, "seems chiefly to be distinguished from this theology by a larger infusion of metaphysical reasoning, or by its occasional inquiries into subjects not immediately related to revealed articles of faith. There can be no doubt that the sudden rise and expansion of the scholastic method was favourable to the growth of mental vigour and illumination; since it substituted rigid reasoning, although on premises for the most part fanciful, for that mere acquiescence in authority which had distinguished the theology and the scanty remnant of philosophy which subsisted in the ages immediately preceding. France, Germany, England, and at one period Spain, were the principal seats of the scholastic controversies: in Italy they had less influence. Our own island has indeed the honour of having produced an unusual proportion of the chief names in this department of literature. The best known among these are Duns Scotus, before mentioned; and William Ockam, one of the last of the distinguished schoolmen who flourished in the 14th century. In the 14th century, the dialectic method of the schools was applied by some learned legists to the science of jurisprudence. Bartolus and Baldus have the highest reputation among the scholastic jurists.

SCHO'LIASTS. (Gr. σχολη, *leisure.*) The name given to the old grammarians, or critics, who used to write annotations on the margin of the manuscripts of the classical authors of antiquity, called scholia; the fruits, as it were, of leisure.

SCHO'LIUM. (Lat.) In Geometry, an explanatory observation, or excursive remark, on the nature and application of a train of reasoning.

SCHOOLS, FREE AND ENDOWED. Free schools are such as afford a gratuitous, or nearly gratuitous education, to the children of the place, from whatever source the funds be derived; endowed schools, those of which the funds arise out of royal or private endowment. The greater portion of these, in England, are also grammar schools; viz. schools in which elementary education in the classical languages is afforded, according to the intentions of the founder. A few among these have acquired, in popular phraseology, the designation of public schools. Most of these schools were founded or endowed in the century and half following the Reformation. Nearly 500 are described by Mr. Carlisle in his work on these institutions.

SCHOOLS, INFANT, are said to owe their origin to

Mr. Robert Owen of New Lanark. They have now been in operation since the year 1820. Their number is roughly estimated at 150 in England, 70 in Scotland, and 50 in Ireland, each school having on an average about 100 scholars, generally between two and seven years of age.

SCHOOLS, NATIONAL. After public attention had been drawn to the advantages of Dr. Bell's system of mutual instruction in schools, chiefly through the activity of Mr. Lancaster, two societies were formed in England for carrying it into general operation. The British and Foreign School Society was founded by Dissenters in 1805; the National Society, by members of the establishment, a few years later. The instruction of the former, in religion, is confined to those points in which all are agreed; that of the latter is founded on the liturgy and catechism of the established church. The schools of these two societies are now extensively spread over the face of the kingdom. The education given by them is nearly gratuitous, but certain small payments are in some cases exacted. Mr. Hill, in his work on the state of education in England, estimates the children attending schools of the former union at 60,000 or 80,000, and those of the National Schools at about 170,000; but these calculations seem to be founded chiefly on probabilities. The same writer estimates the average length of education in these schools at about two years for each child. Reading, writing, and arithmetic, with religious knowledge according to the principles of the respective institutions, form the amount of education generally given; but in some schools geography, and even the elements of geometry, are taught; and attempts have been made to add instruction in various branches of manual industry. Each society has a model school, and establishment for training teachers. That of the British and Foreign is in the Borough Road: the principal one of the National in the Sanctuary, Westminster; but it has others in different places.

SCHOOLS, NORMAL. Schools for the education of persons intended to become schoolmasters, teachers, or professors in any line. Normal schools form a regular part of the establishments for education in many Continental states, especially in Germany. The normal school of Paris was suppressed in 1821, but revived a few years afterwards under the name of preparatory school, and has now (since the event of 1830) resumed its original title.

SCHOOLS OF ART. See these under the heads Dutch School, Flemish School, &c.

SCHOOLS, PUBLIC. This is a name of not very definite application, by which a certain number of schools are designated, conferring a classical education, having on the average a larger number of boys, and frequented by the children of persons of rank and wealth. The principal are, 1. The three colleges, two of royal and one of private foundation,—Eton, Winchester, and Westminster. 2. Some or all of the great metropolitan endowed schools, —Charter-House, St. Paul's, Merchant Tailors', Christ's Hospital (although the last is no longer frequented except by children of the less wealthy classes). 3. Certain endowed grammar-schools in the country, raised by fashion and old reputation to the rank of public,—Harrow. Rugby, Shrewsbury, and perhaps two or three more; but here the designation becomes extremely arbitrary.

SCHOOLS, SCOTTISH PAROCHIAL. In the reign of James IV. (1494), the Scottish legislature enacted that all barons and substantial freeholders should send their children to school from the age of six to nine years, and afterwards to the academical institutions. But it was not until 1615 that the foundations of the present system were laid by an act *empowering* the bishops, together with a majority of the landlords, or "heritors," to establish schools in every parish. In 1696, by another statute, the establishment of such schools was *directed*. The appointment of the schoolmaster was vested in the heritors and minister; the burden of the expense of erecting the school and a dwelling-house for the master, and paying to the latter a salary of not less than 5*l.* 11*s.* 1*d.* nor more than 11*l.* 2*s.* 2*d.* per ann., being supported by the former. The general supervision of the schools was intrusted to the presbyteries in which they were situated. Besides the salary (which has been raised to a maximum of 34*l.* 4*s.* 4½*d.*, and minimum of 25*l.* 13*s.* 3⅝*d.*), the master is supported by trifling fees from the scholars. Reading, writing, and arithmetic, some of the branches of practical mathematics in ordinary use, and even a slight amount of classical learning, have been usually taught in these parish schools. Such is a short outline of the system, of the results of which, in the general education and morality of the poorer classes, Scotland has been so justly proud.

SCHOOLS, SUNDAY. First set on foot by Mr. Robert Parkes of Gloucester. According to Mr. Hill, in his recent work on national education, the number of children at present frequenting Sunday schools varies from 800,000 to 900,000. The average length of a Sunday-school education he estimates at four years; the education given is almost uniformly confined to reading alone; but many Sunday schools appear to have evening schools connected with them, open two or three times a week, in which writing and arithmetic are taught.

SCHOO'NER. A small sharp-built vessel, with two masts of considerable length and rake, with small top-masts, and fore and aft sails. A schooner carries a square fore-top sail and topgallant sail.

SCHORL. (Swed. scorl, *brittle.*) A mineral usually occurring in black prismatic crystals; it is brittle, and has much lustre, and becomes electric by heat and friction. *See* Tourmaline.

SCIÆNOI'DS, *Sciænoides.* The name of a family of Acanthopterygian fishes, of which the genus *Sciæna* is the type. This family is nearly allied to the Percoids; but both the vomer and palatine bones are without teeth; the bones of the head are generally cavernous, and the muzzle more or less enlarged and obtuse.

SCIA'TICA. (Gr. *ισχιον, the hip.*) A rheumatic affection of the hip joint.

SCI'ENCE (Lat. scientia), in its most comprehensive sense, is applied to the knowledge of many, methodically digested and arranged so as to become attainable by one. The knowledge of reasons and their conclusions constitutes *abstract*, that of causes and effects and of the laws of nature *natural* science. The term science is, however, more particularly used in contradistinction to *art* and *literature*. As distinguished from the former, a *science* is "a body of truths, the common principles of which are supposed to be known and separated, so that the individual truths, even though some or all may be clear in themselves, have a guarantee that they could have been discovered and known, either with certainty or with such probability as the subject admits of, by other means than their own evidence." (*See* Art.) As distinguished from *literature*, science is applied to any branch of knowledge which is made the subject of investigation with a view to discover and apply first principles. (*See* Literature.) The various sciences will be found under their particular heads.

SCI'LLITIN. The bitter principle of the squill (the bulb of the *Scilla maritima*), to which its medical properties of an expectorant and diuretic are referable. It is a white substance, of a resinous appearance.

SCINCOI'DS, *Scincoides.* A family of Saurian reptiles, of which the genus *Scincus* is the type. They have short feet, a non-extensible tongue; the body and tail are covered with equal scales, like tiles; they have no impressed lateral line, and the toes are margined.

SCINTILLA'TION. (Lat. scintilla, *a spark.*) In Astronomy, the term applied to the *twinkling* or tremulous motion of the light of the larger fixed stars; by which they appear as if the rays of light coming from them were not continuous, but produced by particles succeeding each other at intervals with a sort of vibratory movement. The planets, excepting perhaps Venus sometimes, have not this twinkling appearance; and they are thus readily distinguished from stars of the first magnitude. It arises from the extreme smallness of the apparent diameters of the fixed stars, and depends in some measure on the state of the atmosphere. In countries where the atmosphere is very pure and dry, and at considerable altitudes, the scintillation is observed to be much diminished, and the stars shine with a steady clear light.

SCIO'GRAPHY. (Gr. *σκια, a shadow*, and *γραφω, I describe.*) In Painting, &c., the art of casting and delineating shadows with truth, and upon mathematical principles.

SCI'ON. (Lat. scindo, *I cut off.*) The first young shoot produced during the year by a tree; or, more commonly, a part of a branch prepared for the purpose of being grafted upon some other tree.

SCIO'LTO. (It. *free.*) In Music, a term which, applied to counterpoint, signifies that it is free from syncopated or tied notes, or that it is not constrained by general rules. When applied to notes, it signifies that they are not tied together 
SCIO'PTIC or SCIOPTRIC BALL. (Gr. *σκια, shadow*, and *οπτομαι, I view.*) A name sometimes given to a mechanical contrivance, used in the *camera obscura*, for the purpose of giving motion to a lens in every direction.

SCI'RE FA'CIAS, in Law, is a judicial writ, which lies in various cases; most commonly to call on a party to show cause to the court whence it issues why execution of judgment passed should not be made out. It is not granted until a year and a day after judgment given.

SCI'SSEL. The clippings of various metals produced in several mechanical operations concerned in their manufacture. The slips or plates of metal out of which circular blanks have been cut for the purpose of coinage are called scissel at the mint.

SCI'URINES, *Sciurini.* Squirrel tribe. The name of a family of Rodents, of which the genus *Sciurus* is the type. They are distinguished by their very narrow

lower incisors, and by their long and bushy tail. They have four toes before, and five behind. The thumb of the fore foot is sometimes marked by a tubercle. The molars are tuberculated.

SCLE'RODERMS, *Sclerodermi*. (Gr. σκληρος, *hard*, and δερμα, *skin*.) A name given by Cuvier to a family of Plectognathic fishes, comprehending those which have the skin covered with hard scales.

SCLERO'TICA. (Gr. σκληρος.) One of the membranes of the eye. *See* Eye.

SCOLOPA'CIDÆ. (Gr. σκολοπαξ, *a woodcock*.) Snipe tribe. The name of a family of wading birds, of which the genus *Scolopax* is the type. The snipes proper have a straight beak, the nasal furrows extending to near its point, which is a little inflated externally, so as to extend beyond the lower mandible. The point is soft, and very sensible.

SCOLOPE'NDRÆ. (Gr. σκολοπενδρα.) The generic name of the Centipedes.

SCO'MBEROIDS, *Scomberoides*. Mackerel tribe. The name of the family of fishes of which the genus *Scomber* is the type. They are characterized by having a smooth body covered with small scales, and a very powerful tail and caudal fin; and include species of the greatest utility to mankind, in consequence of their abundance and flavour.

SCO'NCES. In Fortification, small forts for the deence of a pass, river, or other place.

SCO'PA. (Lat. *a little brush*.) In Mammalogy, a fasciculus of long flaccid hairs, which may grow from any limited part of the body or extremities.

SCO'PIPEDS, *Scopipedes*. (Lat. scopæa, *a broom*, and pes, *a foot*.) The name of a tribe of Melliferous insects, including those which have the tarsi of the posterior feet furnished with a brush of hairs.

SCO'RPIO. In Astronomy, the eighth sign of the zodiac, and one of the ancient zodiacal constellations. When this constellation rises, Orion sets; hence the mythological fable of the death of Orion, who perished by the sting of a scorpion. *See* Constellation.

SCOT. (Sax. sceat, *part* or *portion*, in the sense of contribution.) This old word has passed into various ordinary expressions, such as "scot-free," &c., and at one time found its way into the Italian language (Dante, *Purgatorio*). In English law it is still retained in the phrase "inhabitants paying scot and lot," which has long been held to mean paying parochial rates, and constitutes one of the old rights of voting in various boroughs existing before the Reform Act.

SCO'TER. A name of the black duck, or black diver (*Anus nigra*, Linn.), now the type of the subgenus *Oidemia*, Flem.

SCO'TIA. (Gr. σκοτια, *darkness*.) In Architecture, the name of a hollow moulding, chiefly used between the tori in the bases of columns. It takes its name from the shadow formed by it, which seems to envelop it in darkness. It is sometimes called a casement; and often, from its resemblance to a common pulley, *trochilus*.

SCO'TISTS. An old scholastic sect, followers of Duns Scotus, "the subtle doctor," one of the leading champions of Realism in the 13th century. He held that the "universal" existed not "*in posse*" only, but "*in actu*;" not depending in anywise on the conditions of the understanding, but presented to it as an outward reality. In this respect his realism differs from that of his predecessor, Thomas Aquinas, whose doctrines he combats in other respects. *See* Thomists.

SCOTODI'NIA. (Gr. σκοτος, *darkness*, and δινος, *giddiness*.) Giddiness, with imperfect vision.

SCREEDS. (Etym. uncertain.) In Architecture, wooden rules for running mouldings. Also the extreme guides on the margins of walls and ceilings for floating to, by the aid of the rules. They are always necessary for running a cornice when the ceiling is not floated.

SCREEN. (Fr. escran.) In Architecture, a partition usually wrought with rich tracery, placed behind the high altar of a church, and also before small chapels and tombs. Sometimes, as at Easter, they are placed temporarily at the sides of choirs.

SCREW. In Mechanics, one of the six mechanical powers, consisting of a spiral ridge or groove, winding round a cylinder, so as to cut every line on the surface parallel to the axis at the same angle. The screw may be formed either on the outside or inside of the cylinder; in the former case, it is called the *exterior* or *male* screw; in the latter, the *interior* or *female* screw. The action of the screw resembles that of the wedge, or inclined plane; but as the cylinder has always a handle attached to it, the screw is in reality a compound of the inclined plane and lever; and if the direction of the power be parallel to the base of the cylinder, and perpendicular to its radius, an equilibrium is produced when the power is to the resistance or pressure as the interval between the adjacent threads is to the circumference described by the point to which the power is applied. Hence the mechanical advantage afforded by the screw is proportional jointly to the fineness of the threads and the smallness of the cylinder relatively to the length of the lever or handle. It is to be observed, however, that by diminishing the distance between the threads, or diminishing the diameter of the cylinder, we diminish also, in both cases, the strength of the screw; and hence there is obviously a limit to the increase of power. But the action is greatly increased by means of the contrivance called a *double screw*, or, from the name of its inventor, *Hunter's screw*, which consists in the combination of two screws of unequal fineness of thread, one of which works within the other. In this case the power does not depend upon the interval between the threads of either screw, but on the difference between the intervals in the two screws, and may be increased to almost any extent.

The *endless screw* consists of a screw combined with a wheel and axle in such a manner that the threads of the screw work into the teeth fixed on the periphery of the wheel. Suppose the power applied to the handle of the screw, and the weight attached to the axle of the wheel, then there will be equilibrium when the power is to the weight as the distance between the threads multiplied by the radius of the axle is to the length of the lever, or handle, multiplied by the radius of the wheel.

The *water screw*, or *screw of Archimedes*, is formed by winding a flexible tube round a cylinder in the form of a screw. If the machine, thus constructed, be placed obliquely, so as to make with the vertical an angle equal to that which the spiral makes with the lines parallel to the axis of the cylinder, there will be in each convolution of the spiral a part parallel to the horizon. If any body, then, be placed within the spiral at this part, it will remain at rest; and if the screw be turned the body will ascend, because the part of the screw behind it becomes more inclined than the part before it, and it is consequently urged forward. This simple but ingenious contrivance is usually employed for the purpose of raising water to a small height, but it may be employed to raise any substance that can pass within the tube; and it is evident that the action may be increased by placing several tubes or spiral channels (for they may be formed of wood or iron) on the same cylinder. The principle has been recently applied to the propelling of steam-vessels.

The *micrometer screw* is a contrivance adapted to astronomical or optical instruments, for the purpose of measuring angles with great exactness. The very great space through which the lever of the screw passes in comparison of that which is described by the cylinder in the direction of its length, renders the screw of immense use in subdividing space into minute parts.

As a mechanical power, the screw has innumerable applications; but it is employed with most effect in all cases in which a very great pressure is required to be exerted within a small space, and without intermission. Hence it is the power generally used for expressing juices from solid substances, for compressing cotton and other goods into hard dense masses for the convenience of carriage, for coining, stamping, printing, &c.

SCRIBES. The copyists, and at the same time the interpreters of the law, in the later periods of the Jewish history. They were held in great honour among that people, and ranked with the priests themselves in their estimation. In the New Testament, we find them generally referred to in connection with the Pharisees, to which sect they appear generally to have belonged, and with whom they coincided in temper and sentiments. Some ancient writers conceive the scribes to have formed peculiar sects in themselves; but there is no authority for this opinion.

SCRI'BING. (Lat. scribo, *I write or scratch*.) In Architecture, fitting the edge of a board to another board in the same plane as the edge. In joiner's work, it is the fitting one piece of wood to another so that their fibres may be respectively at right angles.

SCRI'PTURES. The Holy Scriptures, or writings of the Old and New Testament. The Canonical Scriptures, which, having been duly authenticated, are inserted in the canon or rule by which the faith of a believer is determined. *See* Bible, New Testament, Old Testament.

SCRI'VENER. (From the Lat. scribo, *I write*; apparently through the Spanish escribano.) Money scriveners, in old English usage, were parties who received money to place it out at interest, and supplied parties who wished to lend money on security. Money brokers and attorneys who practise in this manner have been held to be within the statutes relating to scriveners. In this sense, the word is obsolete. The last regular scrivener is said to have been a person of the name of Jack Ellis, a cotemporary of Dr. Johnson, mentioned in *Boswell's Life*. The city company of scriveners remains to attest the ancient importance of the business.

SCRO'FULA. This disease was originally termed χοιρας, or *swine disease*, by the Greeks; and later nosologists have translated it by the term scrofula. It consists in indurated glandular tumours, especially about the neck, which, when they suppurate, discharge a white curdled matter, unlike healthy pus. Scrofula is not con-

tagious, but often an hereditary disease, and dependent upon a peculiar predisposition in the constitution: its first appearance is usually between the third and seventh years of the child's age, and it seldom shows itself after the age of puberty. It is most common among delicate children with fair complexions, and those disposed to rickets. It is rare in warm climates, and seems to be favoured by cold and variable countries. It is promoted by every thing that debilitates; and when its exciting causes are by any accident not brought into action, it may even remain dormant through life, and not show itself till the next generation. In mild cases the glands, after having suppurated, slowly heal; in others the eyes and eyelids are inflamed, and the joints become affected, the disease gradually extending to the ligaments and bones, and producing a hectic and debilitated state, under which the patient sinks; or it ends in tuberculated lungs and pulmonary consumption. In the treatment of the mild and simpler forms of scrofula, the diet should be nourishing and invigorating, and a dry situation and sea air are to be sought for; great attention should be paid to the clothing, so as to avoid colds and coughs; and tonics and gentle stimulants, with mild narcotics, and occasionally the alkalis, should be prescribed. Iodine has sometimes appeared of much service, but it requires the greatest circumspection in its internal use; it may be applied externally, as may also sea water and other saline lotions. Chalybeates and mercurials are frequently prescribed; and much benefit has, in some instances, been derived from a course of sarsaparilla.

SCROPHULARIA'CEÆ. (Scrophularia, one of the genera.) A natural order of herbaceous or shrubby monopetalous Exogens, inhabiting all parts of the world, except the coldest. The stamens are either didynamous or unsymmetrical; nevertheless, the affinity of the order is undoubtedly with *Solanaceæ*, through the medium of the tribe *Salpiglossideæ;* so that it becomes necessary to separate them by a mere artificial distinction, considering as *Solanaceæ* such genera as have a plaited corolla and five stamens, and as *Scrophulariaceæ* all those in which the fifth stamen is wanting, or the æstivation of the corolla imbricated. They are generally acrid, bitterish plants. The leaves of some are purgative, and even emetic, a property so much increased in digitalis that its effects become highly dangerous; and nearly all the tribe turn black in drying. Many of the genera, such as digitalis, calceolaria, &c., are valued by gardeners for their beautiful flowers.

SCRU'PLE. A denomination of weight; the third part of a dram, and equal to twenty grains. *See* WEIGHTS.

SCRU'TINY. (Lat. scrutor, *I examine.*) In the Primitive Church, an examination in the last week of Lent of the catechumens who were to be baptized on Easter-day; used chiefly in the ancient church of Rome. In parliamentary language, an examination of the votes given at an election by an election committee, at which the bad given on both sides are rejected, and the poll corrected accordingly, is called a *scrutiny*.

SCUD. The name given by seamen to loose vapoury clouds driven swiftly along by the winds. *To Scud*, signifies to run directly before the wind in a gale. As the object is to keep before the sea, the fore sail or foretop sail is set: the latter or the maintop sail is often necessary, as the fore sail is often becalmed from the height of the waves.

SCU'DO. *See* MONEY.

SCULL. An oar, so short that one man can work a pair. It most generally implies an oar placed over the stern of a boat, and worked from side to side; the blade, which is turned diagonally, being always in the water. In China, where the method is well understood, large boats are impelled by a single scull with considerable velocity.

SCU'LPTURE. (Lat. sculpo, *I carve.*) The art of carving in wood, stone, or other materials. The origin of sculpture is so remote, that at this period there neither exists the probability of any authentic account of it being satisfactorily deduced, nor even the indication of that nation in which it first appeared. Though idolatry may have favoured its early advances, and rendered it powerful assistance, we are not indebted to religion alone for its invention. In Egypt, indeed, it may be said that its progress was impeded by the restraints and shackles with which religion invested it. "The monstrous shapes and sorceries" of "fanatic Egypt" clearly barred its perfection in the country, where a bird's head was combined with the body of a lion, and cats' and wolves' heads were joined to the divine form of man. It was in Greece only that the unnatural junction of the two noblest animals was successful, and grace and dignity resulted from the attempt in creation of a centaur. The first artist on record as a sculptor is Bezaleel, who, with Aholiab (see Exodus, xxxi.), formed the cherubim that covered the mercy-seat; but, previous to these, the art of moulding and working in metal was long known. The presents to Rebekah consisted of jewels of silver and gold; Judah gave to Tamar his signet and his bracelets; in Egypt "Pharaoh took off his ring from his hand, and put it upon Joseph's hand." Then, as to the art of moulding or carving, from the use of idols, we know it must have existed in Asia, and in Egypt from the time of Abraham and Jacob. The *teraphim*, which Rachael stole from her father (Gen. xxxi. v. 19. 30.), were, according to the best commentators, carved images in a human form, and household deities, like the penates and lares of the Romans many centuries afterwards. The commandment will doubtless occur to the reader, "Thou shalt not make to thyself any graven image;" as well as the address of Moses to the Israelites, "For ye know how we have dwelt in the land of Egypt, and how we came through the nations which ye passed by; and ye have seen their abominations, and their idols of wood and stone, silver and gold, which were among them."

Some of the most extraordinary specimens of early sculpture on record are described by Diodorus as the works of Semiramis; but they are too wonderful to allow of our implicit reliance on the author. She is said to have had representations in brick on her palace of every sort of animal in relief. These were afterwards so coloured to nature as to have the appearance of life. In the midst of them was represented Semiramis piercing a tiger with a dart, and near her Ninus killing a lion with his lance. In another part of the same palace were placed the statue of Jupiter Belus, those of Ninus, Semiramis, and the principal officers of the state, the whole executed in bronze. We are also told that, by command of this princess, a temple was raised at Babylon, on the top whereof three massive statues were placed of Jupiter, Juno, and Rhea. That of Jupiter was forty feet in height. Stupendous as these works are stated to have been, we gather from the same author an account of the execution of one which throws them into insignificance. One of the sides of the mountain Bagistan was extremely rough and steep, and seventeen stadia in height; this she caused to be reduced to a smooth surface, and then sculptured into a figure of herself, attended by one hundred of her guards. It is to be observed that Diodorus relates this story on the authority of Ctesias. Doubtful as it is, the same sort of scheme was proposed to Alexander by the architect Dinocrates, as related by Vitruvius in the preface to one of his books.

Of the sculpture of the Persians little notice is necessary. In the article PAINTING we have mentioned that it was contrary to the tenets of their religion to make in any way representations of the human form. In Persepolis there are, however, some extraordinary sculptures, bearing considerable resemblance to the style of the Egyptian bassi-relievi in the palace of Thebes, allowing for the difference of dress; but they contain nothing in science or imitation particularly worthy of our notice. The earliest sculpture to which we can refer, and on which we can reason, is that of the Egyptians. Herodotus tells us, that they erected the first altars and temples to the gods, and carved the figures of animals in stone. The abundance and variety of the specimens still in existence of their sculpture, minute and colossal, domestic and religious, prove them to have been a nation with prodigious resources, and distinguished for their wisdom and affection for the arts. The greater portion of their sculpture seems to have been sacred; that is, representations of the divinities, and their attributes and qualities. In respect of the dimensions of some of their statues, Herodotus mentions one before the temple of Vulcan at Memphis, and another at Sais, placed there by king Amasis, each of the height of seventy-five feet. The part of the sphinx, near the great pyramid, still out of the sand, that is, from the throat upwards, rises to the height of twenty-five feet. At Thebes the sitting statues of Memnon, the mother and the sons of Osymandyas, are each fifty-eight feet high. A long catalogue might be added to these: we will, however, only add, that in the British Museum is a closed hand, which must have been part of a statue sixty-five feet high. Grace of form, elegance, and symmetry, are not to be found in Egyptian sculpture. The faces of their statues have a resemblance to the Chinese, and their bodies are formed with large bellies. They generally stand equally poised on both legs, having one foot advanced; the arms either hanging down straight on each side, or if one be raised, it is at a right angle across the body. Some of their statues are seated, and some are kneeling; the position, however, of the hands is rarely different from what we have described. The faces of them are generally flat; the brows, eyelids, and mouths formed of simple curves slightly marked, and with little expression. The tunics and draperies are frequently without folds.

The arts of Egypt seem to have been in a progressive state of improvement from about or before the period of Moses to the invasion and subjugation of the country by Cambyses, a thousand years afterwards. Winckelman thinks that there were two distinct styles; the first ending with the conquest just mentioned, and the second commencing at that period, and ending after the time of Alexander the Great. In the first of these styles he de-

scribes the forms as straight, stiff, and ungraceful. The sitting figures have the legs always parallel; the feet are squeezed together, and the arms fixed to the sides. In the females the left arm is generally folded across the breast, and the draperies exhibit very little skill or knowledge. In the second style the hands become more elegant; the feet are placed at a greater distance from each other, the arms hang more freely, and the figure is generally clothed with a tunic robe and mantle. The material usually employed is granite or basalt: the statues are not only formed with the chisel, but polished carefully; and the eyes are sometimes formed of different materials from the statues themselves. Small figures are frequently found, to which the name of penates has been given; they are sometimes composed of wood, sometimes of baked earth, and some are covered with a green enamel.

"Winckelman," says Flaxman in his Second Lecture on Sculpture, "has remarked that the Egyptians executed quadrupeds better than the human figure; for which he gives the two following reasons: first, that as professions in that country were hereditary, genius must have been wanting to represent the human form in perfection; secondly, that the superstitious reverence for the works of their ancestors prevented improvement. This is an amusing but needless hypothesis; for there are statues in the Capitoline Museum with as great a breadth, and choice of grand parts, proper to the human form, as ever they represented in their lions or other inferior animals. In addition to these observations on Egyptian statues, we may remark, the forms of their hands and feet are gross; they have no anatomical detail of parts, and are totally deficient in the grace of motion. This last defect, in all probability, was not the consequence of a superstitious determination to persist in the practice of their ancestors; it is accounted for in another and better way." This "better way" of the professor is from their being deficient at the time in geometry, which, *he* says, "will naturally account for that of motion in their statues and relievos, which can only be obtained by a careful observation *assisted by geometry*." We confess we are not convinced with the reason given; and with all respect for the splendid talents of the professor, whose own knowledge of geometry, from his curious definition of the centre of gravity in the human figure, we apprehend to have been exceedingly limited, we rather prefer the hypothesis of Winckelman. The Egyptian bassi-relievi are usually sunk from the surface of the material employed, which practice most probably obtained from their being cut in very hard stone, such as granite or basalt, and from the distance they were usually placed above the eye. In the first case, cutting the ground away from the figure would have occupied quite as much time as carving the figure itself; and in the second case, the range of the outline created a greater breadth of shadow and distinctness to the spectator. These bassi-relievi, or hieroglyphics, when found on the walls of tombs, relate the profession, actions, and funeral of the deceased; on those of palaces, the wars, negotiations, triumphs, processions, trophies, with the civil, military, and domestic employments of kings; on those of temples they were the records of theology; and on obelisks they are hymns to the gods, or eulogies of their kings.

The only correct notions that can be obtained on the subject of Phœnician sculpture is from a contemplation of the medals of the Carthaginians, who were a colony from Phœnicia; though perhaps these may mislead us. The Phœnicians, known by the name of Canaanites in Scripture, were at a very early period advanced in civilization. When Moses sent out the spies to search the land of Canaan, they returned with an account, "that the people be strong that dwell in the land, and the cities are walled and very great." It was from Chaldea, according to the authorities cited by Jacob Bryant, that the arts of the Phœnicians were derived having first been transplanted to Egypt. Beautiful in their own persons, they were, unlike the Egyptian races, themselves models for their artists, and their situation and character were favourable to the progress of the art. Their extraordinary and successful spirit of commerce led to its cultivation, and some of the statues that decorated their temples were celebrated in history. Winckelman is of opinion that the Etrurians, or ancient Tuscans, carried sculpture to a certain degree of perfection much earlier than the Greeks. The same Dædalus who has the reputation of having taught this art to the Greeks, has a similar good office assigned to him by historians towards the Etrurians; for, in order to escape the resentment of Minos king of Crete, he is reported to have taken refuge in Sicily, whence he passed over into Italy. Etrurian art proves that the first attempts towards sculpture were in clay, whereof innumerable specimens have been found in Rome and its environs; and as the Romans in the early period of their existence as a people were entirely ignorant of the arts, no doubt is left of these specimens being the work of the Etrurians or Volscians. Clay was for a long time the only material used — "nulla signa, statuæve, sine argillâ;" and Pliny and Varro tell us that the Hercules, the Jupiter Capitolinus, the quadriga on the top of his temple, and all the other statues of the gods before the temple of Ceres was erected, were "Tuscanica omnia." Many of the Etruscan statues bear so striking a resemblance to those of Greece, that antiquarians have thought it probable they must have been brought from that country, or from Magna Græcia into Etruria, about the period of the conquest of Greece by the Romans, when Italy became almost saturated with the magnificent spoils of art which that country yielded. The Etruscan sculpture is in two distinct styles of art. In the first or earliest style, the general lines, or contours, are exceedingly stiff and straight, and the attitudes exhibit any thing but a feeling of ease in the figure: the form of the head is entirely devoid of beauty, the outlines not well rounded; their figures are almost invariably too slender; the form of the head is oval, the chin piked, the eyes flat, with some degree of tendency towards squinting. All these defects indicate an infant state of the art, and it is not extraordinary to see the very same defects in the works of the Gothic sculptors. The second style of Etruscan art is conjectured by Winckelman to be contemporary with the age of Phidias; but it is to be observed that this conjecture is in no way borne out or supported by proof. In this style the joints are strongly marked, the muscles raised, the bones perfectly distinguishable, and considerable knowledge of the science of anatomy is displayed. The statues of the gods are executed with delicacy, and there is a show of great power without violent distension of the muscles. The attitudes, however, are far from natural, and the action constantly overstrained. To this Millin adds a third period in the history of Etruscan art, commencing at the conquest of Greece by the Romans, at which time the Etruscan artists became acquainted with the works of the Grecians, and, adopting their style, became at first their imitators, and afterwards their rivals. To the Italian artists of this period Horace is supposed to allude in one of his satires. In concluding this succinct account of the sculptures of Etruria, to exhibit the extent to which it was cultivated it is only necessary to state, on the authority of Pliny, that when the Romans conquered Volsinium, one of the twelve cities of Etruria, they carried away from that city alone about 2000 statues.

Before turning to the sculpture of the Greeks we may notice, as bearing some resemblance to the Egyptian sculpture, that of the Hindus. It is not, however, intended to compare the one with the other; for the latter is far more deficient than the former, both in science and resemblance to nature. The stupendous excavations at Ellora, which have been mentioned in the article ARCHITECTURE, and those at Elephantis and other parts of India, are well known by representations which have been published in this country. They are by some considered of very high antiquity, and are decorated profusely with mythological sculpture, whereof the subjects are symbols, allegorical figures, and groups expressive of the attributes and energies of divinity, according to the Brahmin doctrines. The reader who is desirous of further information on this subject may profitably consult *Moore's Hindu Pantheon*, which contains upwards of 1500 outlines of Hindu painting and sculpture faithfully delineated from the originals.

As we have seen, the first dawn of the art was on the soil of Phœnicia and Egypt: we have now to trace it to its meridian splendour on the shores of Greece. In Egypt the forms of the human figure, and its "face divine," far removed from beauty and intellectual expression, a burning climate, and institutions inimical to improving on the model, restrained the art within very narrow bounds; whereas in Greece the beautiful forms of the male and female models, the genial and delicious climate, were among the leading physical causes of the supereminent success of the Greeks. With them, says D'Agincourt, "au lieu de noirs scarabées, du chacal, ou de la hyène féroce, du hideux crocodile, c'étaient les diligentes ouvrières du mont Hymette, le noble coursier, le taureau vigoureux, le cerf agile, l'élégant et doux chevreuil, qui peuplaient les rives émaillées de ses fleuves, ses riantes collines, ses forêts ombragées." With them, unlike the attachment to the combinations of human with the brutal forms of Egypt, the softest desires, the noblest and liveliest emotions of the heart, found continual nourishment in the splendid and affecting spectacles which the religion of the nation constantly exhibited. The institution of public games, at which all men of consideration and celebrity, and of whatever rank, contended for honours, and the beauty of form to be seen at them, which was an unceasing object of contemplation, raised them into a nation of connoisseurs. No crowns, no honours decreed by a congregated assemblage of intelligence, awaited the monotonous labours of the Egyptian sculptor: his works were to be executed in conformity with the practice of former ages. Egypt abounded with artisans, Greece with artists.

Greek sculpture has usually been arranged under three epochs, which we shall here enumerate. We of course pass over the rude and unfashioned representations of the

divinities of the primitive ages, which Pausanias tells us were little more than blocks of stone, though regarded to the last with the greatest reverence, and to be seen as late as the time of Adrian at Thebes, Argos, and other cities; and which, indeed, were rather symbols than representations. Neither do we think it here necessary again to touch upon the works of Dædalus and Endæus, about which we can now form no just conception, except that the material they employed was wood. About 775 B.C., Dipœnis and Scyllis the Cretan became celebrated for their marble statues, which retained much of the ancient style in the advancing position of the legs, the general form of the figure, and particularly in the vertical folds of drapery, whose edges were zigzag. Soon after this period sculpture received the most elaborate finishing, though the character of the face and limbs was not much changed from the tasteless and barbarous style of former times. Flaxman conjectures that the colossal busts of Hercules and Apollo in the British Museum may have been the works of Dipœnis and Scyllis. It is not difficult to conceive the progressive improvement in an art so much cultivated, between the time of which we are now speaking and the first epoch in which Ageladas, the master of Polycletus, appeared. Ageladas, with whom has been confounded Eladas or Geladas, the master of Phidias, was a native of Argos, and cotemporary with Pisistratus. It was at this period that art approached the personification of ideal beauty by the choice of forms from many models, so that the excellence found in each might be combined in one. Its cultivation had become an object of necessity in most of the Grecian states, induced greatly by a practice introduced about this era, of honouring with a statue every individual who had received three crowns in the public games. Such a custom afforded the artist the opportunity of contemplating some of the most perfect examples of living beauty, from which were afterwards deduced those canons of proportion on which all future art has been unable to improve. Within the interval of which we have just spoken appeared the sculptor Callimachus, to whom Vitruvius assigns the merit of having invented the Corinthian capital. (*See* ARCHITECTURE.) "The better drawing of the figure, with a more careful attention to its parts, more precision and variety of attitude, a less elaborate curling and dressing the hair, the form of the figure better shown through the drapery, are all certain signs of a near approach to the age of Phidias."

The second epoch of sculpture among the Greeks was in the age of Phidias, who flourished about 490 years before the Christian era,—a period peculiarly splendid in history, as abounding with statesmen, warriors, artists, philosophers, and poets; among whom will doubtless occur to the reader the names of Socrates, Plato, Pericles, Miltiades, Cimon, Themistocles, and Xenophon. The emulation among such rare talents as then appeared was highly favourable to the growth and perfection of genius. Athens, destroyed by the army of Xerxes, rose under the auspices of Pericles in renewed and far greater grandeur. Phidias, the pupil of Eladas the Argive, though by some it is thought that honour belongs to Hippias, was employed by Pericles in the superintendence of the public works; and the admiration of his powers was so universal with the ancients, that Quintilian says, speaking of his Athenian Minerva and Olympian Jupiter at Elis, "Cujus pulchritudo adjecisse aliquid etiam receptæ religioni videtur, adeo majestas operis deum æquavit." Plutarch affirms that Callicrates and Ictinus executed the work of the Parthenon; and this, as far as relates to the latter, is confirmed by Pausanias. The statue, however, of Minerva, of ivory and gold, within the temple, was the work of Phidias himself; and, excepting his Jupiter at Elis, his most celebrated production, some have doubted that Phidias himself ever worked in marble; but although his chief material was bronze when he did not use ivory, it is certain that he occasionally wrought in marble. The great reputation of Phidias was founded upon his representations of the gods, excelling more in them than in human forms; and in his works in ivory it is said he was unrivalled. Polycletus, the scholar of Ageladas above mentioned, and cotemporary of Phidias, assisted in the perfection of style of the second epoch. He was of Sicyon, and especially celebrated for his Doryphoros, or lance-bearer, and his Diadumenus, or youth binding a fillet round his head. The first was so esteemed by artists, that it was called the "canon," from which they studied their proportions. There is, however, some doubt whether it be this or another statue to which this honour was paid. The cotemporaries of these great men were Callon, Phragmon, Gorgias, Lacon, Myron, Pythagoras, Scopas, and Perelius. In a passage of Pliny, Alcamenes is classed with Critias, Nestocles, and Hegias, who are called the rivals of Phidias. The name of Colotes is preserved as another of his scholars.

The third epoch is that in which we become acquainted with the names of Praxiteles and Lysippus, and in which what Winckelman calls the *fine style* was introduced. The graces of youth and beauty were the delight of Praxiteles; and in his marble statues at the Ceramicus of Athens, he is said to have excelled himself. His Venus of Cnidos was so endowed with charms, that her suitors were seaborne from all quarters to pay homage at her shrine. This statue, which had been rejected by the Coans on account of its being naked, was refused to Nicomedes by the citizens of Cnidos in payment of a debt of immense amount. It remained at Cnidos in the time of the Emperor Arcadius, about 400 A.D. Flaxman in his Lectures observes of it, that it "seems to offer the first idea of the Venus de Medicis, which is likely to be the repetition of another Venus, the work of this artist." A satyr, Cupid, Apollo (the lizard-catcher), and Bacchus leaning on a fawn, are known works of this master. Cotemporary with Praxiteles was Lysippus, so celebrated for the group of horses still to be seen in the front of St. Mark's church at Venice. This epoch, though that which Winckelman calls of the fine style, is not in grandeur comparable to its predecessor. The refinement of art was carried almost to its utmost limit: greater delicacy and voluptuousness may indeed have been and was introduced into the female forms, but in dignity and simplicity of feeling it is inferior to the extraordinary productions of the age of Phidias. After this period several of the finest groups and statues were nevertheless executed: one of them, the Laocoon (*see* LAOCOON), is in a very high class of art, and perhaps not inferior to any group known. The principal schools of sculpture were Athens and Rhodes; from which latter school came the Laocoon, the Torso Farnese, and the Colossus. To what extent the Rhodians were sculptors may be conjectured from the circumstance of the Romans carrying off from this little island 3000 statues. After the death of Alexander the Great, 324 years before Christ, the arts of design seem to have declined from their meridian excellence. Apelles found an asylum in Egypt with Ptolemy, a prince whose liberality induced artists to repair to his dominions, and whose example in this respect was followed by his successor; but under the detestable tyranny of the seventh of that dynasty, the artists abandoned Alexandria altogether. The alternate favour and disgrace which they experienced under the kings of Syria, and those of Bithynia and Pergamus, was repeated in Sicily under Agathocles and Hiero II., till the taking (212 B.C.) of Syracuse by Marcellus, who was the first to appreciate Greek statues as invaluable ornaments to the "eternal city."

At the conclusion of the Macedonian war, 500 marble and bronze statues graced the triumph of the conquerors. Mummius and Scylla left no place unstripped of all in the shape of art upon which they could lay their hands; and within a very comparatively circumscribed period Rome became the rendezvous of all artists who had any pretensions to talent, for it was the only place in which they could obtain employment.

The Romans had no natural taste in the fine arts, nor any style of their own originally; and down to a late period they employed the Etrurians in all works of art. Tibullus characterized the art in its early age by the line,

Stabat in exigua ligneus æde deus;

and even to its last hour it may be truly averred that sculpture never shone in Rome except with a borrowed light. Volsinium, one of the twelve cities of Etruria (the modern Bolsena), was called the city of artists; and it was this depôt which for a long time supplied the Romans with architects, painters, and sculptors, and taught the Romans at an early period what little they knew of art. Before the 5th century of its existence the use of marble was scarcely known in Rome; but in the 6th, the Romans began to spread themselves towards the regions inhabited by Grecians, and imbibed a taste for the expensive materials used by that nation.

The year 146 B.C. was signalized by the entire reduction of Greece under the dominion of the Romans. Sixty-six years previously a dawn of luxury and taste had opened at Rome by the introduction, through Marcellus, of statues from Syracuse; but though the increasing luxury of the Romans created a constant demand for fresh objects of the art, its history in the city is but a melancholy continuing decline of it, its energies and beauties being destined to expire among the people of a strange land. The only occupation then left for Greek artists was to be found in Rome, whither they were invited, and where abundance of them were to be seen. Among them Pliny (l. xxxv. c. 12. and xxxvi. c. 5.) mentions the name of Pasiteles, a sculptor, who wrote five volumes, containing a catalogue raisonnée of the finest works of art known in his time. Pasiteles excelled as a modeller in metal. The silver statue he executed of Roscius, as also his vases, were highly celebrated. Archesilaus, Topirus, and Evander, all Athenians, were among his cotemporaries in the Augustan age. The first of these who excelled in marble is extolled by Pliny for his care in modelling before he began upon the block. He was the friend of Lucullus, for whom he executed a group,

described by Varro, representing a lioness with cupids sporting round her, and endeavouring to force her to drink. Still, however, the passion for ancient Greek statues prevailed with the Romans. Martial says, in speaking of a statue of Hercules,

Non est farina recens, nec nostri gloria cœli:
Nobilis Lysippi munus, opusque vides.—(Lib. ix. Ep. 45.)

Under Augustus the art had not been entirely divested of grand and noble feeling; but after his time it partook very much of the character of his successors as they appeared. Licentious and obscene under the sway of the vicious, debauched, and cruel Tiberius; under Caligula it became so grossly flattering, that ancient Greek statues of the gods were decapitated to make room for the head of this emperor. Under Nero (to whom, however, we perhaps are indebted for the preservation of the Apollo of the Vatican and the Borghese gladiator, which were found in his villa at Antium) it became so outré and extravagant, that some of the statues of Lysippus were actually gilt. It has been conjectured that the Apollo and gladiator above mentioned were part of the spoils from the temple at Delphi. The reigns of the three emperors that succeeded Nero were of such short duration, that had they been so minded they had not sufficient time to inflict any very serious injury on the arts. Vespasian, whose only blemish was avarice, which is even extenuated by the laudable and patriotic use he made of his revenues, cultivated the arts as well as literature. The Temple of Peace, which was really a temple of the arts, was by him decorated with the choicest specimens of Greek painting and sculpture. The reigns of his son Titus and of Trajan were also favourable to sculpture. The latter was the patron of Apollodorus, from whose hand is the sculpture on the column that bears the emperor's name and records his military exploits. Trajan, moreover, had the liberality and good sense to erect statues in honour of the eminent men of his time. The works of this period were, however, rather architectural than sculptural, such as temples, palaces, triumphal arches, &c., and the sculpture chiefly in request was for their decoration; a want certainly not calculated to retrieve the art from its sinking state, but rather to encourage bold and offhand execution at the expense of simplicity and expression. Adrian was so great a lover of the arts, that he did not think it beneath his character as emperor himself to exercise those of painting and sculpture for his amusement. He not only restored the principal buildings at Athens, but extended his fostering care to the temple of Jupiter at Olympia, where he caused to be erected a colossal statue of the god in gold and ivory. The statue of Antinous, so generally known, was the work of this reign. Antoninus and Marcus Aurelius were appointed by Hadrian as his successors; under them the art revived for a time, and has acknowledged her gratitude to the last by his bronze statue at the Capitol. The former crowded with the choicest specimens of sculpture he could procure his villa at Lanuvium. How sculpture was encouraged at this time may be gathered from the innumerable busts of these emperors that have reached us. Commodus had likewise been honoured with a multitude of statues, but these upon his death were decreed by the senate to be all destroyed. Only thirteen years afterwards, under Septimius Severus, the decay of the art became very manifest: its decline continued during the reign of Alexander Severus, though two busts of him, which were discovered a few years since, are not without merit. During the next half century, the rapid succession of twenty emperors, scarcely one of whom died a natural death, gave to sculpture little chance of a revival. In fact, by the end of the 4th century it was extinct; of which no other proof is necessary than the arch of Constantine and the statues of that prince, through whose removal of the capital of the empire to Constantinople Rome no longer swayed the sceptre of the fine arts. If the Romans do not deserve the admiration in which the Greeks are held for their knowledge of the fine arts, they deserve our gratitude for their instrumentality in preserving some of the noblest productions of the art of sculpture. There are two epochs under which the taste of the Romans for the fine arts may be classed: the first beginning with the capture of Syracuse by Marcellus, and ending at the time of Julius Cæsar; the second, that of the Augustan age, in which all the polite arts flourished.

From the 4th to the 13th century, if there were materials sufficiently authentic, the history of the arts, as we have shown also in the articles ARCHITECTURE and PAINTING, is such a blank as to be scarcely worth the trouble of tracing. In the 13th century, however, the clouds of darkness began to separate, opening a dawn for their revival in the 14th, which was soon afterwards to bring on the blaze of day. We shall divide our account of the art from this period into three epochs.

First Epoch.—The Roman power having been entirely destroyed in the West of Europe, Italy became divided into republics and principalities, whereof the chief were Venice, Genoa, and Pisa, these being the earliest in fully establishing liberty. The last, however, was foremost in founding a schoool of native art. The Pisans, who possessed considerable extent of coast, had beaten the Saracens in Africa, Sardinia, Majorca, Minorca, and Sicily; and had thus acquired the treasures with which they commenced the erection of their cathedral, which was finished in 1092, about seven years after that of St. Mark at Venice had been consecrated. Schools of painting, sculpture, and architecture, soon arose after this period, and the cause of religion found employment for the talent they produced. It has been conjectured that Buschetto, whom the majority of writers and weight of argument prove to have been a Greek, though thought by some to have been an Italian, was the founder of the school at Pisa. The reputation of this school was raised to the greatest height by the appearance of Nicolo de Pisa, the pride and glory of the 12th century, and the first who on its restoration gave dignity and importance to sculpture. That the Grecian fragments which the Pisans had acquired soon enabled Nicolo to discriminate between them and the style of Buschetto, is evident from some remains of his work in the Campo Santo. In 1225 he was employed at Bologna in decorating the sarcophagus of St. Dominic, in which his admiration and successful imitation of the antique shine forth. He was afterwards engaged on the bas-reliefs of the pulpits at Pisa and Sienna, and on the façades of the cathedrals at Orvieto and Lucca. The time of his death is uncertain. Giovanni, the son of Nicolo, succeeded his father, to whom in some respects he was more than equal. Their figures, especially those of their draped females, are elegant, and exhibit "an originality of idea and a force of thought seldom met with when schools of art are in the habit of copying from each other." The school of Pisa is not limited to the two we have just named. Arnolfo the Florentine, the brothers Agostino and Agnolo, and Andrea Ugolino, all deserve to be recorded. Andrea executed in bronze the oldest gate of the baptistry at Florence, on which is represented the life of St. John. This work is designed with much grandeur and simplicity, and almost if not quite equal to his master; but in his marble statues he is inferior. Giovanni da Balduccio, scholar of Nicolo or Giovanni, was of this epoch: his first works were at Milan, where afterwards, in 1339, he executed the mausoleum of St. Peter the Martyr. In the 14th century Giotto established a school, distinguished by good drawing, which prepared Florence for a perfect re-establishment of the art. Of it was Orgagna, a name ever to be remembered for his celebrated loggia at Florence, who was also eminent for his works in sculpture. A school at Sienna, towards the end of this century, produced Jacopo della Quercia, whose principal works were at Bologna, Lucca, and especially Sienna, where a fountain which he designed was so admired that he acquired the name of Jacopo della Fonte. From his hand is the bas-relief in the façade of San Petronio at Bologna. The 15th century was a splendid era for the production of every thing that was great and intelligent, and most especially for the art of sculpture. The love of liberty and knowledge seemed to animate the whole of the Italian republics; and as if the republic of the arts were not excluded from the common sentiment, no individual master seems so to have outstripped his rivals as to have impressed the art with his own particular style.

This period brings us to the *second epoch*, at the beginning whereof we find six great artists engaged in a competition for executing the bronze doors of the baptistry at Florence, in which, after a year's trial, Lorenzo Ghiberti bore away the palm from his rivals. Among these was Donatello, a Florentine, one of the most distinguished restorers of the art. "Some of his works," says Flaxman, no incompetent judge, "both in bronze and marble, might be placed beside the best productions of ancient Greece without discredit." His alto-relievo of two singing boys in the Duomo at Florence is, in point of character, sentiment, drawing, and drapery, of extraordinary beauty. The marble statue he executed of St. George standing upright, equally poised on both his legs, with his hands resting on the shield before him, so excited the admiration of Michael Angelo, that after contemplating it in deep silence for a considerable length of time, he suddenly exclaimed "March." Lorenzo Ghiberti, the contemporary, and, as we have before mentioned, successful rival of Donatello, in the gates (1401) to the baptistry of San Giovanni, has immortalized himself by that work, which, from the eulogy bestowed on it by Michael Angelo, bears the appellation of the "Gates of Paradise." This undertaking occupied forty years of his life, and still, notwithstanding the criticism of Reynolds, remains one of the noblest monuments of modern art. The subjects are from the Old and New Testaments; and the complaint of Reynolds is, that "the landscape and buildings occupy so large a portion of the compartments that the figures remained but secondary objects, entirely contrary to the principle of the ancients." Brunelleschi, the intimate friend of Donatello, known better by his high acquirements as an architect, was not less a sculptor of considerable eminence: at Florence, in the church of St. Maria Novella, is an admirable crucifix by him in wood. In

1450, Andrea Verrocchio and Dominico Ghirlandaio were found amongst the first rank of sculptors in Florence. The former of these two, the master of Pietro Perugino and Leonardo da Vinci, executed at Venice the famous figure of Bartolomeo Cogleone da Bergamo on horseback. The latter was the master of Michael Angelo da Buonarotti, whom we have once more (*see* ARCHITECTURE and PAINTING) to introduce to the reader's notice as the most eminent of modern sculptors, as well as of architects and painters. The miraculous works of this extraordinary man seem rather the result of inspiration than of genius, and with him is introduced

The *third epoch*, in which the perfect restoration of the art was accomplished. The historian of the painters, sculptors, and architects wrote the life of Buonarotti while he was yet living, and thus apostrophises for his so doing: — "Let none be surprised that I have here written the life of Michael Angelo, who is yet living. Indeed it cannot be expected that he will ever die, and therefore it has appeared to me proper to do him this little honour; for when in common with other men his life shall pass away, he will be immortal in his immortal works, the fame of which, as long as the world lasts, will live with glory in the mouths of men and in their records, in contempt of envy and despite of death." Michael Angelo was nobly descended, and at the early age of 15 was patronized by Lorenzo de Medici, who took him into his house, and whilst living continued his friend. His career in sculpture was commenced by a sleeping Cupid, a Bacchus, and young fawn, the colossal David, and a group of a Madonna sitting with the dead Christ on her knees; works which raised him immediately above his cotemporaries. It is not our purpose here to touch upon the productions of Michael Angelo in the other two arts which occupied a great portion of his time, and which it appears he afterwards regretted; for Condivi, his biographer, observes, "Che mi rammenta udirlo dire che quando la, (the basso-relievo of the battle of Hercules with the Centaurs,) viede, cognosce quanto torto egli abbia fatto alla natura a non seguitar prontamente l'arte della scultura." Julius II. on being raised to the papal chair employed Michael Angelo on a mausoleum, which it was intended to place under the centre of the dome of St. Peter's. It was projected on a most magnificent scale; but being subjected to many delays, and the pope dying, only one of its sides was completed, which was afterwards erected in the church of St. Pietro in Vincolâ by order of his nephew. In this monument is found the celebrated Moses and some other statues, two of which in the present day are in the gallery at the Louvre. It is mortifying to know that a large portion of this artist's time was wasted at the quarries of Pietra Santa, owing to the misconduct of the underlings of Leo X. Cardinal Giuliano di Medici, in 1523, engaged him on the sacristy and library of San Lorenzo. In the Capella dei Depositi, or sacristy, are the statues of Lorenzo and Giuliano di Medici seated, and in Roman military habits: the former is conceived with a simplicity worthy of the highest era of Grecian art. The recumbent statues of Daybreak and Night, under the statue of Giuliano in the same chapel, "are grand and mysterious: the characters and forms bespeak the same mighty hand and mind evident throughout the ceiling of the Sistine Chapel and Last Judgment. Even this mighty master was doomed to experience ill-treatment from his employers, his last years having been attended with mortification, and chequered with vexation and trouble. Universal in his accomplishments, he was mainly useful in defending the city of Florence when it was besieged by the Prince of Orange. Having arrived at the advanced age of eighty, and withdrawn from all employment except the conduct of the works at St. Peter's, which he retained to prevent the intrigues for marring his design from being successful, he gratified the pious inclination of his mind, and derived amusement in his leisure hours from working on an enormous block of marble a group of four figures, consisting of the dead body of our Saviour, supported by Joseph of Arimathea attended by the two Marys; a composition of infinite grandeur and pathos, which he lived not to finish. His death occurred on the 15th of December, 1563, almost 90 years of age. "Michel," says Ariosto, "piu che mortal, Angel divino." Besides the honour he conferred on seven popes by serving them, he was the friend of Solyman emperor of the Turks, Francis I. king of France, the emperor Charles V., the princes of the republic of Venice, those of Italy, particularly the duke of Tuscany, reigning at the time of his death. His body having been buried in the church of the Holy Apostles at Rome, where the pope meditated a magnificent tomb to his memory, was privately removed to Florence, where funeral obsequies were celebrated over it with every demonstration of pomp and splendour. The ceremony took place in the church Della Croce, attended by all the members of the Academy, the church being decorated for the occasion with a catafalco, and the choicest examples of painting and sculpture. The panegyric was pronounced by Benedetto Varchi. Flaxman, in his Tenth Lecture on Sculpture, closes his account of him thus: — "The character and works of Michael Angelo have been dwelt on at greater length, because, as his mental and bodily powers continued far beyond the usual date of human life, his diligence attained to so much greater perfection in the principles of art. Anatomy, the motion and perspective of the figure, the complication, grandeur, and harmony of his grouping, with the advantages and facility of execution in painting and sculpture, besides his mathematical and mechanical attainments in architecture and building, together with the many and prodigious works he accomplished, demonstrate how greatly he contributed to the restoration of art." After this epoch, or perhaps almost belonging to it, appeared Giovanni da Bologna, a sculptor of extraordinary merit, and eminent particularly for his works in bronze and marble. His Venus coming from the Bath is delicate and graceful; and the group of the Rape of the Sabines in the grand piazza at Florence is extremely well composed, and possesses a fine undulation of line. The Mercury he executed, rising to fly, is energetic and original. There are many small works extant by this artist. Benevento Cellini, one of the strangest and most eccentric fellows that ever existed in the world, appeared about this period. He was chiefly employed as a goldsmith and sculptor in metals; but was frequently employed on large figures and groups, of which the Perseus holding the head of Medusa in his left hand at Florence is a splendid instance of his talent. Other real disciples of the great Tuscan master were Raphael di Monte Lupo, his favourite pupil, who assisted in the execution of the two statues of the Virtues on each side of the Moses; Nicolo di Tribolo, who made the bronze gates of the cathedral at Bologna; Giovanni dell' Opera, who received that name from the prolific chisel he wielded; and Vincenzo Dante. Of his school also are Baccio Bandinelli, a man of considerable talent, but of course greatly inferior to Michael Angelo, though he set himself up as a rival and competitor; Baccio di Monte Lupo, who among his works executed the crucifix in the church of San Lorenzo; Andrea Contucci, a clever and occasionally successful imitator of Michael Angelo, and founder of the school of Loretto; Francesco Rustici, a pupil of Leonardo da Vinci, but whose works evince a devotion to the style of Michael Angelo Buonarotti, and who introduced it into France; and Jacopo Tatti, commonly called Sansovino, who was the head of the Venetian school of sculpture. As an architect he was an artist of surprising talents, as is manifest from his works at Verona; his sculpture, however, is deficient in purity, though not in richness of composition. His principal pupils were Danese Cattaneo and Alessandro Vittoria. The principles of the school were diffused through Italy, and were equally to be seen in Lombardy and Naples: in the latter city the principal masters were Marliano Nola and Girolamo St. Croce. At Milan were Agostino Busti and Guglielmo della Porta, whose reputation was raised by the statues executed by him on the tomb of Paul the Third at St. Peter's. These have been esteemed as among the best examples of modern sculpture. Torregiano, who also belongs to this period, was of a vagabond disposition, but a man of genius; he was invited over to England, where he wrought upon the tomb of Henry VII. at Westminster, for which he received the sum of 1000*l*. From Benvenisto Cellini we learn that he was handsome, but of consummate impudence, having the manner of a bravo more than of a sculptor; and to crown all, what with his strange gestures, shrill voice, and a certain trick of knitting his brows, he was enough to frighten any one who came in contact with him. When he quitted England he visited Spain, says Vasari, and, distinguishing himself by many clever works, had a commission in marble from the Duke d'Arcus of a Madonna and Christ of the size of life, with great assurances that he should be rewarded according to his merit. The duke being a grandee of the first class, the sculptor considered he should be proportionately rewarded. After considerable study and application the work was finished to his own satisfaction; whereon, with impatience to possess himself of the treasure, the duke forthwith sent for it, and to display his generosity to the greatest advantage, two of his servants were loaded with the money in payment for it. The bulk was pleasing in appearance to the artist; but upon being opened the bags were found to contain only brass maravedi, amounting to the trifling sum of thirty ducats. Vexation and disappointment roused the indignation of Torregiano, who, looking on the present more as an insult than a reward due to his merit, snatched up his mallet, and heedless of the perfect workmanship with which it had been finished, as well as the sacred character of the subject, broke it in pieces, and sent the lacqueys away with their load of brass to recount the tale to their master. The grandee, enraged at the merited indignity with which the artist had treated him, and it may be horrified at the sacrilegious nature of the act, presented him to the Inquisition as an infidel and a heretic. Torregiano pleaded the right of an author over a work of his own creation, but without success: he was condemned to lose his life. Torregiano baulked, however,

the holy office of its victim by starving himself to death in his prison. This occurred in 1522, at which time he was fifty years old. In England we also had Giovanni da Padua in the following reign.

Spain produced some celebrated sculptors in the 16th century, their first native artist being Berruguette, a pupil of Vasari and Buonarotti. Berruguette's disciple, Paul de Cespides, is reputed the greatest sculptor that Spain ever produced.

It does not appear that Germany produced any sculptors of eminence before the 17th century. But in France, Jacques d'Angoulème, who had been at Rome, where he had a competition even with Buonarotti; Jean Gougeon, who finished the Fountain of the Innocents at Paris in 1550, and was one of the victims in the massacre on St. Bartholomew's Day; Jean Cousin, whose works, though deficient in force and truth, yet exhibit much grace and delicacy; and German Pilon, whose detail is remarkable for its beauty,—are names that entitle that country to a high rank among the nations of Europe, in which all the works of sculpture that were produced are so many testimonies of the influence which the genius of Michael Angelo exerted over the arts.

At the commencement of the 17th century, Bernini, a native of Naples, born in 1598, raised himself to employment before unknown. Endowed with all the qualities necessary for becoming a great artist, and desirous of distinguishing himself by the foundation of a new school, he plunged into caprice and complexity, and preferring effect to simplicity, effaced all traces of the style which from the time of Buonarotti had prevailed in Europe. His draperies founded on the paintings of the Bolognese school, his affected style, the violent expression in which he delighted, are the marks of an ambitious artist, whose only aim was to be striking. He deluged Italy with his works, and corrupted it with his taste till his death in 1680. The most celebrated cotemporaries of Bernini were Alguardi and Fiammingo. The latter is much esteemed for his representations of youth, and particularly of infants. At Naples he executed a concert of cherubs, and two infants on a monument at Rome, which are his most admired works: the latter was particularly admired by Rubens, who says of it, "Nature rather than art appears to have sculptured them, and the marble is softened into life." Rusconi in Italy succeeded to Bernini, and was the artist most in request at the beginning of the 18th century. His greatest work was at St. Giovanni Laterano, where he was assisted by Monnot, Le Gros, Moraldi, Moratti, Ottoni, and Rossi, pupils of the preceding school. The further progress of sculpture seemed now impossible; in short, the art seemed to have departed, though men whose names are not worth recording, with all the pretensions of artists, still hovered about the scenes of its former glory.

In France, Anzirevalle Adrian, Della Bella, and Tacca, pupils of Giovanni da Bologna, occupy the interval up to the beginning of the reign of Louis XIV.—one extremely creditable to the French school. In the remaining period of that monarch's reign, the principal sculptors were Gerardon, born at Troyes in 1630, and Puget, born at Marseilles in 1622; the latter of whom, from his fiery and energetic style, received the appellation of the Michael Angelo of France. These two were the head of the school of the succeeding sculptors of France; among whom was Falconet, celebrated for his writings, and for the equestrian statue he executed at St. Petersburg of the Czar Peter. The unfortunate Louis XVI., previous to the Revolution, was a great patron of sculpture, and had projected a collection of statues of the most eminent characters of the country. Pigal, the sculptor of the day, had executed some of them before the dreadful period which stopped in France for a time the cultivation of the arts. The school of Pigal was of considerable extent and influence, Mouchy, Bocquet, Moette, Chaudet, and Lebrune being members of it, and continuing the art to within a generation of the present time. Cotemporary, or nearly so, with these in Germany, were Rauchmuller of Vienna, Schluter of Berlin, Millich, Bartel, and others; subsequent to whom are Ohnmacht, Sonnenschein, and Nahl, all sculptors of much reputation. Our knowledge of Spanish sculptors is so limited, from their reputation not travelling away from their own country, and in it indeed being little known, except in Madrid and the chief cities, where the principal employment for them is the decoration of churches, that we apprehend little interest would be created by an enumeration of them. In England, up to a late period, the most celebrated sculptors were foreigners. Cibber, Roubiliac, and Scheemacher had the sway; and monuments of their genius, especially of the second, are the pride of some of our churches. The art, however, seemed to be near its dissolution, when Antonio Canova, in 1787, revived in Rome the purity without which it is worthless. This justly admired artist was born in 1757 at Possagno, a village amidst the Asolani hills, at the foot of the Venetian Alps. Pietro, his father, and Pasino, his grandfather, were sculptors, whose labours were chiefly confined to the churches of the district. Deprived of his father when only three years of age, he was indebted to his grandfather for the early instruction and employment of the chisel, by which he acquired great mechanical dexterity. Attracting the notice of the patrician Giovanni Faliero, he was by him placed with Torretto, one of the best Venetian sculptors of that day. Toretto soon afterwards died, and young Antonio then studied under Toretto's nephew, Ferrari. But he soon broke through the trammels of the art as it was then practised; and the rapidity of his progress having induced his patron to find a more appropriate theatre for the exercise of his powers, the young artist was sent to Rome in December, 1780, soon after which time the Venetian government granted him a pension of 300 ducats for three years. At this period the fashionable sculptors of Rome were Agostino Penna, Pacili, Bracci, Sibilla, and others, whose productions are already forgotten; so that in the way of emulation Canova had little to excite his talents. Before the period had expired for which his pension was granted, the zeal of Volpato had been successful in procuring for him the commission to execute the monument of Clement XIV. (Ganganelli). Thus was afforded to the young sculptor an opportunity of exhibiting his powers to a public who were fortunately capable of appreciating his merit. Before the expiration of the 18th century he had produced an amazing quantity of works, at which time it was not the practice (one afterwards introduced by him) to employ inferior workmen to reduce the block to the last shape of the superficies. The enumeration of his works would occupy much more space than can be here assigned to them: they were generally deficient in energy, but abounding in grace and elegance; and in his monumental sculpture there is vast originality of invention, whilst it is free from extravagance. His females are voluptuous, but not offensively so; his execution of them exquisite. In the monument executed in memory of the archduchess Christina of Austria, there is a pathos in the composition, whose figures are linked together with the chain of nature, worthy the divine Raphael himself. Canova died at Venice on the 13th of October, 1822; and his remains were removed to his native place, in which he had erected, at his own expense, a splendid church. Albert Thorwaldsen, a cotemporary of Canova, but much his junior, a native of Denmark, has by his great, though irregular and erratic genius, raised himself to eminence in Rome as well as in his own country. His powers in basso-relievo are great; but in extending the principles of the art, we cannot assign to him a niche in the temple of fame by the side of the man whose merits we have just discussed.

In England the respectable artists, Bacon, Banks, and Nollekens, were followed by Flaxman,—a name honourable to the arts of this country. Intense feeling and simplicity characterize all his works; and in epic sculpture we think he very far surpassed Canova. He was born at York in 1755, and died in 1826. The lectures which he delivered as professor of sculpture at the Royal Academy have been published. In the present day we apprehend the sculpture of our country, supported as it is by the talents of Westmacott, Lough, Rennie, Chantrey, and many others, will bear comparison with those of any other country in Europe.

SCULPTURE, PRACTICE OF. What has been said under the article PRACTICE OF PAINTING, relative to anatomy, comparative anatomy, symmetry, invention, expression, and drapery, equally applies to the art of sculpture, and need not be here repeated. We shall, therefore, merely state the different methods practised in producing a work in this art.

A model as large as the intended figure or group is first made in clay. It is placed on a stand called the sculptor's easel; and the general form is got out with the hand and fingers, small box-wood tools being made use of to touch the parts that the fingers cannot reach. The clay is kept moist, to prevent its shrinking, till the model is completed. The model is then moulded in plaster of Paris, before it begins to dry, whence a matrix is formed, into which plaster is introduced; and the matrix being broken away from it, the model in clay is thus transferred into one of plaster. This becomes the standard from which the artist takes all the measurements for the figure he is about to execute. The block of marble and the model being now placed on stands, with a graduated rod, which moves on a frame perpendicular to it, and has a point attached to it which can be made to advance and recede at pleasure, certain prominent points are selected and marked in the model, and their distance measured on the frame longitudinally and vertically, and also the distance that the point on the rod is advanced or receded to touch a given point. This being found on the outside of the rough block, the particular point is drilled down to as great a distance as was measured in the model. This operation being repeated for a great number of points, the surface is worked away to all the several points found as above, till at last it begins to assume the general form of the model. As the sculptor

approaches the surface which is to be left when finished, more caution and finer tools become necessary, till at length it is brought into a state for his finishing touches. The process which we have described of bringing the shapeless block into something like the form it is ultimately to bear, and which is an operation purely mechanical, is performed by inferior workmen, by which the artist's labour and time are much spared. It is only with such a genius as Michael Angelo that the making a model could be dispensed with.

SCU'PPER. A hole in the ship's deck or side to carry off the rain, or water shipped.

SCU'RVY, *Scorbutus*. This disease, once so common in our navy, is now of very rare occurrence. It generally appears connected with debilitating causes, and especially unwholesome food, want of exercise, and by cold and moisture. It begins with indolence, sallow looks, and loss of strength and spirits; the gums become spongy, the teeth loose, the breath fœtid; eruptions appear on different parts of the body; and at length the patient sinks under general emaciation, diarrhœa, and hæmorrhages. In the prevention and cure of this disease, much is effected by attention to diet and cleanliness. Fresh vegetables, farinaceous substances, and brisk fermented liquors, good air and due exercise, are among the principal remedial means. Acids, and especially lemon juice, have been much extolled; but the researches of Dr. Steevens have rendered the propriety of acid diet somewhat doubtful.

SCU'TATE. (Lat. scutum, *a shield*.) In Zoology, when a surface is protected by large scales.

SCUTE'LLUM. (Lat. scutum.) A term used by Gærtner to denote the small cotyledon on the outside of the embryo of wheat, inserted a little lower down than the other more perfect cotyledon, which is pressed close to the albumen.

SCUTIBRA'NCHIANS, *Scutibranchiata*. (Lat. scutum; branchiæ, *gills*.) A name given by Cuvier to an order of hermaphrodite Gastropodous Mollusks, including those which have the gills covered with a shell in the form of a shield.

SCU'TIGERS, *Scutigera*. (Lat. scutum; gero, *I carry*.) The name of a genus of unequal-legged Chilopodous Myriapods, which frequent houses and outbuildings in the South of Europe, and prey upon insects, wood-lice, and other small creatures.

SCU'TIPEDS, *Scutipedes*. (Lat. scutum, *a shield*; pes, *a foot*.) The name given by Scopoli to one of the divisions in his binary system of ornithology, including those birds which have the anterior part of the leg covered with segments of unequal horny rings terminating on each side in a groove.

SCU'TTLE. An opening in the ship's side or deck to admit light or air, or for communication.

To scuttle the decks, implies to cut holes to let the water down from them into the hold, as in the case of shipping a heavy sea, or of fire.

To scuttle a vessel, is to cut a hole in her for the purpose of sinking her.

SCUTTLE-BUTT. A cask of water with a large hole in it placed for use in a ship.

SCU'TUM. (Lat.) The shield of the Roman heavy-armed legionaries: was made of wood, defended with plates of iron, and covered with leather. It was either oval (ovatum), or of semi-cylindrical shape (called imbricatum). Polybius appears to make the latter sort 4 feet long, and it is evident that it covered a great part of the body. In the centre was a boss of brass or iron, projecting from the shield. From this classical word is derived the modern term *esquire*, through the middle ages: Lat. scutiger, *shield-bearer*.

SCY'LLA. In Mythology, the daughter of Nisus, king of Megara, who threw herself into the sea for love of Minos, king of Crete, and was turned into a bird. Also a poetical monster, half man half dragon, who inhabited the coast of Italy opposite Charybdis, according to the well-known legend in the *Odyssey*. The modern town of Scilla stands near the cave dreaded by the early navigators as the habitation of this monster.

SCY'PHUS. (Gr. σκυφος, *a cup*.) The cup of a narcissus. Also, in Lichens, a cup-like dilatation of the podetium, bearing shields upon its margin.

SCY'TALE. (Gr. σκυτος, *a skin*.) An instrument used by the Lacedæmonians for the conveyance of secret instructions to their commanders. The construction of it was as follows:—When a general was sent out, a black rod was given him, while another of exactly similar dimensions was preserved at home. When instructions were to be sent out, a strip of parchment was wrapped round the rod, and on the folds the orders were written; which accordingly could not be interpreted unless the parchment were rolled on a similar rod.

SEA. In Geography, a part of the great ocean. *See* Ocean Tides.

Sea. The term used by sailors for a single wave, or for general agitation. In a *long sea*, the waves are distant; in a *short sea*, they are closer and more upright: a *cross sea* is composed of waves moving in different directions.

SEA ANEMONE. The name of a highly organized Polype of the genus *Actinia*.

SEA BOAT. A term applied by seamen to a vessel, as respects her qualities in bad weather.

SEA DEVIL. The seaman's name of a large cartilaginous fish of the Ray tribe, the type of the genus *Cephaloptera*, Cuvier; also applied to the angler (*Lophius piscatorius*, Linn.).

SEAL. (Lat. sigillum.) In Gem Sculpture, a stamp cut or sunk on stone, capable of yielding an impression to any soft substance. When a gem is selected for cutting, it is put into the hands of the lapidary to reduce it to shape and smoothness. It is then fixed with mastic to a piece of wood to serve as a handle, and the subject is sketched upon it with a copper point or a diamond. The tool is a lathe somewhat resembling a turning lathe, into the end of the spindle whereof points, knobs, or circles can be inserted. The gem is then applied to the end of one of these tools, according to the nature of the cutting required, wetted with diamond-dust and olive oil, and by frequent working the subject is wrought. Frequent impressions are of course taken during the progress, to show the excesses or defects. These, however, are not necessary in working cameos, because the prominences are obvious to the eye. The tools are soft iron or copper; and the powder of the ruby, or other hard stones, is often substituted for diamond powder.

Seal. In Zoology, the English name for a genus of Marine Carnivorous Mammiferous Quadrupeds, otherwise called *Phocidæ*. The variety of seals is very great, and they are found in vast numbers in the seas round Spitzbergen, and on the coasts of Labrador and Newfoundland. As it frequents the British shores, it is well known, and has been repeatedly described. Seals are principally hunted for their oil and skins. When taken in the spring of the year,—at which time they are fattest,—a full-grown seal will yield from 8 to 12 gallons of oil, and a small one from 4 to 5 gallons. The oil, when extracted before putrefaction has commenced, is beautifully transparent, free from smell, and not unpleasant in its taste. The skin, when tanned, is extensively employed in the making of shoes; and when dressed with the hair on, serves for the covering of trunks, &c. *See* Fisheries.

SEAL, GREAT. All charters, commissions, grants of land, franchise, liberties, &c., letters patent, and letters close, of the king, pass the great seal. The usual course is, that a grant, or letters patent, pass by bill; which is prepared by the attorney or solicitor general under warrant from the king. It is then subscribed at foot with the sign manual, and sealed with the privy signet. In this stage it is next, in some cases, taken directly to pass the great seal; in other cases, an extract of the bill is taken to the keeper of the privy seal, who makes out a writ or warrant thereupon to the chancery, where it passes the great seal. Then the sign manual is a warrant to the privy seal, and that to the great seal. There are, however, some grants which only pass through certain offices, as the Admiralty or Treasury, under the sign manual, requiring neither privy nor great seal. The keeper of the great seal has, by 5 Eliz. c. 18., the same place and jurisdiction as the lord chancellor of England: since that statute, therefore, both offices cannot exist at the same time in different persons, which was not unfrequently the case before.

SEALING-WAX. The wax used for sealing letters, legal instruments, &c. The best *red* sealing-wax is made by melting in a very gentle heat 48 parts of shell-lac with 19 of Venice turpentine and 1 of Peruvian balsam; 32 parts of the finest cinnabar, thoroughly levigated, are then stirred in, and the whole well mixed. When it has cooled down, it is either rolled into sticks, or shaped in brass moulds. The best *black* sealing-wax is a mixture of 60 parts of shell-lac and 30 of ivory black; it may be perfumed with a little Peru balsam or styrax. The earliest application of sealing-wax to its present use seems to have been made about the year 1553. The first printed account of it is said by Berzelius to have appeared in 1563. The great seals applied in tin boxes to certain legal documents are made of a mixture of 15 parts of Venice turpentine, 5 of olive oil, and 8 of wax melted together, and coloured with red lead.

SEAL, PRIVY. All charters, pardons, &c., which require the great seal, pass first through the hands of the keeper of the privy seal; and other instruments of less consequence pass the privy seal only. A warrant to issue money out of the king's coffers, under the privy seal, is sufficient. The keeper of the seal is now an officer of state, with the title Lord Privy Seal. By 2 W.4. c. 49. the offices of clerks of the signet and privy seal are to be abolished as soon as vacancies occur in them.

SEA'MAN. A man brought up to the sea, and capable of discharging the duties of that life. A complete seaman is called an *able seaman*, and is rated A. B.; one less competent, an *ordinary seaman*; and a man fresh from the shore, a *landsman*. The reader will find in the *Com. Dict.* full particulars respecting the enrolment, wages, and in short all the statistics of seamen.

SEAMS. The spaces between the edges of planks: these in a ship are caulked, and then covered with pitch.

SEAMS. In Geology, thin layers which separate thicker strata.

SEAMEW. A name for the gull. *See* LARUS.

SEARCH WARRANT, in Law, is granted by a justice of the peace, under 7 & 8 G. 4. c. 29., to search for goods stolen, or respecting which other offences specified in the act have been committed. The warrant is granted on the oath of a credible witness, that he has "reasonable cause to suspect" the goods to be in the possession and on the premises of a certain individual.

SEA SICKNESS. Nausea and retching, which attack most persons on first going to sea; sometimes continuing only a day or two, but often lasting the whole of a long voyage. The most effective antidote, or remedy, consists in lying in the horizontal position. In some persons its violence is prevented by small doses of opium, or by soda water, or saline draughts in the act of effervescence; liniments and plaisters containing opium applied to the pit of the stomach are also recommended, as mitigating, or even preventing, this most annoying malady. The violence of the attacks not only varies in different individuals at different times, but the same person who escapes in one voyage shall suffer severely in another. The cause of sea sickness is probably referable to the influence of the motion of the vessel upon the circulation of the blood: it has been compared to the sickness occasioned by swinging. For some ingenious observations upon this subject, see Dr. Wollaston's Croonian Lecture, in the *Philosophical Transactions* for 1810.

SEASONS. (Fr. saisons.) The four quarters of the year, — spring, summer, autumn, winter. The seasons are considered as beginning respectively when the sun enters the signs Aries, Cancer, Libra, and Capricorn; so that the *spring* season commences about the 21st of March, *summer* about the 22d of June, *autumn* about the 23d of September, and *winter* about the 23d of December.

SEA UNICORN. The name of the narwhal (*Monodon monoceros*, L.).

SEA URCHIN. The name generally applied to the different species of *Echinus*.

SEBA'CEOUS GLANDS. Small cuticular glands which secrete a greasy matter, serving to protect and soften the skin or cuticle.

SEBA'CIC ACID. One of the acids produced during the destructive distillation of fat.

SECA'LE. (Lat.) The ergot or clavus of rye. *See* ERGOT.

SE'CANT (Lat. seco, *I cut*), in Trigonometry, is a straight line drawn from the centre of a circle to one extremity of an arc, and produced until it meets the tangent to the other extremity. The secant of an arc is a third proportional to the cosine and the radius; hence, if the radius be taken as unit, the secant is the reciprocal of the cosine. *See* TRIGONOMETRY.

SECE'DERS. *See* BURGHERS.

SE'COND, in the Sexagesimal Arithmetic, is the 60th part of a minute, or *prime*. Thus a degree of a circle, and an hour of time, are each divided into 60 minutes, and each minute into 60 seconds. In the old treatises on astronomy, the seconds are sometimes denominated *second minutes* (minutæ secundæ); while the minutes, being the first division of the unit, are the *primes* (minutæ primæ). Following out the analogy, the sixtieth part of a second was called a *third;* but this term is not found in modern works. It was formerly usual to denote minutes and seconds, both of time and arc, by the characters ′ and ″; but these are now generally used only to indicate minutes and seconds of arc, those of time being indicated respectively by the abbreviations *m.* and *sec.*

SE'COND. In Music, a musical interval; being the difference between any sound and the next nearest, whether above or below it. It may be either major or minor.

SE'CONDARIES, or SECONDARY QUILLS. (*Secondariæ*, Linn.) The large feathers of the wing which arise from the bones of the antibrachium or fore-arm, and principally from the ulna, are so called.

SE'CONDARY CIRCLES, in Astronomy, are great circles of the sphere perpendicular to another great circle, which is regarded as the primary, and consequently passing through its poles. The secondaries of the ecliptic are the circles on which the latitudes of celestial objects are measured.

SE'CONDARY ROCKS or STRATA. A series of stratified rocks with certain characters, by which they are distinguished as a class from the *primary* rocks, which are beneath them, and from the *tertiary* rocks, which lie upon them. *See* GEOLOGY.

SE'COND COAT. In Architecture, either the finishing coat, as in laid and set, or in rendered and set; or it is the floating when the plaster is roughed in, floated, and set for paper.

SE'COND SIGHT (called in Gaelic Taischitaraugh; from taisch, *an unreal* or *shadowy appearance*). A well-known Highland superstition. In all ages the idea has prevailed that persons endowed with the power of divination did not only foretel by instinct, but had sometimes an actual and mysterious vision of distant or future events; as in the lines of Lucan, which describe the presages before the battle of Pharsalia:—

> Euganeo, si vera fides memorantibus, augur
> Colle sedens . . . .
> Venit summa dies, geritur res maxima, dixit:
> Impia concurrunt Pompeii et Cæsaris arma.

But the peculiarity of the Highland superstition seems to consist in this, that persons were supposed to be endowed with the faculty who were in no other respect feared or reverenced for their supernatural powers: it was regarded as a mere natural power, like superior sharpness of sight or hearing. The inhabitants of the Western Islands were thought to be peculiarly gifted with it. It could not be exerted at pleasure; the power came on the seer involuntarily, and often to his extreme terror and suffering. Nevertheless, certain rules were in fashion for the interpretation of the visions; such, for instance, as that mentioned by Sir W. Scott, that if a seer saw a figure with its back to him, on altering the position of his own plaid if the figure appeared with its plaid similarly arranged the vision regarded the seer himself. Martin, in his *Description of the Western Islands*, seems to have brought this superstition into notice in England. It is well known how Johnson undertook the defence of it, in his *Journey to the Western Islands;* but, in despite of evidence which neither Bacon, Boyle, nor Johnson were able to resist, the *taisch*, with all its visionary properties, seems to be now universally abandoned to the use of poetry. The exquisitely beautiful poem of *Lochiel* will at once occur to the recollection of every reader. (Notes to the *Lady of the Lake*.) It is finely described by Collins in his ode on the *Superstitions of the Highlands*. But the classical bard of the second sight is Sir Walter Scott. (See especially his noble ballad *Lord Ronald*, the character of Allan Macalister in the *Legend of Montrose*, &c. &c.) How far the belief in second sight is preserved at the present day, we cannot tell. Mr. Logan, in his *Scottish Gael*, only says, "It is not so prevalent as formerly." (Vol. ii. 340.)

SE'CRETARY. An officer employed in writing letters, despatches, &c., under the orders of his superior. The title of secretary was first used to denote a public minister in France, where the three clerks of the privy council were also termed secretaries as early as the 14th century.

SE'CRETARY, LORD. A high officer in the kingdom of Scotland, resembling the great prothonotary in foreign courts. This office was kept up after the Union, but has been disused since 1746.

SE'CRETARY OF STATE. One of the highest officers of the British crown. This office, however, is comparatively modern in point of importance; the secretary of state having been originally what his name implies, a mere servant of the privy council. There was only one until the reign of Henry VIII., who added another; but their functions were limited to preparing business for the council board, which they attended afterwards with their proposals. Under Elizabeth, they became members of the council. Queen Anne raised the number to three, by the appointment of a secretary for Scotch affairs, — an office which did not long continue; and one for the American department was appointed in the reign of George III., but abolished in 1782. At present there are three secretaries of state. 1. The Secretary for the Home Department. 2. The Colonial Secretary. 3. The Secretary for Foreign Affairs. In each of these departments there are two under-secretaries, one of whom remains in office on a change of ministry. The clerks in the Home Office are divided into senior and junior; but no such distinction obtains in the other two. Each of the principal secretaries has 6000*l.* a year. The Alien Office is annexed to the Home Department: the State Paper Office belongs alike to those of all the departments. The Secretary for Home Affairs has the custody of the privy signet; and the Privy Signet Office, in which grants, letters, &c., sealed with the privy signet, are made out, is in his department. The principal secretaries are always ex officio cabinet ministers. Their position in the English government is, in fact, identical with that of the ministers of home and foreign affairs, &c., in France and other Continental countries. The Secretary at War is attached to the War Office. His salary is 2480*l.*; and he is also frequently, though not always, a member of the cabinet. The secretary of state for Ireland is also keeper of the privy seal of that part of the kingdom, and chief secretary of the lord lieutenant. His office is divided into two departments, military and civil, in each of which an under-secretary is placed. Like the secretary at war, he is, though more rarely, sometimes a member of the cabinet.

SECRE'TION. (Lat. secretio.) The process by which substances are separated from the blood in animals, or from the sap of vegetables.

In some cases a secretion appears to be a mere separation of water, and of other substances held in solution by it, from the blood; but in others the process is much more elaborate and intricate. A highly complicated glandular structure is requisite; and the proximate or ultimate elements of the blood are arranged into new combinations, so as to constitute a new and distinct product, of which no traces are to be found in the healthy blood. The animal secretions are arranged by Bostock under the heads aqueous, albuminous, mucous, gelatinous, fibrinous, oleaginous, resinous, and saline. Magendie's classification of the secretions comprises, 1. Exhalations, as from the skin, the surfaces of the closed cavities of the body, and the lungs; 2. Follicular secretions, which are either cutaneous or mucous; and, 3. Glandular secretions, such as milk, bile, urine, saliva, &c. *See* PHYSIOLOGY and BOTANY, &c.

SECT. A term used in ordinary language to signify any body which separates from the established religion of a country. In this sense, the word appears to be derived from Lat. seco, *I cut;* sectarians being, as it were, *cut off* from the general mass. But, on the other hand, the term was anciently applied to the *followers* of some distinguished person; in which sense, the idea of *cutting off* wholly disappears, and the word then seems to be derived from Lat. sequor, *I follow*. The chief sects, both of philosophers and religions, will be found noticed under their respective heads.

SE'CTION (Lat. sectio.), in Geometry, denotes the line formed by the intersection of two surfaces, and likewise the surface formed when a solid body is cut by a plane. When a plane is cut by a plane, the section is a straight line; when a sphere is cut by a plane the section is a circle; and when a cone is cut by a plane, the section may be a triangle, a circle, an ellipse, an hyperbola, or a parabola, which five figures are consequently called the *conic sections*. (*See* CONIC SECTIONS.) Vieta gave the name of *angular sections* to the branch of analysis which has for its object the investigation of the sines and chords of the multiples and submultiples of a given arc. On this subject the student may consult the work of Poinsot, entitled *Recherches sur l'Analyse des Sections Angulaires*, Paris, 1825. — *Section of a Ratio*, and *Section of a Space*, are terms that were employed by Apollonius of Perga, who wrote two books with those titles; the former of which was restored by Dr. Halley, and the latter by Willebrord Snell.

SECTION. In Architecture, the projection or geometrical representation of a building, supposed to be cut through, so as to exhibit its interior.

SE'CTOR. (Lat.) In Geometry, the *sector of a circle* is a portion of the area of the circle bounded by two radii and the intercepted arc. Sectors of different circles are said to be *similar* when the sides or radii include equal angles. The area of a sector is equal to that of a triangle whose base is equal to the length of the contained arc, and altitude equal to the radius of the circle.

SECTOR. A mathematical instrument, of considerable use in making diagrams, laying down plans, &c. Its principal advantage consists in the facility with which it gives a graphical determination of proportional quantities; and hence it is called by the French *the compass of proportion*.

The instrument consists of two rulers (generally of brass or ivory), representing the radii of a circular arc, and moveable round a joint, the middle of which forms the centre of the circle. From this centre there are drawn on the faces of the rulers various scales; the choice of which, and the order of their arrangement, may be determined by a consideration of the uses for which the instrument is chiefly intended. The scales usually put on sectors are of two kinds, — single and double; that is to say, such as are drawn only on one of the limbs, and such as are drawn on both limbs. The first kind, however (comprising, for example, a line of inches, of chords, sines, logarithms, &c.), are not peculiar to the sector, but are merely placed there for convenience, and may be used whether the instrument is shut or open. Of the lines repeated on both limbs the principal are the following: — 1. A line of equal parts, by which, with a pair of compasses, we are enabled, on the principle that similar triangles have their homologous sides proportional, to find a third proportional to two given lines, a fourth proportional to three given lines, to diminish a line in any given proportion, &c. 2. A scale of chords, which enables us to protract an angle of any given number of degrees, to find the degrees which any given angle contains, to cut off an arc of any magnitude from the circumference of a given circle, &c. 3. Scales of sines, tangents, and secants, whereby the lengths of those trigonometrical lines corresponding to a given arc of a circle of any radius are determined. 4. A line of polygons, whereby the proportional length of the side of any regular polygon (of not more than twelve sides) to the radius of the circumscribing circle is found.

The sector may be used in trigonometry for obtaining a rough solution of all the cases of right-angled plane triangles; and it is also conveniently applied to the construction of various geometrical problems. For a description of its different uses, see *Robertson's Treatise of such Mathematical Instruments as are usually put into a Portable Case*.

SECTOR. In Astronomy, an instrument constructed for the purpose of determining with great accuracy the zenith distances of stars passing within a few degrees of the zenith, where the effect of refraction is small. *See* ZENITH SECTOR.

SE'CULAR EQUATION, SECULAR INEQUALITY. (Lat. seculum, *a century*.) In Astronomy, any deviation from the mean motion or mean orbit of a celestial body is called an *inequality*, and the numerical expression of the magnitude and period of the inequality is called an *equation*. The equations representing the motions of the bodies of the solar system are of two kinds, *periodic* and *secular:* the first being those which pass through all their changes and return to the same state in a comparatively short period of time; and the second such as change their values so slowly that the variation only becomes sensible after the lapse of centuries, and require for the accomplishment of the series of their changes a length of time which in some cases astronomers have not yet ventured to calculate. Thus the lunar *evection*, which depends on the position of the transverse axis of the moon's orbit in respect of the line of the syzygies, is a *periodic* inequality, passing through all its different values in about 31 days 19½ hours; but the acceleration of the moon's mean motion, depending on a slow variation of the eccentricity of the earth's orbit, is a *secular* inequality, amounting only to about 10 seconds in a century. The secular inequalities are in fact periodic as well as the others; but they proceed so slowly that the observations of many hundreds, or even thousands of years, would be insufficient to make known their periodicity. The discovery of their true nature is one of the results of the theory of gravitation.

SE'CULAR GAMES, in Antiquity, were games celebrated once in a hundred years. They lasted three days and three nights, during which period sacrifices were offered up, and theatrical shows exhibited, and combats in the circus, &c. took place. Valerius Publicola, the first consul created after the expulsion of the kings, A. U. C. 245, was the first who celebrated them at Rome. Some authors maintain that the *seculum*, or age, consisted of 100, and others of 110 years; but it is certain several Roman emperors did not allow so long an interval as either period to elapse. Thus, Augustus celebrated secular games A. U. 736, Caligula 64 years later, and Domitian 26 years afterwards; on which occasion Tacitus assisted in the capacity of juris-decemvir. According to Zosimus, the emperor Septimus Severus was the last who celebrated them; but other writers have stated that under the emperor Philip, A. U. 1000, these games were held with more magnificence than had ever been before witnessed. They were celebrated, in all, eight times.

The original sæculum of the Etruscan augurs is said by some to have been measured by the longest life of those who were born at its commencement; and they had a peculiar tradition, that the duration allotted to nations was measured by a certain number of these sæcula. (Plutarch, *Sylla;* Censorinus, *De die Natali*.)

SECULARIZA'TION. In Politics, the appropriation of church property to secular uses. In most European states such appropriations have taken place on a great scale within the last century. In England, the only great secularization has been that made under Henry VIII.

SE'CULAR POEMS, in Antiquity, were those recited at the celebration of the secular games. Of this species of poem the Sapphic Ode of Horace, at the end of his book of *Epods*, is a noble specimen. Several editions of Horace give the name *secular poem* to the 21st Ode of the first book. (See *Niebuhr's Rome*, 2d edition, p. 288.)

SECULAR REFRIGERATION. The periodical cooling and consequent consolidation of the crust of the globe: a term used by geologists in reference to the supposed central heat, and even fluidity of the globe, and to the phenomena of its gradual refrigeration.

SECULAR YEAR. The same with Jubilee, — kept once in a century.

SECU'NDINE. (Lat. secundus.) In Botany, the outermost but one of the enclosing sacs of the ovulum, immediately reposing upon the primine. Mirbel considers it the second integument formed by the ovule; Schleider says it is the first, and that the primine or first integument of Mirbel is formed afterwards.

In Zoology, the fœtal membranes collectively are sometimes termed *secundines*.

SECU'RIFERS, *Securiferi*. (Lat. securis, *a hatchet;* fero, *I bear*.) The name of a tribe of *Terebrantia*, or boring Hymenopterous insects, comprising those in which the females have a saw-shaped or hatchet-shaped terebra or appendage to the posterior part of the abdomen, for the purpose of preparing a place to receive the eggs, and of depositing them therein.

SECU'RIPALPS, *Securipalpi.* (Lat. securis, *a hatchet;* palpo, *I feel.*) The name of a family of Coleopterous insects, comprehending those in which the maxillary palps terminate in a joint which is elongated and hatchet-shaped.

SE'DATIVES. (Lat. sedo, *I assuage.*) Medicines which assuage pain; generally by inducing sleep and diminishing irritability.

SE'DENTARIES, *Sedentaria.* (Lat. sedeo, *I sit.*) The name of a section of spiders (*Araneidæ*), comprehending those which remain motionless in the hiding-place of their web until called forth by an entangled prey.

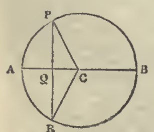
SEDGE BIRD. The name of the *Sylvia phragmitis*, Bech. This species of warbler visits this country about the middle of April, and emigrates in September. It frequents the sedgy banks of rivers, and constructs a nest composed of a little moss intermixed with dry stalks, lined with dry grass, and occasionally a few hairs. It lays five or six eggs of a light brown colour, mottled with darker shades of the same. It is sometimes called *reed bunting.*

SEDI'TION. (Lat. se, *apart*, and ire, *to go.*) In Law, a general and not strictly technical word, comprising, in common language, offences against the state which do not amount to high treason. The distinction between the two offences was not very accurately adhered to or defined until later times. Sedition is of the like tendency with treason, but without the *overt acts* which are essential to the latter. Thus, there are seditious assemblies, seditious libels, &c., as well as direct or indirect threats and acts amounting to sedition; all punishable as misdemeanours. The acts 39 G. 3. c. 79. (by which the famous Corresponding Societies were suppressed) and 57 G. 3. c. 19. were passed to prevent seditious meetings and assemblies.

SEE. (Lat. sedes, *a seat.*) The name usually given to the diocese of a bishop in England. It was originally applied exclusively to the papal chair at Rome; but it has long been used in its present wide signification.

SEED, is the reproductive part of a plant resulting from impregnation, and containing the embryo or rudiment of a future plant; or, in other words, it is the ovulum in its most perfect and finally organized state. It is a form of reproductive matter peculiar to flowering plants, its equivalent in flowerless plants being the spore. It is commonly said that as the seed is the part intended by nature to multiply the races of plants, special contrivances are provided for ensuring its dispersion and migration from place to place; such, for instance, as being discharged with force by the sudden explosion of the case or seed-vessel in which it is generated, having membranous wings that render it buoyant, and so on. But this idea, although to a certain extent true, is frequently misapplied to seed-vessels, as in the instance of the dandelion, the ash tree, the sycamore, &c.: in these latter cases the part to which the name of seed is given is a true pericarp or seed-vessel. On the other hand, many kinds of seed-vessels, such, for instance, as those of corn, of labiate and boraginaceous plants, &c., are miscalled seeds, or naked seeds.

SE'GMENT. (Lat.) In Geometry, a part cut off from a figure by a line or plane. The segment of a circle is a part of the area comprised between an arc and its chord; and segments of different circles are said to be *similar* when their arcs have the same ratio to the circumferences of their respective circles, or when they contain the same number of degrees. The area of a circular segment may be found as follows: — Let P R be the chord of a circle whose centre is C, and let A B be the diameter perpendicular to P R, and meeting it in Q; and put $x = $ A Q, $y = $ P Q, $z = $ A P, $r = $ A C the radius, and $\pi = 3{\cdot}14159$, the ratio of the circumference to the diameter. Now the area of the segment P A R is evidently equal to the difference between the sector A P C R and the triangle P C R; but the area of the sector $= r z$ (the radius into half the arc), and the triangle $= y\,(r - x)$; therefore the segment $= r z - r y + y z$. When the radius of the circle and the chord of the segment (that is, r and y) are known, this expression is easily calculated from a table of sines, for the angle A C P is found from its sine $= y \div r$; and when the angle is given the arc z is obtained from this proportion, $z : \pi r :: $ A C P : 180°. With respect to x, we have from the property of the circle $x = \surd(r^2 - y^2)$.



The superficial and solid contents of a segment of a sphere are found thus: — Let S be the spherical surface of the segment of the sphere whose centre is C by the plane P Q R. The symbols having the same values as above, the circumference of the circle P Q R is $2\,\pi\,y$; and the differential of the surface is $d\,$S $= 2\,\pi\,y\,d\,z$. But from the nature of the circle, $y\,d\,z = r\,d\,x$; hence $d\,$S $= 2\,\pi\,r\,d\,x$, and S $= 2\,\pi\,r\,x$; so that the surface of the segment is found in terms of the radius of the sphere and the altitude of the segment.

Let U denote the solid contents of the segment; then, since the area of the circle P Q R is $\pi\,y^2$, the differential of the segment is $d\,$U $= \pi y^2\,d\,x = 2\,\pi\,r\,x\,d\,x - \pi\,x^2\,d\,x$; whence U $= \pi\,x^2\,(r - \frac{1}{3}x)$.

SEGNO. (Ital. *a mark.*) In Music. *See* AL SEGNO.

SEGUE. (It. *it follows.*) In Music, a word which, prefixed to a part, denotes that it is immediately to follow the last note of the preceding movement. When minims, crotchets, &c. are subdivided by a stroke drawn through their tails, so as to make them into abbreviated groups, the term indicates that the following notes are divided similarly to those first marked.

SEIDLITZ WATER. The mineral water of Seidlitz, a village of Bohemia: sulphate of magnesia, sulphate of soda, and carbonic acid, are its active ingredients. It is often taken as an agreeable and effective aperient. The article sold under the name of *Seidlitz powders* is intended to produce the same effect, though very different in composition. These powders are generally sold in different-coloured papers: one blue, containing 2 drachms of the potassa-tartrate of soda mixed with 2 scruples of bicarbonate of soda; the other red, containing 35 grains of finely powdered tartaric acid. The former powder is dissolved in half a pint of water, and the latter in a separate wine-glass-full; the solutions are then mixed, and taken in the act of effervescence.

SEI'GNIORY. (Fr. seigneurie.) In Lower Canada, the right of feudal superiority in real estate. The term "fief" is applied both to the land held of a seigneur, and to the dominium directum, or right of direct seigniory, reserved to him who has granted the land in fief. The king has the paramount seigniory in all the feudal lands. By 6 G. 4. c. 59. persons holding fiefs or seigniories may on application to the king obtain a commutation and release of feudal burdens, and the fief or seigniory may be regranted in common socage. The land held in seigniory is said to amount to more than 15,000 square miles.

SEIGNORAGE. An ancient prerogative of the crown, whereby it claimed a per-centage upon every ingot of gold or silver brought to the mint to be coined. Upon gold it amounted under Edw. III. to 5*s.* per lb. weight, of which a fifth was appropriated to the master of the mint: upon silver it varied from 1*s.* to 1*s.* 3*d.* &c., but the amount varied in different reigns. The term *seignorage* is used in common language to signify *profit.*

SEI'SIN, in the Common Law of England, signifies possession, either actual (seisin in deed) or in law; as where lands have descended to a party who has not entered into actual possession of them, or is by wrong disseised of them.

SEISMO'METER. (Gr. σεισμος, *an earthquake.*) An instrument for measuring the shock of earthquakes and other concussions. (*Edin. Phil. Trans.* vol. xv. p. 219.)

SE'JANT. In Heraldry, a term employed to describe beasts when represented in a sitting posture. *Sejant-rampant*, sitting with the two fore feet lifted up, &c.

SELA'CIANS, *Selacii.* (Gr. σελαχος, *a species of scaleless fish.*) The name given by Cuvier to the tribe of Chondropterygians which includes the rays and sharks.

SELE'NE. (Gr. *the moon.*) In Grecian Mythology, the goddess of the moon. Her Latin equivalent was *Luna.* She was represented sometimes as the wife, the sister, and the daughter of Helios, the sun; and was identical with Artemis or Diana, which see.

SELENITE. (Gr. σεληνιτης.) One of the mineralogical synonyms of crystallized sulphate of lime.

SELE'NIUM. (Gr. Σεληνη, *the moon.*) A substance discovered in 1818 by Berzelius. In its general chemical habitudes it bears a resemblance to sulphur. It has hitherto been obtained in very small quantity, and generally occurs in some of the varieties of iron pyrites. It is a brittle opaque substance, tasteless, and inodorous; having something of the appearance of lead, but of a deep red colour when reduced to powder. Its specific gravity is about 4·3. At 212° it becomes soft and tenacious, and at 220° is perfectly liquid; at 650° it boils and sublimes. It is insoluble in water, and unaltered by air; and when heated by the blowpipe, so as to become oxidized, it exhales a strong odour of horse-radish. Its equivalent is about 40. It forms an oxide and two acids; the *selenious acid* being a compound of 1 equivalent of selenium and 2 of oxygen, and the *selenic acid* of 1 and 3. It also combines with hydrogen, forming the *hydroselenic acid*, a gaseous compound of 40 selenium + 1 hydrogen. Its odour at first resembles sulphuretted hydrogen, but it afterwards powerfully irritates the nose, excites catarrhal symptoms, and destroys the sense of smell. Dr. Prout has suggested the possibility of the evolution of this compound by volcanos, and its diffusion through the atmosphere as productive of certain forms of the epidemic disorder called influenza.

SELENO'GRAPHY. (Gr. Σεληνη, *the moon*, and γραφω, *I describe.*) The description of the surface of the moon, as geography is a description of the surface of the earth.

SELEU'CIDÆ, ERA OF THE. In Chronology, the era of the Seleucidæ, otherwise called the Macedonian era, dates from the epoch of the first conquests of Seleucus Nicator in Syria, about 311 years before Christ. It was followed generally by the Greek colonies bordering on the Levant; and by the Jews till the 15th century, by whom it was called the *era of contracts*. There is considerable difference of opinion among authors respecting the month and day on which the year of this era commenced, so that it is frequently not possible to fix the correspondence of dates; but according to the computation most generally followed, the year 312 of the era of the Seleucidæ began on the 1st of September in the Julian year preceding the first year of our era. Hence to reduce a Macedonian date to the common era, subtract 311 years and 4 months.

SE'LLA TURCICA. A cavity in the *sphenoid* bone; it is surrounded by the four clenoid processes, and contains the pituitary gland.

SE'LLI. The priests of Jupiter, who delivered his oracles at the sacred grove of Dodona in Epirus.

SE'LTERS or SELTZER WATER. A mineral water from Seltzer, about ten miles from Frankfort on the Maine. It is an agreeable beverage, from the quantity of free carbonic acid which it contains, and which covers its slightly saline taste. Common salt, with the carbonates of magnesia, lime, and soda, are the saline ingredients.

SE'LVAGE. A piece of very flexible kind of rope, composed of yarns not twisted together, but laid parallel, and confined by external marline

SE'MAPHORE. (Gr. σημα, *a sign*, and φερω, *I bear*.) A term mostly used synonymously with *telegraph*, but which, as its derivation imports, may be applied to any means whatever employed to communicate intelligence by signals. *See* TELEGRAPH.

SEME'. (Fr. *sown*.) In Heraldry, a term employed to describe a field or charge powdered or strewed over with figures, such as stars, billets, crosses, &c.

SEMEIO'TIC. (Gr. σημειον, *a sign*.) That which relates to the signs or symptoms of diseases.

SEMI-A'RIANS. A branch of the great Arian heresy, who denied the ὁμοούσιον, or *consubstantiality* of the Son with the Father; but admitted the ὁμοιούσιον, or *similarity of substance*. (*See* art. ARIANS; and Mosheim, *Eccl. Hist.* vol. i. trans. 1790, p. 44. *See* HOMOOUSIANS.)

SE'MIBREVE (*i. e.* half a breve). In Music, a note whose length is half that of a breve. It is the integer whose fractions and multiples express the time of other notes. *See* MUSIC.

SE'MICIRCLE. In Geometry, the half of a circle; or the figure bounded by the diameter and half the circumference.

SEMICO'LON. *See* PUNCTUATION.

SEMICU'BICAL PARABOLA. In Analysis, a curve of the second order: defined by this property, that the cubes of the ordinates are proportional to the squares of the corresponding abscissa; or by the equation $y^3 = a x^2$. The curve is the evolute of the common parabola.

SE'MIDIA'METER. In Geometry, half of the diameter; or the part of the diameter of any figure comprehended between the centre and the extremity of the diameter.

SEMIDIAPA'SON. (Gr.) In Music, a defective octave, or one diminished by a minor semitone.

SE'MIDIAPE'NTE. (Gr.) In Music, the same as *defective fifth*; which see.

SE'MIDIATE'SSARON. (Gr.) In Music, a defective fourth, properly called a *false fourth*.

SEMIDI'TONO. (Gr.) In Music, the same as a *minor third*.

SEMIME'TAL. A term applied by the old chemists to the brittle metals.

SE'MIMI'NIMA. In Music, a half minim or crotchet.

SE'MINYMPH. Lyonnet so calls the nymphs of those insects which undergo but slight changes in passing to the perfect or imago stage.

SEMIO'PAL. A silicious mineral nearly resembling the common opal.

SEMIPA'LMATE. (Lat. semi, *half*, and palma, *a palm*.) In Zoology, when the toes are connected together by a web extending along only their proximal half. The term *semi* being frequently used in the composition of zoological terms with the same meaning, it is only requisite to refer to the term to which it is prefixed.

SEMI-PELA'GIANS. A sect who differ from the Pelagians, from whom they are derived, in maintaining the necessity of the divine grace towards the practice of virtue; but at the same time conceive that this grace may be obtained by an effort of the human will. (*See* CALVINISTS, PELAGIANS, &c.; and Mosheim, *Eccl. Hist.* vol. ii. trans. 1790, p. 92.)

SE'MIQUA'DRATE, or SEMIQUARTILE. In the language of Astrology, an aspect of the planets when distant from each other half a right angle, or 45°. The terms *semiquintile* and *semisextile* have a similar meaning; the first denoting the *half of a fifth* of the complete circle, that is, 36°; and the second the *half of a sixth*, or 30°.

SE'MIQUAVER. In Music, a note whose duration is half that of a quaver.

SE'MISOSPI'RO. (It.) In Music, a small pause equal to the eighth part of a bar in common time.

SE'MITONE. (Gr.) In Music, the half of a tone; though, strictly speaking, that is not a proper definition of it, inasmuch as semitones are of three sorts, — greater, lesser, and natural. In keyed instruments which have their sounds fixed, the semitones afford the means of a new sort of scale between the different tones, by which their defects are partially remedied.

SEMIVO'WEL, is said of those consonants which, like vowels, can be pronounced independently, or without the aid of any other letter. To this class belong *b*, *d*, *c*, *g*, *k*, *p*, *s*, *t*, *v*, *x*, and *z*.

SEMO'NES, in Roman Classical Antiquity, were deities holding a middle place between the twelve supreme gods and heroes. To this class belonged such gods as Vertumnus, Priapus, the Fauns, Satyrs, &c. The word *semones* is a contraction of Lat. semi, *half*, and homo, *man*.

SEMU'NCIA. A small Roman coin, equivalent to half an ounce, being 1-24th of the Roman pound.

SENA'RIA. (Lat.) In ancient Architecture, the pipes of aqueducts, whose diameter was an inch and a half, or six quarters; when they were seven quarters they were called *septenaria*, and so on, according to the number of quarters of inches in their diameter.

SE'NATE. (Lat. senatus; i.e. *assembly of elders*.) The deliberative assembly of the Roman people. The members of this council were originally chosen from the patricians, and were probably single representatives of each of the houses of that order: a plebeian senator is first mentioned A. U. C. 355. At the foundation of the city their number was 100, which was doubled on the admission of the Sabines, and increased to 300 by Tarquinius Priscus; but the more ancient members and those admitted by this last king were distinguished by the titles of *patres majorum* and *patres minorum gentium*, or senators of the greater and of the lesser houses respectively. In the last ages of the republic the members of the senate amounted to above 400, and were still farther raised by the emperors to 1000. The members of the senate were originally chosen by the kings, and afterwards the election fell into the hands of the consuls, military tribunes, and finally of the censors; but the fact of having held certain magistracies, as the quæstorship, and all superior posts, gave a right to this privilege. Under the regal government the senate deliberated on such affairs as the king proposed to them, and he was said to act according to their counsel. On the establishment of the republic the whole power of the state was thrown into its hands, the different magistrates using the authority they enjoyed merely as its delegates. The first constitutional check imposed on it was the power of intercession, or negativing their proceedings, granted to the tribunes of the commonalty. Still while Rome was free the authority of the senate, though subordinate to the assembly of the people, remained very great. It assumed the guardianship of public religion; the management of the revenue; the appointment of governors to the provinces, whose constitution it settled; the direction of diplomatic affairs, and many other functions of importance. Under the emperors its power became, in general, little more than nominal; yet the assembly still existed till the occupation of Italy by the Goths in the 13th century after the foundation of Rome: and in the last ages of its existence, after the seat of empire had been transferred to Byzantium, it seems to have been the centre of what remained of the old national spirit. After that time its existence as a council ceased, though the name of senator was still retained by some noble families of Rome as an empty but high-sounding title. The senatorial badges were the laticlave or tunic with a purple band, black buskins reaching up to the middle of the leg, and a silver crescent on the foot.

The affairs of the Italian and provincial towns of the Roman empire, in imitation of the capital, were administered by senates. See as to these provincial senates, or curiæ, *Savigny's Hist. of the Roman Law*, vol. i.

SENATE. In many republican constitutions of modern times, the upper house of the national assembly has been so called. The senate of the United States (*see* CONGRESS) is composed of two members for each state of the Union. The senators are chosen by the state for six years. The American senate, besides its legislative functions, is also a species of executive council, assisting the president; its consent being necessary for the ratification of treaties, appointment of ambassadors, judges of the supreme court, heads of departments in the administration, &c. It is also the high court of impeachment for public functionaries.

SE'NEGA ROOT. The root of the *Polygala senega*. Rattlesnake root. It is brought from North America: it has a peculiar pungent flavour, and promotes the flow

of saliva. In large doses, it nauseates and purges. It is occasionally used in stimulating gargles; and in America, as an antidote,— probably a very inefficient one,— to the effects of the bite of the rattlesnake.

SE'NEGIN. The bitter acrid principle of the *Polygala senega*, or rattlesnake root.

SE'NESCHAL. A French title of office and dignity, derived from the middle ages, answering to that of steward, or high steward, in England. They were originally the lieutenants of the dukes and other great feudatories of the kingdom; sometimes termed baillis, or bailiffs. When the kings recovered the rights of suzerainty, and especially the judicial authority, in those provinces which had been previously governed by these great nobles, the bailiffs and seneschals continued as royal judges and superintendents, both military and financial; but their powers, like those of the dukes and counts whom they succeeded, were gradually encroached on by the crown.

SENNA LEAVES. The leaves of the *Cassia senna*. They are imported from Alexandria, whither they are brought from Upper Egypt. They are largely mixed with the leaves of the *Cynanchum oleafolium*, or *Argel*, which are thick, and not ribbed like the genuine senna leaves. They have a nauseous, mucilaginous, bitter taste, and yield a pale brownish green infusion. The true senna leaves are distinctly ribbed, thin, generally pointed, and when chewed have a peculiar nauseous flavour, and yield a dark brown infusion. It is a griping, nauseating, and somewhat drastic purge, and a most valuable addition to. or vehicle for, other purgatives.

SE'NSES. (Lat. sentio, *I feel.*) The faculties are so called by which we become acquainted with the properties and states of external things. They are five in number, — sight, hearing, taste, touch, and smell: for the physiology of which, the reader is referred to the articles; such as EYE, EAR, SMELL, &c. See also NERVOUS SYSTEM. We can only here advert to the fact, that the late Dr. Thomas Brown of Edinburgh and Sir C. Bell have propounded the novel doctrine of a sixth sense, called the *muscular* sense (our whole muscular frame being supposed to be a *distinct* organ of sense); — a doctrine which had almost fallen into oblivion, but to which Mr. Whewell has recently declared his adherence in his *Philosophy of the Inductive Sciences*, &c. This part of the subject is ably treated in the *Edin. Review*, vol. lxxiv.

SENSITIVE PLANT. This name is generally applied to a small annual, called *Mimosa pudica*, inhabiting the tropics of America. It has a stem about a foot and a half high, covered with stiff hairs; the leaves are bipinnate in a somewhat digitate manner; and the flowers are collected in small pink balls. It derives its name from the irritability of its leaves, which collapse and fold up when touched, or even when irritated by casting on them the focus of a burning glass; or by exposing them to the vapour of hydrocyanic acid. The cause of this irritability has been investigated by Dutrochet (*Mémoires pour servir à l'Hist. Anat. et Phys. des Végétaux, &c.* vol. i. 534.), who refers the phenomenon to the action of endosmose, and to the operation of a "fibrous tissue capable of moving inward under the influence of oxygenation." Without attempting to analyze the speculations of this author, which, however curious, can scarcely be said to throw much new light upon the subject, it will be sufficient to explain the nature of the phenomena themselves. When the leaf of a sensitive plant is at rest, it consists of many leaflets spreading flat, and connected in pairs along the sides of certain common leaf-stalks. When one of these leaflets is irritated, the pair to which it belongs rise upward, and apply their faces to each other; this is rapidly followed by the same action in the succeeding leaflets, and in the course of a few seconds the whole of the leaflets are in a state of collapse; then the leaf itself suddenly bends downwards; and if the plant is in very good health, the shock thus communicated to one leaf will extend to those immediately above and below it. After a time the leaf resumes its original position. Upon the approach of night, that is to say, upon the withdrawal of light, the leaf falls of itself into the same state, without any special irritation. This kind of irritability is by no means confined to the *Mimosa pudica;* on the contrary, some other species of the same genus, as the *M. dormiens, sensitiva, casta, somnians, palpitans*, &c. possess the same property, as is indicated by their names. And among the Leguminous order, it is also found beyond the genus *Mimosa*, as in the *Hedysarum gyrans*, whose three leaflets are in a continual state of dancing or balancing during the day. In fact the folding their leaves at night, which is universal in all the compound-leaved species of this order, is the same thing feebly exercised. Nor is such irritability confined to this order; the ternate and pinnate leaved species of *Oxalis*, the *Diandra muscipula*, and numerous other plants, exhibit similar phenomena.

SE'NSUALISM. In Mental Philosophy, that theory which resolves all our mental acts and intellectual powers into various modifications of mere sensation. The best known, and the most elaborate attempt of this kind which has been made in modern times, is that of Condillac, who conceived that he was following out the principles of Locke into their legitimate consequences. For this belief it cannot be denied that there exists at least plausible ground. Locke does indeed draw a distinction between sensation and reflection, as separate sources of "ideas;" but his account of reflection is so vague, and its existence apparently so unsupported in his system, as to justify the attempt to reduce it to mere revived sensation. The writings of Condillac may be regarded as a fair *reductio ad absurdum* of the theory which attempts to explain the existence of our mental phenomena independently of conditions in the mind itself. The theory opposed to sensualism is called *intellectualism.*

SE'NTENCE. In English Law, the decree or judgment of the ecclesiastical or admiralty courts is so termed; also, in popular language, the judgment of a criminal court allotting the punishment of a convicted person.

SE'NTRY. (Lat. sentio, *I perceive.*) The name given to a soldier when placed on guard. In all the countries of Europe, sentries are relieved every two hours.

SE'NZA (It. *without*), in Music, signifies without; as *senza stromenti*, without instruments; *con è senza violini*, with and without violins.

SE'PALS. The divisions of that portion of a flower called the *calyx*.

SE'PARATISTS. A religious sect which originated in Dublin about the year 1803. Their principle, like that of most sects at their commencement, was to return more nearly to what they conceived to be the primitive form of Christianity. There is nothing very peculiar in their tenets, beyond their withdrawal from the fellowship of other Christian bodies. In the year 1833 an act of parliament was passed for their relief in the matter of oaths.

SE'PARATISTS, or MOTAZALITES. The name of one of the chief heretical sects of the Mohammedans. They were the followers of Wasel Ebn Orta, who dissented from the main body of the Mohammedans about the 40th year of the Hegira. Their leading tenets consisted in rejecting the eternal attributes of God; in denying the great doctrine of predestination, so zealously cherished by all the orthodox Mussulmans; and in asserting the free agency of man. This sect is said to have been the first inventors of scholastic divinity, and are subdivided into several inferior sects, which mutually brand one another as infidels. (*Sale's Koran*, Preliminary Discourse, vol. i. p. 212.) The great opponents of the Separatists were the Sefatians, who maintained the eternal attributes of God (hence they were called *Sefati*, or Attributists); but who afterwards adopted a belief in the outward resemblance of God to created beings. This sect was afterwards subdivided into various sects, the chief of which were the Asharians, Moshabbehites, Keramians, Jabarians, and Morgians: for an account of which the reader is referred to the *Preliminary Discourse* above mentioned.

SE'PIA. In the Fine Arts, a species of pigment prepared from a black juice secreted by certain glands of the *sepia* or cuttlefish, which the animal ejects both to darken the water when it is pursued, and as a direct means of annoyance. That this juice was used as ink by the ancients is well known.

> Tunc queritur, crassus calamo quod pendeat humor,
> Nigra quod infusa vanescat *sepia* lympha;
> Dilutas queritur geminet quod fistula guttas.
>
> *Pers.* Sat. III.

Compare Pliny (*Nat. Hist.* l. ii. c. 29.), where he says that it was the property of this fish, when it was enclosed by a net, to shed a black juice, which so darkened the water that the fisherman could not see it. All the varieties of the sepia yield this juice; but the *Sepia officinalis*, which is so common in the Mediterranean, is chiefly sought after, from the profusion of colour which it affords. It is insoluble in water, but is extremely diffusible through it, and is very slowly deposited. When prepared with caustic lye, it forms a beautiful brown colour with a fine grain, and has given name to a species of drawing now extensively cultivated for landscapes and other branches of the fine arts. The honour of the invention of the sepic drawing is due to Professor Seidelmann of Dresden, who discovered it at Rome in 1777.

SE'PIADÆ. (Gr. σηπια.) Cuttle-fish tribe. The name of the family of Decapodous Dibranchiate Cephalopods of which the cuttle-fish (*Sepia officinalis*) is the type. They are characterized by the rudiment of a shell, in the form of a friable calcareous plate, imbedded in the back part of the mantle, and of which the material called *pounce* is made.

SE'PIOLA. (Dim. of sepia, *a cuttle-fish.*) The name of a genus of Decapodous Dibranchiate Cephalopods, of which the species are of small size, and are characterized by short, rounded, advanced subdorsal fins, and a short internal horny style.

SE'PIUM. The bone or internal shell of the cuttle-fish.

SE'POY. (A corruption of the Indian word sipahi, *soldier.*) The designation of the native troops in the service of the East India Company. They were so called as early as 1708 (see *Mill's British India*, book iv. ch. 1.), although at that period they do not seem to have been as yet disciplined in the European fashion, nor, indeed, until long after other European powers had set the example. (See the *United Service Journal* for 1836, vol. i. p. 461., where there is a valuable paper on the "History and Character of the Indian Army.") The first Sepoys (says the author) who were raised and regularly disciplined by the English, seem to have been carefully chosen either from among the Mohammedan portion of the population, or from among the higher castes of Hindoos, a considerable proportion of the latter being Rajpoots, the most warlike of Indian races. But the necessities of the service have subsequently introduced a greater mixture in their ranks. The character of the Sepoys as soldiers has been the subject of much discussion. According to a writer in the same periodical (1831, vol. iii. p. 3.), "the Sepoys have justly been celebrated for excellent qualities; as, for instance, patience and fortitude under difficulties and privations. But, on the other hand, if we analyze the account of the wars in which they have been employed, we shall find that they seem to possess passive rather than active courage; for instance, that in line they will remain steady under fire: in a broken or close country, however, where skirmishers and small detachments are necessarily most employed, they are found wanting." Others, however, disagree even from this modified dispraise. At all events, their fidelity and respect for their officers have generally been found of the highest and most durable character; the famous mutinies of Vellore in 1806, and Barrackpore in 1825, having been both, it is generally thought, provoked by the mismanagement of their superiors. Some, indeed, allege that these qualities received a severe shock in 1796, when a considerable alteration was made in the organization of the Indian army, and a larger proportion of British officers introduced, so that the internal economy of their battalions ceased to be superintended by their own "subadars." The Sepoys of Madras, says Sir J. Malcolm (*Quarterly Rev.* vol. xviii.), still remember with pride the campaigns of Clive and Coote, which are far beyond the memory of the present generation. The native Indian cannot rise higher than the rank of ensign, or cornet. The native cavalry is of more recent introduction, and seems scarcely to merit the praise of steadiness, which all agree in bestowing on the infantry. (See also *Williams's Indian Army;* Alison, *Hist. of the Revolution*, chap. li.; *Sir J. Malcolm's Political History of India*, vol. ii. chap. x.)

SEPS. (Lat. *a species of serpent.*) The name of a genus of Saurian reptiles, which have a long round serpentiform body, and four very short legs, each terminated in the common seps (*Seps chalcides*) by only three toes.

SEPTA'RIA. Nodules of indurated and slightly ferruginous marl, with interior fissures generally filled with some crystallized mineral, such as carbonate of lime, quartz, sulphate of baryta, &c.; thus dividing the section of the nodule into *septa*, or distinct partitions. When calcined and reduced to powder, these septaria furnish the valuable mortar called *Roman* or *Parker's cement*, which has the property of hardening under water.

SEPTE'MBER (Lat. septem, *seven*), so called from its being the seventh month in the Roman year as established by Romulus, which began with March, is the ninth month in the calendar of Numa. Several of the Roman emperors gave names to this month in honour of themselves; but, unlike the month of August, whose ancient name of Sextilis has been quite merged in that of Augustus, the name of September has outlived every other appellation.

SEPTE'MBRISTS. The name given to the agents in the dreadful massacre which took place in Paris on September 2. 1792, during the French Revolution. The numbers that perished in this massacre have been variously given; but the term has become proverbial throughout Europe for all that is bloodthirsty and malignant in human nature.

SEPTE'MVIRI EPULONUM. Certain priests in ancient Rome were so called, whose duty consisted in preparing the sacred feasts at games, processions, and on other solemn occasions. They were assistants to the *pontifices*, certain of whose privileges, such as the right of wearing the *toga prætexta*, they enjoyed. Their office was instituted A. U. C. 557; and at first they were only three in number, which was increased to seven, it is supposed, by Sylla.

SE'PTIC. (Gr. *σηπτος*, *putrid.*) A term applied by the old chemists and physiologists to certain substances supposed to promote putrefaction.

SEPTUAGE'SIMA. (Lat. *seventieth.*) In the Ecclesiastical Calendar, the third Sunday before Lent; the first Sunday in Lent being termed Quadragesima (fortieth), the three preceding ones Septuagesima, Sexagesima, and Quinquagesima.

SE'PTUAGINT. (Lat. *seventy.*) The Greek translation of the Old Testament made at Alexandria for the advantage of the Jews of Egypt, who had lost the use of the Hebrew language. According to the old tradition, this version was the work of seventy-two interpreters, who were shut up in separate cells by the command of Ptolemy Philadelphus, and there completed the whole translation alone, in which, upon examination, they were all found to agree to a letter; — a prodigy which established the inspiration of the work. It is supposed, however, by modern critics, that this version of the several books is the work not only of different hands, but of separate times; although the general design may have been that which we have mentioned. The authority of the Septuagint, as compared with the Hebrew text, from which it differs in many points, has been the subject of much controversy. It is from this version that the authenticity of the Apocrypha, which are not found in the Hebrew, is asserted by Roman Catholic writers. The quotations of the Old Testament which are found in the New are for the most part given in the words of the Septuagint. (See *Prideaux' Connection.*)

SE'PTUM. (Lat. *a partition.*) In Botany, any partition separating a body into two or more cells in a direction parallel with the longer axis. Partitions parallel with the shorter axis are called *phragmata*.

SEPTUM. In Anatomy the plate or wall which separates from each other two adjoining cavities; as the septum transversum, or diaphragm, between the chest and the abdomen; the septum narium, between the two nasal passages; the septum ventriculosum in the brain, and in the heart, &c. The partitions of chambered shells are also called *septa*.

SE'PULCHRE. *See* TOMB.

SE'PULCHRE, SAINT, HOSPITALLERS OF THE. An order of knighthood, originally instituted in Palestine, afterwards established in France by Louis VII., and united by Pope Innocent VIII. to that of Malta; but the order still continued to exist in France, and was taken under protection by Louis XVIII. in 1814.

SE'PULTURE, RITES OF (Lat. sepelio, *I bury*), signify literally the ceremonies performed in depositing the bodies of the dead *in the earth;* but the expression is applied in a more extended signification to all ceremonies of this kind, whether they consist in *interment*, *incremation*, or *embalming*. A veneration for the dead has characterized the history of every age and country; and the different kinds of funeral rites that prevail among different nations are intimately connected with their religious feelings, and form important testimonies at once of their modes of thinking and degrees of civilization. The three chief modes of treating the dead that have prevailed from the earliest ages down to the present times, are burning, interment, and embalming*; and all these modes were accompanied by ceremonies differing according to the genius or taste of the different people, but bearing, notwithstanding, such strong features of resemblance, as sufficiently to indicate the universality of the feeling which led to their adoption. The peculiar solemnities of the Greeks and Romans, among whom both incremation and interment prevailed, though the former was by far the most frequent, need not be detailed in this place. Among the Romans, the importance of burial to the dead may be gathered from the belief, that the souls of the unburied wandered a hundred years on the borders of the Styx before they were admitted to the infernal regions. The practice, peculiar to the Egyptians, of embalming their dead, has been noticed under MUMMY; and the custom still prevalent in India — which it may be truly said monopolizes the cruelties of funereal observances — of immolating women on the funeral pile of their husbands, will be found under SUTTEE. The practice of interment has been adopted by all the nations that have embraced Christianity. *See* CEMETERY.

SE'QUENCE. (Lat. sequentia.) In Music, a similar succession of chords ascending or descending diatonically.

SEQUESTRA'TION. In English Law, a species of execution for debt in the case of a beneficed clergyman, issued by the bishop of the diocese on the receipt of a writ to that effect. The profits of the benefice are paid over to the creditor until his claim is satisfied. *Sequestration* is also, in Chancery, the setting aside from both parties the matter in controversy.

SEQUESTRATION. In Scottish Law — 1. A species of diligence (*i. e.* a process), used where two or more creditors are in competition for the property of a land estate, the

* The singular usage adopted by the followers of Zoroaster, and still preserved in Thibet, is worthy of particular notice. From an idea that the pure elements of earth and fire would be contaminated by being made the instruments of dissolution, the corpse is laid upon a platform erected for the purpose, and enclosed with massy walls, and there abandoned as a prey to the wolves and the vultures. (*Schlegel's History of Literature.*)

owner of which is in insolvent circumstances; or where the right to a land estate is the subject of litigation. In these cases the court may, on application, sequestrate the rents, and employ a factor to collect them. 2. Sequestration is also the process whereby the whole estate, both heritable and moveable, of a bankrupt, is distributed equitably amongst his creditors. It is granted on application to the court of session by the bankrupt, with the concurrence of one or more creditors, or on their application, and on citation of the bankrupt; and is analogous to a fiat in bankruptcy in English law.

SE'QUIN. (Ital. zecchino; derived from zecca, *a mint.*) The gold pieces of Venice were originally so called; afterwards the name was extended to other gold coins in use in the Mediterranean, as those of the Pope, the Sultan, Florence, and Genoa. *See* MONEY.

SERA'GLIO. An Italian corruption of the oriental word *serai*. The palace of the Turkish sultan in Constantinople is thus designated by European writers. The principal gate of the seraglio is the Babi Humayun, or Sublime Gate, whence the ordinary title of the Turkish government is derived.

SE'RAPHIM, or JESUS, ORDER OF THE. An ancient Swedish order of knighthood, instituted in 1334; but dormant from the period of the Reformation until 1748. The number of knights, besides the king and members of the royal family, is limited to twenty-four.

SE'RAPHINE. A keyed musical wind instrument of the organ species, adapted to the size of a chamber.

SE'RAPHS, or SERAPHIM. (Heb. *to purify.*) In the Celestial Hierarchy, the angels of the highest rank. They are represented as surrounding the throne of God, whose messengers they are, and as being more immediately inspired with the Divine love, which they communicate to the inferior inhabitants of heaven. They are almost invariably spoken of in connection with the *cherubim*, whom they resemble both in rank and attributes.

SERA'PIS. An Egyptian deity. The image and worship of this god were brought from Sinope in Pontus to Alexandria, in the last year of Ptolemy Soter, in consequence, it is said, of a vision of Ptolemy I. According to some accounts, this image was a statue of Jupiter; but however this may have been, Serapis was clearly, as Sir G. Wilkinson expresses it (*Anc. Egypt.* iv. 360.), "at most a Græco-Egyptian deity." And there is no foundation for the notion entertained by some early Christian fathers, that he represented the Patriarch Joseph (which they supported by an argument drawn from the ornament in the shape of a bushel which the images of this god usually bore on the head); or for that of some modern antiquaries, that it was another name for Apis. (*Plut. de Is. et Osir. Quart. Rev.*, July, 1840.)

SE'RASQUIER. The name given by the Turks to the commanders-in-chief of their armies. It is compounded of two Persian words, signifying *head of an army.*

SERENA'DE (Span. serenata; from Lat. serenus, *clear*), signified originally music performed in the open air on a *serene* evening; but it is now universally applied to a musical performance made by gentlemen in a spirit of gallantry under the windows of ladies whom they admire. This practice, which was formerly very general in Spain and Italy, has latterly fallen greatly into disuse in these countries; but it is still very common in the German university towns, where the students are in the habit of assembling in the evening under the windows of a favourite professor, and offering him a musical tribute.

SERE'NE, SERENE HIGHNESS, SERENITY. (Germ. durchlaucht.) Titles of courtesy in European etiquette of considerable antiquity. Before the dissolution of the German empire, Serene and Most Serene Highness were the appropriate addresses of princely houses holding immediately of the empire. Since that period the rules of princely etiquette have become more uncertain; but it appears to be the general principle that these titles belong of right to members of the families of sovereign houses in the confederacy, and also to members of ci-devant sovereign houses *now mediatized;* and that sovereign princes can moreover concede these appellations to princes not sovereign within their own dominions, but not so as to give them a title to it out of them. But the distinctions as to the mode in which these titles are to be employed in addressing superiors, equals, and inferiors, are extremely complicated.

SERF. (Lat. servus.) The French name for the lowest class of slaves in the dark ages; those who were incapable of holding property, attached to the land, and liable to feudal services of the lowest description. In England this appears to have been the general character of the condition of the *villeins;* but in France and Germany Mr. Hallam thinks that the villeins, properly so called, were a superior class, only bound to fixed payments and duties in respect of their land. (*Middle Ages*, chap. ii. part 2. *See* VILLEIN.) The emancipation of this class in France was extremely gradual. Louis Hutin enfranchised them on the royal domains by edict in 1315; but it does not appear to have been carried immediately into execution, and a limited kind of servitude existed in some places down to the Revolution. The "serfs," or "gens de main morte," on some estates (*e.g.* in part of Champagne and Nivernois), could not leave their habitations, and might be followed by the lord in any part of France for the *taille*, or villein tax, which in some localities was not permanent, but *a volonté.* (See, as to the progress of enfranchisement, a memoir by Duprey, *Hist. Ac. I.* 38.)

SERGE. A cloth of quilted woollen, extensively manufactured in Devonshire and other English counties.

SERGEANT. *See* SERJEANT.

SE'RIES (Lat. *order*), in Arithmetic and Algebra, is a progression of numbers or quantities which succeed each other according to some determinate law. Thus, the progression of the natural numbers 1, 2, 3, 4, 5, &c. constitutes a series; the law of which is, that any term is greater by unity than the preceding. As the law which connects the terms may be varied in an infinite number of ways, it follows that series may have an infinite number of different forms: thus, an *arithmetical* series is one in which each term differs from the preceding by a constant number or quantity; a *geometrical* series is one in which each term is a multiple of the preceding by a constant factor.

The usual form of a series is a set of terms connected by the signs + or −. When the number of terms is greater than any assignable number, the series is said to be *infinite*.

A *converging series* is one in which the successive terms become less and less, each being smaller than that which immediately precedes it.

A *diverging series* is one in which any term is greater than the preceding.

A *recurring series* is one in which each term is a certain constant function of two or more of the preceding terms. Thus, $1 + 3x + 4x^2 + 7x^3 + 11x^4 +$ &c., is a recurring series, every term being formed in the same manner from the two immediately preceding. This series is formed by the expansion by division of the algebraic fraction $\frac{1 + 2x}{1 - x - x^2}$.

An *exponential series* is one whose terms depend on exponential quantities; a *logarithmic series* is one whose terms depend on logarithms; and a *circular series* one whose terms depend on circular functions, as sines, cosines, &c.

The *general term* of a series is a function of some indeterminate quantity x, which, on substituting successively the numbers 1, 2, 3, &c. for x, produces the terms of the series.

In general, the principal questions which arise respecting series are to find the sum of all the terms, or of a given number of them; and the exposition of the methods which have been invented for this purpose forms an extensive and important part of every treatise on the calculus. The student may be recommended in particular to Euler's *Introductio in Analysin Infinitorum*, and *Calculus Differentialis;* and the third volume of Lacroix's *Calcul Différentiel et Integral.*

SE'RJEANT. (Lat. serviens.) Serjeant-at-law is the highest degree in the common law, and all must proceed through this degree before attaining the dignity of judge. The Court of Common Pleas is open to serjeants only for the purpose of pleading. This exclusive privilege was attempted to be taken away in 1834, and for five years the court was thrown open. But after solemn argument, it was decided by the privy council that this enlargement was unwarranted; and the former practice again prevails. Serjeants-at-law are now made by the king's writ, commanding them to take their degree. No precise time seems now necessary to permit a barrister to become a serjeant. (See Serjeant Manning's learned work, *Serviens ad Legem.*)

SERJEANT. In the Army, a non-commissioned officer, both in infantry and cavalry regiments, whose duty it is to form the ranks and to instruct recruits in discipline. On parade they act as fuglemen, in going through the evolutions. The serjeant-major is a non-commissioned officer, who acts as assistant to the adjutant; but originally he was a field officer, corresponding in rank to the modern major. Colour-serjeants are certain non-commissioned officers appointed to attend the officers who have charge of the colours of the regiment.

SERJEANT, KING'S. One or more of the serjeants-at-law, whose presumed duty is to plead for the king in causes of a public nature, as indictments for treason, &c.

SE'RJEANTS-AT-ARMS. Officers whose duty is to attend the person of the king, the lord-high-steward when sitting in judgment on a traitor, &c. The whole number is restricted by an ancient law (13 R. 2.) to thirty. Two of these are allowed by the king to attend at the houses of parliament during their sittings, and each has a deputy. In the House of Lords, the practical maintenance of decorum below the bar, near the throne, and in the gallery, devolves upon the gentleman and

yeoman usher, with their assistants; so that "the serjeant-at-arms attending the House of Lords" has less conspicuous duties to perform than those which devolve upon "the serjeant attending the House of Commons:" both, however, execute the commands of the house to which they belong, as regards the apprehension or custody of all persons committed by order of parliament. In the House of Commons, the serjeant-at-arms is an officer of considerable importance, enjoying large emoluments, assisted by a deputy and several subordinate officers. During the sittings of the house he occupies a chair below the bar, and he directs a large proportion of the arrangements connected with the maintenance of order in the approaches to the house and the offices adjacent. He is at once the executive and the ceremonial officer of the lower house; but his discretionary powers are not extensive, for almost all his more important duties are performed under the immediate direction of the house itself, communicated through the speaker. The office is usually held by a gentleman of the military profession, seldom under the rank of a field officer.

SERJEANTY, GRAND AND PETTY. In English Law, feudal tenures. Tenure by grand serjeanty was where the tenant held land of the king by service, to be performed in his own person, in his wars, &c.; such as to bear a banner or spear, or to assist at his coronation. Tenure by petit serjeanty was where the owner was bound to contribute some small thing towards military service, &c.; such as a sword, dagger, bow, or spear. Tenure by grand serjeanty was preserved by stat. 12 C. 2., which abolished the other feudal tenures, and still subsists in some cases; as, for instance, the family of Dymoke hold the lands of Scrivelsby by the service of attending as champions at royal coronations.

SE'RMON. In Ecclesiastical usage. The use of the sermon or homily as a portion of the communion service is said to be of remote antiquity. This ancient custom fell into partial disuse during a great part of the middle ages. The Homilies of Elfric, archbishop of Canterbury in the 10th century, were long used in the English church; but these became antiquated; and in the year 1281, says Mr. Palmer (*Orig. Liturg.* vol. ii. ch. 4.), preaching seems to have been generally omitted. In that year Archbishop Peckham ordered, in his Constitutions, that four sermons should be delivered during the year. But for some time prior to the Reformation preaching was again coming more into use; and the publication of homilies by authority seems to have completely restored the ancient practice. *See* Homily.

SERON. A buffalo's hide, used for packing drugs and other articles.

SERO'SITY. (Lat. serum.) The liquid which exudes from the serum of the blood when it is coagulated by heat. It is water holding some of the salts of the blood and a trace of albumen in solution.

SE'RPENS, or SERPENS OPHIUCHI. In Astronomy, one of the ancient constellations in the northern hemisphere.

SERPENT. In Zoology, a general name for the species of the order *Ophidia*.

Serpents are divided into spurious, or *Pseudophidians*, and true, or *Ophidians* proper. The *Pseudophidians*, although presenting the well-marked external characters of the order, retain an imperfect pelvis, a small sternum, scapulæ, and coracoids or clavicles, hidden beneath the skin; whereby, as well as in the structure of the skull, they approach the Saurian order. The common blind-worm (*Anguis fragilis*) is a native representative of the *Pseudophidian* family.

The true serpents have neither sternum nor vestige of the scapular arch: they have no third eyelid, nor tympanum; but the auditory ossicle exists beneath the skin, and its handle passes behind the tympanic bone. Several species retain a vestige of hind-limbs, which in some even shows itself externally in the form of a small hook. The chief subdivisions of the true *Ophidians* are, — the *Amphisbænæ*; the *Tythlopes*; the *Roles* (*Tortrix*); the *Boas*; the *Pythons*; the *Colubers*; the *Acrochords*; — all which tribes are non-venomous. The *Pseudoboas*, *Rattlesnakes*, *Trigonocephali*, and *Vipers* are the venomous tribes; and are distinguished by having the superior maxillary bones short and moveable, supporting fewer teeth than in the non-venomous serpents, and having the first of the short series larger than the rest, sometimes the only conspicuous fang, and traversed by the duct of a poison-gland, around which duct the tooth is, as it were, longitudinally folded, so as to appear perforated by a canal. The last tribe of true serpents includes the *Hydrophides*, or sea-snakes, which have likewise a poison-gland and duct, the latter being inclosed by the first instead of the first of the maxillary series of teeth. The tail of the sea-snakes is flattened vertically, and forms their chief organ of swimming. No species of this family has yet been discovered which exceeds seven feet in length.

The remains of an extinct genus of serpents (*Palæophis*), indicating species of from ten to twenty feet in length, have been discovered in the Eocene tertiary formations in Suffolk, Kent, and Sussex. (See Mr. Owen's Paper in the *Geological Transactions*, 2d Series, vol. vi. p. 209.)

In antiquity the serpent played an important part. By some nations it was regarded as the emblem of cunning, deceit, and wickedness (compare the narration of the fall of man in Genesis with the Persian saga of Ahreman and Ormuzd); by others, such as the Egyptians and Phœnicians, it was looked upon as a good genius (αγαθοδαιμων), and worshipped as the emblem of fertility; while by the Greeks and Romans, whose mythology originated undoubtedly from Egypt and the East, it appeared under a variety of symbolic representations. With the latter the serpent was the well-known emblem of the healing art; and in the present time a serpent with its tail in its mouth is regarded as an emblem of eternity. The serpent appears also to have held a place in the Scandinavian mythology, where it was regarded as a symbol of the human passions. In the early ages of the Christian church, a sect of the Gnostics, also, worshipped the serpent, whence they were called Ophites (from Gr. οφις, *a serpent*). (See *Mosheim's Geschichte der Schlangenbrüder der ersten Kirche.*)

Serpent. (So called from its form.) A musical brass wind instrument, serving as bass to the horns or cornets. It is most generally covered with leather, and has three parts, — a mouth-piece, neck, and tail. The compass is two octaves, produced by six holes stopped with the fingers.

SERPENTA'RIUS. One of the ancient northern constellations, represented on the globes by the figure of a man grasping a serpent (*serpens*) in his hand. *See* Constellation.

SE'RPENTINE. A magnesian rock of various colours, and often speckled like a serpent's back. *See* Geology.

SERPI'GO. *See* Ringworm.

SERPU'LEANS, *Serpulea*. (Lat. serpo, *I creep*.) The name of a family of Cephalobranchiate Anellidans, inhabiting cylindrical and tortuous calcareous tubes; generally parasitic on shells.

SE'RRATE. (Lat. serra, *a saw*.) In Zoology, when a part is cut into teeth like a saw, or is armed with teeth whose sides are unequal.

SER'RICORNS, *Serricornes*. (Lat. serra, *a saw*; cornu, *a horn*.) The name of a family of Coleopterous insects, comprehending those which have serrated or saw-shaped antennæ.

SERTULA'RIA. (Lat. sertum, *a wreath*.) The name of a genus of compound tubular Polypes; restricted, in modern zoology, to those species in which the cells are arranged on two sides of the stem, either opposite or alternate.

SE'RUM. (Lat.) The fluid which separates from blood during its coagulation. *See* Blood.

SE'RVILE. A Spanish political nickname; applied, in the first instance, to those who opposed the changes advocated by the liberal party in the cortes of 1808 and the following years.

SE'RVITES. (Servants of the blessed Virgin.) A religious order, instituted in Tuscany in A. D. 1233, under the rule of St. Augustin. The monks wore a black habit, in commemoration of the widowhood of the Virgin. (*Mosheim*, cent. xiii. part 2.)

SERVITOR. (Lat.) An under graduate, who is partly supported by the college funds, is so called at Oxford. The servitors at Oxford are the same class as the sizars at Cambridge.

SE'RVITUDE, in the Civil Law, is divided into real or predial, mixed, and personal: the first being the subjection of an inheritable thing to certain duties or services towards another inheritable thing; the second, that of an inheritable thing towards a person; the third, that of a person towards a person or thing, *i. e.* slavery, whether by dependence on a person or on the soil. The word *servitude* is equally applicable to the duty or burden, and to the right of exacting it: *e. g.* the right of way which A. enjoys on the land of B., and B.'s liability to permit that right to be exercised, are both designated by the term *servitude*; the first active, the latter passive. Real servitudes are numerous, and fall into several classes or divisions. They are, for example, either *visible*, such as the right to light and air, sewers, &c.; or *latent*, such as the right of way, right of drawing water, &c., which appear only when they are exercised. They were also divided by the Romans into urban, which affected dwellings in the city; and rustic, appertaining to land and farm building. Of mixed servitudes only three species were recognized by their writers on jurisprudence, — usufruct, use, and habitation.

SE'SAMOID BONES. (Gr. σησαμη, *a seed or grain*, and ειδος, *form*.) Small bones found at the articulations of the great toes, and occasionally at the joints of the thumbs. Little tendinous ossifications are sometimes met with in other parts, especially in the advanced age of laborious persons.

SE'SAMUM. (Gr. σησαμον.) A genus of plants of the natural family *Pedalinæ*. They are supposed originally to have been natives of India; but are now cultivated in many countries. Their seeds, which are employed as an article of diet, and yield an oil of a very fine quality, form an extensive article of commerce in the East. All the species are annuals. The term *sesame* has long been familiar to all the readers of the *Arabian Nights' Entertainments*.

SE'SIA. (Gr. σης, *a moth*.) The name of a genus of Lepidopterous insects.

SE'SQUI (Lat.), applied to words, signifies one integer and a half; as sesqui granum, *a grain and a half*, &c. In Chemistry this term is used to designate compounds in which an equivalent and a half of one substance are combined with one of another; thus, sesquicarbonate of soda is a salt composed of one equivalent and a half of carbonic acid with one of soda.

Sesqui. In Music, a whole and a half; which, joined with *altera*, *terza*, *quarta*, &c., is much used in the Italian music to express a set of ratios, particularly the several species of triple time.

Sesqui. In Geometry, the expression of a ratio in which the greater term contains the less once, and leaving a certain aliquot part of the less over. Thus, if the part remaining is half the less term, the ratio is called *sesquialtera*; if the part remaining be a third of the less term (as in the ratio of 4 to 3), the ratio is called *sesquitertia*, and so on. These terms are nearly obsolete. *Sesquiduplicate*, however, sometimes occurs in modern treatises, and signifies the ratio in which the greater term is twice and a half times the less; as the ratio of 10 to 4, or of 15 to 6.

SE'SSILES, *Sessilia*. (Lat. sedeo, *I sit*.) The name of a division of the class *Cirripeds*, comprehending those species which are not suspended by a pedicle.

SE'SSION, COURT OF. The supreme civil court of Scotland, having jurisdiction in all civil questions, of whatever nature. It was constituted by an act of the Scottish parliament in 1537. It was intended to supply the place of the previously existing courts, and more especially of a judicial committee of parliament called the "lords of session;" whence the name of the court and the titles of the judges. Originally it consisted of seven laymen and eight churchmen, including the president. In 1640, however, an act was passed providing for the exclusion of churchmen from the court; and though repealed in 1661, the principle laid down in it has ever since been acted upon. Other important improvements were introduced at different periods, particularly after the Revolution, when the right of appeal from the court to parliament was, for the first time, recognized. At the Union power was given to all individuals who considered themselves aggrieved by judgments of the Court of Session to appeal to the H. of Lords; and it is a curious fact that at this moment, and for a lengthened period, the principal judicial business of the H. of Lords has consisted in hearing and deciding Scotch appeals. Originally, and down to 1808, the whole fifteen judges sat together in one court; but in that year an act was passed dividing the court into two chambers, the lord president presiding in the first division of seven judges, and the lord justice-clerk in the second of six; the two remaining judges trying cases in the first instance, or, as it is technically termed, sitting as lords-ordinary. Since then the number of judges has been reduced to thirteen; four belonging to each of the divisions, and five acting as lords-ordinary. The judges were at first chosen by the Scotch parliament; but since 1554 they have been appointed by the crown. They are either, as already stated, called lords of session, or senators of the college of justice; which last embraces the whole body of barristers (advocates) and attorneys or solicitors who practise before the court. They must be twenty-five years of age; and, by the Treaty of Union, no person can be named to the office unless he have served as an advocate or principal clerk of session for five years, or as a writer to the signet for ten. The salaries of the ordinary judges have recently been raised to 3000*l*. a year each; those of the lord justice-clerk and lord president being respectively 4000*l*. and 4500*l*.

At its outset the Court of Session was intended to serve as a standing or perpetual jury for the trial of cases; the introduction of petty juries into the trial of civil cases in Scotland being only of very recent date, as well as of limited application. It was, in fact, unknown till 1815, when a special or jury court was instituted, for the trial of cases involving questions as to the value of property, or damages, or the determination of some fact. But in 1830 this court was suppressed, and the Court of Session now avails itself of the assistance of petty juries in the trial of the above description of cases. *See* Justiciary, Court of.

SE'SSION OF PARLIAMENT. The period between its meeting and prorogation. All the acts passed in a session are legally considered as forming a single statute; each separate act being designated as a chapter, and its subdivisions as sections. *See* Parliament.

SESSIONS OF THE PEACE. In English Law, the term "Session of the Peace" is applied to designate a sitting of justices of the peace for the execution of those duties which are confided to them by their commission, and by charter or statute. Such are, — 1. A petty (or petit) session, which is a private meeting of two or more justices of the peace for the execution of some power vested in them by law; many acts of parliament requiring the concurrence of a plurality of justices, and there being other occasions on which, although not strictly necessary, it is considered usual and expedient. One of the most important instances of the first kind is the holding parties to bail against whom a charge of felony has been entertained. 2. A special session; which is principally distinguished from the former by being public, instead of on the private motion of the justices, it being necessary that notice should be given to every magistrate of the division. Special sessions are held to grant licences, execute the provisions of the Highway Act, appoint overseers of the poor, and for many other purposes. 3. Quarter sessions. (See that article; and see Justice of the Peace.)

SESTE'RTIUM. (Contracted from mille sestertiorum.) The sum of 1000 sestertii; usually estimated at about 8*l*. English.

SESTE'RTIUS. A sesterce; a Roman silver coin, equal in value to two *asses* and a half, or nearly twopence of English money.

SE'TA (Lat.), is a term used by botanists in various senses. It is the stalk that supports the theca, capsule, or sporangium of mosses; the awn or beard of grasses, when it proceeds from the extreme point of a palea or glume; sometimes the glandular aculeus of roses, and also the abortive stamens or rudimentary perianth of Cyperaceous plants.

SETA'CEOUS. (Lat. seta.) In Entomology, the antennæ which resemble a bristle are so called.

SET FAIR. In Architecture, the coat of plaster used after roughing in and floated, or pricked up and floated. It should be well trowelled, to answer well for colour.

SE'THIANS. In Ecclesiastical history, a sect of Christian heretics, who sprung up in Egypt in the second century, strongly imbued with the principles of Gnosticism; but whose chief peculiarity consisted in their belief in the identity of Jesus Christ with Seth, the son of Adam, whence they derived their name. They continued to exist about 200 years, during which period they had many followers.

SE'TICERS, *Seticera*. (Lat. seta, *a bristle*; Gr. κερας, *a horn*.) A term applied by Latreille to a family of Lophyropodous Crustaceans, including those in which the superior antennæ are long and setaceous.

SE'TIGERS, *Setigera*. (Lat. seta, *a bristle*; gero, *I carry*.) The name of a tribe of Anellidans, including those which, like the earthworm, are provided with bristles for progressive motion. The *Setigera* are the first tribe of the Abranchiated order of Anellidans.

SE'TIREMES. (Lat. seta, *a bristle*; remus, *an oar*.) A name given by Kirby to the natatory legs of certain aquatic insects, which are fringed with bristles.

SET OFF. In Law, a species of defence to a civil action, by which a party acknowledges the justice of the plaintiff's demand, but sets up a demand of his own against the plaintiff sufficient to counterbalance either the whole or a part of it.

SE'TON. (From Lat. seta, *a bristle*; because bristles or horse hairs were formerly used to keep open the wound.) A seton is an artificial ulcer, made by passing a skein of thread under a portion of the skin by means of an instrument called a seton needle: the thread is occasionally anointed with irritating substances, in order to keep up a discharge from the sore.

SETO'SE. (Lat. seta, *a bristle*.) In Zoology, when a surface is beset with stiff scattered hairs.

SE'TTING. In Architecture, the quality of hardening in plaster. Also the fixing of stones in walls or vaults.

SE'TTING COAT. In Architecture, the best sort of plastering on ceilings or walls; in inferior work it is made of *fine stuff*, and when the work is very dry a little sand is used. A setting coat may be either a second coat on laying or rendering, or a third upon floating. The term *finishing* denotes the third coat, where stucco is used; that of *setting*, where the work is for paper.

SE'TTLEMENT. In Law, the right which an individual acquires to parochial assistance, under the statutes for the relief of the poor, in that parish or district to which he legally belongs, and in which he is said to have the settlement.

The law of settlements has recently undergone considerable alterations by the Poor Laws Amendment Act 4 & 5 W. 4. cap. 76. But that act does not, except in certain cases, take away settlements already possessed by virtue of the law as it previously stood under a great variety of enactments. It is, consequently, necessary to consider in how many modes a settlement may now be legally acquired; and, also, what modes of settlement were recognized before the passing of the act in question

The first species of settlement is by birth; all persons who have not obtained a settlement elsewhere by other means being legally settled in the parish or district wherein they were born. Before the passing of the late act, bastard children were deemed to be settled in the parish where they were born: they now have, and follow, the settlement of their mother until they attain the age of sixteen, or acquire settlements in their own right. 2. Settlement by parentage. All legitimate children are settled in the parish where their parents are settled, until they become emancipated. Emancipation takes place on attaining the age of twenty-one, if living separate from the parents; or marriage; or gaining a settlement in the party's own right; or contracting some other relation inconsistent with the notion of a subordinate situation in the parental family. 3. Settlement by marriage. A woman acquires the settlement of her husband; and after his death she retains his last settlement, unless she acquires a new one for herself. 4. Settlement by apprenticeship. This is acquired by a person who has been bound an apprentice, and has inhabited, under such apprenticeship, in any town or parish; the place where he has resided the last forty days being that in which he is settled. Actual service with the master is not necessary; but if he have served elsewhere, it must be with the master's permission. Apprenticeship in the sea service or fishing trade does not, since the recent act, confer a settlement. 5. Settlement by renting a tenement. A person *bonâ fide* occupying and renting a tenement, at the rent of 10*l*. per annum at least, for the term of a year, the rent for a year having been actually paid (and the tenement having been actually occupied by him for a year also), acquires a settlement by dwelling forty days in the parish in which such tenement is situated. Since 4 & 5 W. 4., no settlement can now be acquired by renting a tenement, unless the person occupying it has been rated to and has paid the poor's rate for one year at least. 6. Settlement by estate. A person having, by descent or devise, &c., an estate in lands or tenements, either freehold, copyhold, or for years, acquires a settlement in the parish in which it is situate by forty days' residence. But no such settlement is acquired by the purchase of an estate, unless bought for 30*l*. at least, *bonâ fide* paid. And, by the late act, no person possessing such a power of acquiring a settlement shall retain it longer than he shall inhabit within ten miles of the parish. 7. Settlement by being charged with and paying parish taxes and levies in respect of a tenement of the value of 10*l*.; such as poor rate, church rate, or land tax. These are now the only modes of acquiring a settlement: but two more must be mentioned, by which a settlement could formerly be acquired, as the settlements so gained still continue in force. 1. By hiring and service. This could be obtained by any unmarried person lawfully hired into any parish or town for the space of a year, provided he continued in service under such hiring for the space of a year, and resided in the parish forty days. 2. By serving an office. This was obtained in any place by executing any public annual office.

Poor people coming from one parish to another, and endeavouring to settle themselves in the latter, may, if they become actually chargeable, be removed by an order of two justices to that in which they were last legally settled; and all persons who think themselves aggrieved by such order of removal (usually the parish to which the removal takes place) may appeal against such order to the next general or quarter sessions of the peace. It is doubtful, indeed, since the statute 4 & 5 W. 4., whether any but the parish can appeal. The parish appealing is bound to give sufficient notice of the intended appeal, and also (since the stat. 4 & 5 W. 4.) to state in writing the legal grounds on which the order is contested. The sessions must either quash or affirm the order of the justices; and the order of the sessions can only be quashed by the Court of King's Bench, either on a special case, granted by the sessions, for the reference of a point of law to the superior court, or on certiorari, for defects appearing on the face of the order.

A *certificate* is a written acknowledgment, by the churchwardens and overseers, that a particular person is legally settled in their parish. A certificate-man cannot gain a settlement in the parish to which the certificate is directed, except by renting a tenement of the annual value of 10*l*. *See* Poor Laws.

SE'TTLEMENT, ACT OF. In English History, the statute 12 & 13 W. 2. c. 2., by which the crown was limited to the Princess Sophia, duchess dowager of Hanover (youngest daughter of Elizabeth, queen of Bohemia, who was daughter to James I.), and the heirs of her body, being Protestants,—on the failure of issue of the Princess Anne, then next in succession. The duchess died in the reign of Queen Anne; and her son, George I., was consequently called to the throne.

SETT OFF. In Architecture, the horizontal projection left in carrying up a wall, where the thickness of it diminishes at its different stages or stories.

SE'VENTH. In Music, an interval; whereof there are four species. First, the defective seventh, consisting of three tones and three greater semitones. Second, the minor seventh, consisting of seven degrees and six intervals, diatonically taken; four being tones, and the rest greater semitones. Third, the major seventh, being only a major semitone less than the octave. Fourth, the extreme sharp seventh, which is only a comma less than the octave.

SEVEN YEARS' WAR. In History, a war carried on in Germany between two alliances, headed respectively by Austria and Prussia, from the year 1756 to 1763, when it was ended by the peace of Hubertsburg. It was signalized chiefly by the extraordinary campaigns of Frederick II., the Great King of Prussia. His principal ally throughout the struggle was England; while he was, at one period, assailed by the forces of Austria, France, the Empire, Sweden, and Russia. When the forces of the Prussian sovereign had been almost annihilated by this coalition, the death of the Russian empress, Elizabeth, caused the withdrawal of Russia from the alliance of his enemies, and thus brought about the termination of the war without material advantages gained by any party.

SEWER. In Architecture, a subterraneous conduit, or channel, to receive and carry off the superfluous water and filth of a city. The sewers of Rome have been the models of those of the modern cities of Europe. They are as old as the elder Tarquin. These *cloacæ* had, between the Quirinal, Capitoline, and Palatine hills, many branches, which joining in the Forum, now the Campo Vaccino, were received for conveyance into the Tiber by a larger one, called the *cloaca maxima*. It must be admitted, however, that it is erroneous to designate the Roman cloacæ by the term sewers. They were rather drains, made to carry off the stagnant water of the pestilential marshes which occupied much of the low ground near the Tiber, and the spaces between the Aventine, Palatine, and Capitoline hills. The height and width of the cloaca maxima are equal, each measuring 13½ feet.

SEXAGE'SIMA. (Lat. *sixtieth*.) In the Calendar, the eighth Sunday (nearly sixty days) before Easter.

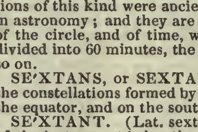
SEXAGE'SIMAL ARITHMETIC. A method of computation proceeding by sixties (as the common arithmetic proceeds by tens), and used by the ancient Greek astronomers for facilitating arithmetical calculations, particularly division and the extraction of roots; operations which, when performed on numbers expressed by the complicated Greek notation are attended with great labour and difficulty.

SEXAGE'SIMAL FRACTIONS, are such as have 60, or some multiple of 60, for their denominator. Fractions of this kind were anciently the only fractions used in astronomy; and they are still retained in the division of the circle, and of time, where the degree, or hour, is divided into 60 minutes, the minute into 60 seconds, and so on.

SE'XTANS, or SEXTANT. In Astronomy, one of the constellations formed by Hevelius. It is placed across the equator, and on the south side of the ecliptic.

SE'XTANT. (Lat. sextans, *the sixth part*; the limb of the instrument being the sixth part of a complete circle.) An instrument for measuring the angular distances of objects by reflexion. The sextant is capable of very general application; but it is chiefly used as a nautical instrument for measuring the altitudes of celestial objects, and their apparent angular distances. It is an instrument of the utmost importance in navigation.

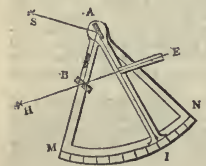
The principle of the sextant, and of reflecting instruments generally, depends upon an elementary theorem of catoptrics; viz. if an object be seen by reflexion from two mirrors which are perpendicular to the same plane, the angular distance of the object from its image is double the inclination of the mirrors. Thus, let A and B be sections of two mirrors perpendicular to the same plane, and inclined to each other in the angle A I B; a ray of light coming from the sun and falling upon the mirror A, in the direction S A, will be reflected in the line A B; and falling upon B, it will again be reflected in the direction B E. Let A B be produced to D, and S A prolonged to meet B E in E. Now, since the angles of incidence and reflexion are always equal (*see* Reflexion), we have D B E = 2 D B I, and B A E = 2 B A I; but D B E = B A E + B E A, and D B I = B A I + B I A, consequently B A E + B E A = 2 B A I + 2 B I A; and therefore, since B A E = 2 B A I, we have also B E A = 2 B I A; that is to say, the angular distance between the object S and its image seen by the eye at E, in the direction E B H, is the double of the in-



clination of the mirrors. It may be remarked, that the place of the image, as seen from E, is independent of the situation of the mirrors on the plane, so long as the line of the intersection of their planes and their inclination to each other remain constant.

From what has been now said, it may be seen that if a convenient method could be devised for measuring the inclination of two mirrors perpendicular to the same plane, when they are so placed that the image of an object S is brought to coincide with an object H seen directly, we should at once have a reflecting instrument for measuring angular distances. Such instruments are the *sextant*, the *quadrant*, the *reflecting circle*, respectively so called from the extent of the arc which the graduated limb embraces.

The contrivance adopted for this purpose in the sextant is to attach the frame of the mirror B to the plane of the sector of a circle A M N, and the frame of the mirror A to a radial bar A I revolving in the plane of the sector round a pin passing through the centre. Both frames are generally supplied with the means of adjusting the planes of the mirror vertically, and B is generally also capable of being turned by a delicate motion a small way round a pin passing through the frame of the sector.



The arc or *limb* M N of the sector is graduated; and the revolving radius or *index* carries at its extremity a vernier scale, applying to the graduations on the limb, and subdividing them into such smaller portions as may be desired.

The method of finding the zero point of the limb may be understood generally from the following considerations: — The angle E (see the first figure) being double the angle I, it follows that when the mirrors are parallel, or the angle I is nothing, the angle E is nothing also, and S and its image will appear as one object, the one exactly covering the other. It is therefore only necessary to turn round the radial bar which carries A till the image of a distant object seen by reflexion from B is in accurate conjunction with the object itself, seen directly; and the point on the limb at which the index then stands is the zero point of the arc. If it is not also the zero of the numbered graduations, its distance from the numeral zero is called the *index* error of the instrument, and is to be applied as a correction to all angles measured.

In graduating the limb, half degrees are marked as whole ones, and the smaller divisions accordingly; so that the angle read from the instrument is not the inclination of the mirrors, but the distance of the object from its image. In this class of instruments, therefore, 90° are indicated by an arc of 45°, 120° by an arc of 60°, &c.

The mirror A is completely silvered behind; but B is silvered on that half only which is next the plane of the instrument, the upper part being left clear, that objects, such as H, may be seen *through* it, as well as the images of others, as S, by reflexion *from its surface*. The mirror B is so placed by the maker that when A is parallel to it, the index which carries A either exactly or nearly corresponds with the zero of the divisions as they are numbered on the limb. When the index has been set by hand nearly in the position requisite for measuring any proposed angle, it is clamped to the limb by a screw acting on a spring, and moved slowly by a tangent screw till it attains accurately the required position.

Such being the general principles of the instrument, we shall now briefly describe the different parts of it, as constructed by the best makers, and the methods of adjusting and observing with it.

The only important object to be aimed at in the frame is to combine lightness with sufficient strength. The frames are generally of brass, and cast in one piece from a model; but the late Mr. Troughton introduced thin double frames parallel to each other, and connected by pillars. These frames are very light; but it may be doubtful whether they sufficiently fulfil the condition of strength.

In all good instruments the index is strengthened by an *edge bar* along its length. The graduations are made on a slip of gold, silver, or platina, which is *let in* to a groove in the limb. Instruments of this kind are now all graduated by a dividing machine.

The frame of the sextant is supported by three feet, one near each end of the limb, and the third at the centre, where it serves also as a sheath to cover the central pin (with its fastening screw) round which the index revolves. A handle parallel to the frame is attached to the back of it, to hold the instrument by when observing.

The revolving mirror A is attached by three screws to the head of the index. In common instruments only two of these screws are fastening screws, and the third is used as an *adjusting* screw for placing the mirror perpendicular to the plane of the instrument. But in the better class of instruments all three are *fastening* screws, the maker himself placing the mirror in its perpendicular position.

The other mirror, B, is attached to the frame of the sector, and in some instruments is incapable of lateral motion, being only provided with the means of placing it perpendicular to the plane of the instrument; so that the position of its plane with respect to the graduations may be regarded as permanent. The vertical adjustment is effected by a screw, which sometimes acts on the frame; and in some instruments directly on the mirror, on which it presses by means of a spring. In other instruments the frame of this mirror turns round an axis passing through the frame of the instrument; so that when the index is set to zero on the limb, B can be set parallel to A, and the index error, therefore, reduced to nothing. This mirror B is called the *horizon glass* by seamen, and the adjustment we have been speaking of is called the *parallel adjustment* of the horizon glass. It is a most important adjustment, and one that requires continual attention, being liable to be altered by very trifling causes.

In common quadrants, a sight vane with two holes is placed (as at E) opposite B, one hole at the same distance from the plane as the upper edge of the silvered part of the mirror, and the other opposite the middle of the unsilvered part. But the best instruments, instead of the sight vane, are furnished with telescopes, which screw into a socket attached to a piece of brass passing through the frame of the instrument; and by means of a screw the socket can be raised or depressed, so that the telescope can be placed with more or less of the object-glass opposite the silvered or the unsilvered part of the index glass, as the varying brightness of the objects observed may render necessary.

The telescopes are of two kinds. One, a direct telescope, which is simply an opera-glass; and having a narrow field of view, is generally used in the more ordinary sort of observations, such as observing altitudes. The other is an inverting or astronomical telescope, which has a large field of view, and is that which dexterous observers use exclusively. It is commonly supplied with two eye-pieces; one of considerable power, and chiefly for determining the index error, and the other for observing with. In the frames of each eye-piece are two pairs of wires, each pair perpendicular to the other, dividing the field of view into nine spaces, of which that in the middle is square; and it is important that in all observations made with this instrument the contact of the image seen by reflexion, and of the object seen directly, should be made as near the middle of this square as possible, at any rate at the same distance as the centre of the square from the plane of the instrument.

It is essential, also, that the telescope should be parallel to the plane of the instrument; and in the collar into which the telescope is screwed there are two screws for making this parallel adjustment. The adjustment is not very liable to alter, but no careful observer will omit to examine it at every convenient opportunity.

Both the mirrors are supplied with coloured glasses of different degrees of shade, framed and placed in such a position that they can be turned down before the mirrors, either singly or combined. The eye-pieces of the telescopes are also supplied with coloured shades, set in caps, which are screwed on the eye-piece. They are used in taking the index error by means of the sun, and in observing the sun's altitude from an artificial horizon.

Adjustment of the Sextant. — 1. To set the index glass, when it admits of adjustment, perpendicular to the plane of the instrument.

Place the index about the middle of the limb; and looking obliquely into the index glass, the part of the limb will be seen by reflexion in the glass, as well as directly. If the part of the limb seen directly and its image in the glass appear as one continued frame, the mirror is in adjustment; but if the reflected image appears to incline downward, it shows that the face of the glass inclines backward from the perpendicular; if upwards, that it inclines forward, and the adjustment must be made by the screw supplied for the purpose.

2. To set the horizon glass perpendicular to the frame of the instrument.

Having carefully adjusted the index glass, or seen that it is in adjustment, screw the telescope into its socket; adjust the eye-piece to distinct vision; screw the dusk shade cap on the eye end of the telescope, or turn down shades before the mirrors; and looking towards the sun, bring the index near to zero; move it steadily backwards and forwards, and the reflected image of the sun will be seen to pass over his disk, as viewed directly. If the two circular disks accurately cover each other in passing, the perpendicular adjustment of the horizon glass requires no adjustment; but if they pass a little aside of each other, so that two different-coloured lines appear on each side of the overlapping middle part, the mirror B must be turned by the appropriate screw

till the disks accurately cover each other, when the adjustment will be complete. This adjustment may also be effected by making a bright star and its image coincide with each other; but in this case it is scarcely necessary to say that the darkening shades must be turned aside.

3. To set the telescope parallel to the plane of the instrument. This adjustment is effected by two screws in the collar which attaches the telescope to the limb of the sextant, and diametrically oppose each other in a line perpendicular to the plane of the instrument. By tightening the upper one the object end of the telescope is inclined towards the instrument, and the contrary effect is produced by tightening the lower one. To make the adjustment, turn round the eye-piece of the telescope till two of the wires in its focus appear parallel to the plane of the instrument (and of this the eye can judge with sufficient accuracy); then take two objects, as two bright stars, or the sun and the moon, whose distance in either case should not be less than 90°, in order that any error in the adjustment may become more apparent, and bringing the image of one of the objects in accurate contact with the other object on the wire next the instrument, *instantly* bring them to the other wire; and if they are also in accurate contact upon that wire, it may be concluded that the axis of the telescope is parallel to the plane of the instrument. If the objects are the sun and moon, and they separate at the farther wire, it shows that the object end of the telescope inclines towards the plane of the instrument, and the contrary if they overlap, and the error must be corrected by turning the proper screws in the collar.

The above are all the adjustments which this class of instruments admits of, and they are essential to every instrument of the kind. We have now only to state how, in practice, the index error of the instrument may be most conveniently and accurately determined.

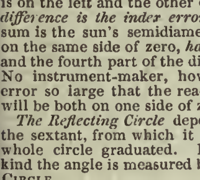
Having effected the perpendicular adjustment of the horizon glass by the method above explained, bring the border of the sun's reflected image to coincide with the sun seen directly both on the right and left side; and, reading the index at both observations, if one reading is on the left and the other on the right of zero, *half the difference is the index error*, and the fourth part of the sum is the sun's semidiameter; but if both readings are on the same side of zero, *half the sum is the index error*, and the fourth part of the difference is the semidiameter. No instrument-maker, however, will leave the index error so large that the readings for the sun's diameter will be both on one side of zero.

The Reflecting Circle depends on the same principles as the sextant, from which it differs chiefly by having the whole circle graduated. In some instruments of this kind the angle is measured by repetition. *See* REPEATING CIRCLE.

But the only instrument of this kind that can be now said to be in general use in this country is Troughton's reflecting circle; in which, by means of three equidistant indexes, and by observing alternately with the face of the index direct and reversed, *six times* the required angle is obtained, without reference to the index correction. After what has been said above on the principles of reflecting instruments generally, the following short account of this instrument will be sufficient.

All the indexes move round together; and, of course, the apparatus for slow motion, or the tangent screw, is only requisite for one of them, which is called the *leading* index, and which, for the sake of convenience, stands at or near zero on the limb when the revolving and fixed mirrors are parallel.

In the annexed figure let B D, B E, and B F, be the positions of the indexes when the revolving mirror is parallel to the fixed one K L; and let A C and M N be two positions of the revolving mirror when it is equally inclined to K L. Then the arcs D G, D G′, E H, E H′, F I, F I′, passed over by B D, B E, and B F, will be all equal; and if, when the mirror has the position M N, the face of the instrument be reversed, M N and K L will have the same relative position to each other that A C and K L have; and consequently if an object is seen by reflexion from A C and K L, it will also, when the instrument is reversed, be seen by reflexion from M N and K L to an eye placed in the same situation. Hence the degrees on the arcs G G′, H H′, I I′, which are the differences of the readings of the observations in the direct and reversed positions, are each the measure of double the distance of the object from its reflected image. The degrees being numbered round the circle from 0 to 720°, and the indexes placed very nearly at equal distances from each other, it is customary in practice to read the degrees, with the minutes and seconds, from the leading index only, and to read only the minutes and seconds at the other indexes.



SE′XTILE ASPECT, in Astrology, is the aspect of two planets when they are distant from each other the sixth part of a circle, or sixty degrees.

SE′XTON. (Lat. sacristanus, sacrista.) A church officer, who is properly the keeper of holy things belonging to divine worship, and said to be the same with the *ostiarius* in the Romish church. A sexton is usually appointed for life (whether by the minister or others, according to custom), and in such case a mandamus lies to restore him to his office.

SFORZA′TO. (It. *forced.*) In Music, a term written over a note to signify that it is to be played or struck louder than the rest.

SFUMA′TO. (It. *smoky.*) In Painting, a term applied to that style of painting wherein the tints are so blended that the outline is scarcely perceptible, the whole presenting an indistinct misty appearance. Guercino's works present some of the finest examples of the style.

SGRAFI′TTO. (It. *scratched.*) In Painting, a species of painting in which the ground is prepared with dark stucco, on which a white coat is applied; which last being removed with an iron instrument, the chipping it away opens to the black ground and forms the shadows, giving it the appearance of a chiaro-scuro painting. The principal pictures of Polidoro da Caravaggio are executed in this manner, which is capable of great effect, and is extremely durable, though it must be conceded the appearance is rather harsh.

SHABRACK. The cloth furniture of a cavalry officer's charger. The term is of Hungarian origin.

SHA′DDOCK. The fruit of the *Citrus decumaria:* it is a species of orange.

SHA′DOW. In Optics, a portion of space from which light is intercepted by an opaque body. As the rays of light proceed in straight lines, every opaque object on which light falls is accompanied with a shadow on the side opposite to the luminous body; and the shadow appears more intense in proportion as the illumination is stronger, because any object placed within it contrasts more strongly with the surrounding objects on which the light is suffered to fall.

As every point of a luminous body is a separate focus of illumination, it follows that an opaque object illuminated by the sun, or any other source of light which is not a single point, must have an infinite number of shadows, though not distinguishable from each other; and hence the shadow of an opaque body received on a plane is always terminated by a *penumbra*, or partial shadow, the extent of which is greater in proportion to the magnitude of the luminous body, the distance of the opaque body from the plane on which the shadow falls, and the degree of obliquity with which the luminous rays fall on the plane.

Shadows are said to be *right*, or *versed*, according to the position of the planes on which they are thrown. The shadow of an upright body projected on the plane of the horizon is a right shadow; and that of a body on a vertical plane to which the body is perpendicular, as that of a bar of iron fixed perpendicular in a wall, is a versed shadow. In both cases, the length of the shadow is to the height of the opaque body as the cosine to the sine of the angle which the luminous ray makes with the plane. The ancient geometers availed themselves of this property of shadows to measure the altitudes of objects.

Coloured Shadows.— In certain states of the atmosphere the shadows of opaque objects projected on a white surface are frequently observed, about the time of sunrise or sunset, to be of a blue colour. This curious observation appears to have been first made by the celebrated painter Leonardo da Vinci, and is also noticed by Otto Guericke in his *Magdeburg Experiments;* but no further notice seems to have been taken of the phenomenon until about a century later, when it again occurred to Buffon. Happening to be standing on an eminence about the time of sunset, he perceived the shadows of the trees on a white wall about 30 or 40 feet distant to be coloured with a light green, inclining to blue. The next morning, at sunrise, he repeated the observation; but instead of finding the shadows green, he found them blue, or rather the colour of lively indigo. Afterwards he often observed the shadows both in the morning and evening, but always observed them to be blue; and he remarks that any one may see a blue shadow, if he will hold his finger before a piece of white paper at sunrise or sunset. The phenomenon has since been frequently observed; and it is usually ascribed to the aërial colour of the atmosphere, which enlightens the shadows, and in which the blue rays prevail. (See *Priestly's History of Light, &c.*, 1762.) For remarks on shadows with luminous borders, *glorified shadows*, and other optical phenomena of the same kind, see Prof. Forbes's Report on Meteorology in the *Reports of the British Association for* 1840.

SHADOW. In Painting, the form which a solid object projects on a surface or surfaces by being interposed

between the surface or surfaces and the sun, or other luminous body; the doctrines whereof have received the name of *sciography*. *Shade* is a term applied to that portion of the object which is not obvious to the luminous body.

SHAFT. In Architecture, that part of a column between the base and capital, sometimes called the *trunk* of the column. The shaft of a column always diminishes in diameter from about a third of its height. Sometimes it has a slight swelling (*see* ENTASIS) in the lower part of its height. In the oldest Doric columns, the diminution was so considerable as to give the column a conical appearance. In the Doric edifices at Athens, the upper diameter is not more than a quarter less than the lower diameter; in the temples of Jupiter Nemeus, between Argos and Corinth, not more than a fifth less. In Ionic and Corinthian columns, the difference of the upper and lower diameters varies from a fifth to a twelfth. The ancients seem to have regulated the diminution in some proportion to the absolute height of the column, for no particular law seems to have prevailed in terms of the lower diameter.

SHAFT. In Mines. A shaft or pit is a prismatic or cylindrical hollow space, the axis of which is either vertical or much inclined to the horizon. The dimension of the pit, which is never less than 32 inches in its narrowest diameter, amounts sometimes to several yards. Its depth may extend to 1000 feet, and more. Whenever a shaft is opened, means must be provided to extract the rubbish which continually tends to accumulate at its bottom, as well as the waters which may percolate down into it; as also to facilitate the descent and ascent of the workmen. For some time a wheel and axle erected over the mouth of the opening, which serve to elevate one or two buckets of proper dimensions, may be sufficient for most of these purposes; but such a machine becomes ere long inadequate. Horse-whims, or powerful steam-engines, must then be had recourse to; and effectual methods of support must be employed to prevent the sides of the shaft from crumbling and falling down. (*Ure's Dict. of Arts, &c.*)

SHAG. The English name of a species of cormorant (*Pelicanus graculus*, Linn.).

SHAGREE'N. A species of leather, supposed formerly to have been prepared from the skin of the *shagree*, a species of whale. It is prepared from horse or ass skin, its granular appearance being given by embedding in it, whilst soft, the seeds of a species of chenopodium, and afterwards shaving down the surface: it is dyed with the green produced by the action of sal ammoniac on copper filings. It was formerly much used for watch, spectacle, and instrument cases, and was made chiefly in Astracan.

SHAH. (In Persian, *prince*.) The title given by European writers to the monarch of Persia, who in his own country is designated by the compound appellation of *Padishah*, which see.

SHAH-NAMAH. (*The Book of Kings.*) The most ancient and celebrated poem in the modern Persian language, by the poet who received as a title of honour the name "Firdousi" (*of Paradise*), by which he is known. Its date is supposed to be about A. D. 1000. A complete translation into English, in four volumes, was published by Capt. Macan, Calcutta, 1829.

SHAKE. In Music, a quick alternate repetition of the note above with that over which the mark *tr* is placed, commonly ending with a turn from the note below.

SHAKERS. In Ecclesiastical History, a sect said to have originated by a secession from the body of Quakers, in 1747, in Lancashire; who received their nickname from the peculiar contortions of body which they adopted in their religious exercises. Anne Lee, the great female leader of this sect, joined the society in 1758; and considering herself persecuted in England, went, with a few followers, to New York in 1774, and died ten years afterwards, at which time her sect had made great progress in America. She was considered as the woman spoken of in Revelations. The sect appears to have fallen into obscurity, although a few congregations still remain.

SHALE. A crumbling variety of slate.

SHA'MANISM, or SCHAMANISM. A general name applied to the idolatrous religions of a number of barbarous tribes, comprehending those of Finnish race,—the Ostiaks, Samojeds, and other inhabitants of Siberia as far as the Pacific ocean. These nations generally believe in a Supreme Being, but to whom they attribute little share in the immediate government of the world: this is in the hands of a number of secondary gods, both benevolent and malevolent towards man. They appear to have very uncertain and fluctuating opinions respecting these last. Thus, those tribes which dwell on the frontier of Russia are said to admit Saint Nicholas among their gods. The *shamans* or priests possess the power of propitiating such as are malignant. These priests are called by various names in different tribes. The general belief respecting another life appears to be, that the condition of man will be poorer and more wretched than in the present; hence death is an object of great dread. Women are esteemed very inferior to men by all these nations. The magic drum of the priests is well known. For one of the latest accounts of these remote people, see *Von Wrangel's Journey to the Polar Sea.*

SHAMMY, or SHAMOY. The tanned or tawed skin of the Chamois goat. Any soft pliable leather now passes under the name. *See* LEATHER.

SHAMPOOING. A name given to an operation in the East, which consists in pressing the joints and rubbing them, so as to mitigate pain, and restore tone and vigour to the parts.

SHAMROCK. The popular emblem of Ireland: as the rose of England, and the thistle of Scotland. It is generally supposed to have been the plant called white clover, *Trifolium repens*; but it appears to have been rather the wood sorrel, *Oxalis acetosilla*.

SHANK. In Architecture. *See* FEMUR.

SHANK PAINTER. The rope or chain which passing round the shank of the anchor, lying horizontally, confines it to the ship's bow.

SHARP. In Music, a character ♯, which prefixed to a note signifies that it is to be sung or played a semitone higher than it naturally would have been without such character.

SHEAF. In Mechanics, a solid cylindrical wheel fixed in a channel and moveable about an axis, as in the block of a pulley.

SHEA'RING. The term in Scotland for reaping.

SHEARING SHEEP. The operation of clipping off the wool from the bodies of ewes and lambs; generally performed in the beginning of summer, when the animals are not likely to suffer from being deprived of their warm covering, and when there is sufficient time for the wool to grow again before winter.

SHEATH, in Botany, is a term applied to a petiole when it embraces the branch from which it springs, as in grasses; or to a rudimentary leaf which wraps round the stem on which it grows, as in the scapus of many Endogenous plants.

SHEATHING. The covering laid on the ship's bottom to defend it from the worms. Sheets of thin copper nailed on with copper nails constitutes, at present, the sheathing of all the better kinds of vessels. Lead has been used; and large-headed iron nails, called scupper nails, are used still for the same purpose on the bottoms of old hulks, piles, &c. Zinc and different compositions have been proposed as substitutes for copper; and Sir H. Davy ingeniously suggested the application of pieces of zinc or iron upon different parts of the copper surface, which by the action of the sea water render the latter metal electro-negative, and capable, therefore, of resisting the oxidizing and corrosive agencies of the substances held in solution. The pieces of iron or of zinc so applied have been properly called *protectors;* but by occasioning the precipitation of earthy matters upon the copper, while they effectually *protect it* they render its surface favourable to the adhesion of weeds, barnacles, &c., and sometimes to such an extent as to interfere with the passage of the ship through the water: upon such grounds Sir Humphrey's valuable suggestion has been neglected. When vessels are laid up in dock the protectors are in successful use. Sheathing formerly was composed of thin fir boards.

SHEEP. *See* OVIS.

SHEER. The curve which the line of ports, or of the deck, presents to the eye when viewing the side of the ship. When these lines are straight, or the extremities do not rise, as is most usual, the ship is said to have a straight *sheer*.

SHEER HULK. A hulk permanently fitted with sheers for masting and dismasting ships.

SHEERS. Two masts or spars lashed together at or near the head, and raised to a vertical position, for the purpose of lifting the masts into or out of a vessel.

SHEET. The rope attached to the after mast or leeward mast clue or corner of a sail, to extend it to the wind. In the square sails above the courses, the ropes attached to both clues are called *sheets:* in all other cases the weathermost one is called a *tack*.

SHEET ANCHOR. The third of the four large anchors generally carried by a ship.

SHEIK. (In Arabic, *elder or eldest.*) A title of dignity properly belonging to the chiefs of the Arabian tribes or clans. The heads of monasteries are also termed, in some instances, sheiks among the Mohammedans. It is also the title of the higher order of religious persons who preach in the mosques. The mufti of Constantinople bears the title of Sheikh-ul-Islam.

SHEKEL. The name of a weight and coin in use among the Jews. The weight of the shekel was about ½ oz. in English avoirdupois weight; and the value of the coin was 2*s.* 7*d.* There were two standards of the shekel: the shekel of the *sanctuary*, which was used in calculating the offerings of the temple, and all sums connected with the sacred law; and the *royal* or *profane* shekel, used for all civil payments. Various opinions are entertained respecting the relative value of these two stan-

dards; but nothing certain can be averred on the subject. Wener and Michaelis, without, however, any sufficient reason, as it appears, are of opinion that the shekel used in commercial transactions differed from both of these. (See Wener, *Biblisches Realwörterbuch*, art. "Sekel.")

SHEKI'NAH. The Jewish name for the Divine presence, which rested, in the shape of a cloud, over the "propitiatory," or "mercy seat," as it is rendered in our translation (Leviticus, xvi. 2.). The Jews reckon it among the five particulars which were present in the first temple, and wanting in the second. (See *Prideaux' Connection*, l. 3.) On this account God is so often said in Scripture to "dwell between the cherubim;" that is, between the images of cherubim on the mercy seat. (1 Sam. iv. 4.; Psalm lxxx. 1. &c. See also *Mem. de l'Ac. des Inscr.* vol. xxxviii.)

SHE'LDRAKE. The common name of the species of duck called *Anas tadorna*, which is the type of the subgenus *Tadorna* of Ray and modern ornithologists. This elegant species frequents many parts of our coast, and remains throughout the year. The female commonly selects a rabbit-hole in which to deposit her eggs, which are sometimes as many as sixteen in number. The sheldrake feeds on small fish, marine insects, and sea-weed.

SHELL. The hardening principle of shell is generally carbonate of lime nearly pure. The animal principle, in the porcellaneous shells, is a small quantity of soluble gelatine; in the mother of pearl shells, it is albuminous. The latter, therefore, when steeped in dilute muriatic acid, leave a membranous or cartilaginous residue; but the former are entirely soluble. For the form, structure, and mode of growth of shell, see CONCHOLOGY.

SHELL. In Artillery, a hollow sphere of iron, which, being filled with gunpowder and fired from a mortar, bursts into pieces; when the powder is exploded, and produces a very destructive effect. The charge is introduced through a hole in the shell of about an inch in diameter, and fired by means of a fuze. The fuze is a wooden tube made to fit the hole, and filled with a composition of sulphur, saltpetre, and mealed powder; and is cut of such a length that the shell is calculated to explode just before or immediately after it reaches the ground.

SHELL MARL. A deposit of clay and other substances, mixed with shells, which collects at the bottom of lakes.

SHE'RBET (a word borrowed from the Persian), signifies a favourite beverage in the East, bearing some resemblance to our lemonade, made of water, lemon-juice, and sugar, with the addition of some other ingredients, such as rose water, to give it a delightful perfume.

SHE'RIFF (originally shire-reeve, from the Saxon, meaning the reeve or governor of the shire), is the title of that functionary who acted at first only as the deputy of the earl, hence styled in Lat. *vice-comes*; but has long been the chief civil officer in each county, where he is styled bailiff of the crown, and where he is specially entrusted with the execution of the laws and the preservation of the peace: for which purposes he has at his disposal the whole civil force of the county, — in old legal language the *posse comitatus*. The most ordinary and important functions of the sheriff, which he universally exercises by a deputy, called under-sheriff, for whose conduct he is responsible, consist, 1st, In the execution of writs issuing from the superior courts, or awarded by the judges on their consent, to take effect within the county. 2. In the holding of the sheriff's court. The sheriff himself only executes in person such parts of his office as are either purely honorary, such as attendance upon the judges on circuit (for whose lodging he is also bound to provide); or as are of some dignity and public importance, such as the presiding over elections and the holding of county meetings, which it is in his power to call at any time. The county courts are incident to the jurisdiction of the sheriff. Until recently they could only hold pleas of debt or damages under the value of 40*s*., except in replevin, or actions by virtue of a particular writ termed a *justicies*. But it is now enacted, by 3 & 4 W. 4. c. 42., that in any action depending in a superior court for a debt or demand, not exceeding 20*l*., it shall be lawful for the court to direct that the issue joined shall be tried before the sheriff of the county in which the action is brought. *See* COURTS.

Sheriffs were originally chosen by the freeholders of the county, except in some few counties where the office was hereditary, as it still is in Westmoreland. The system of popular election was abolished in the reign of Richard II., and sheriffs have long been appointed by the crown upon presentation of the judges, in a manner partly regulated by law, partly by custom; but sheriffs may also be nominated by the crown without recommendation of the judges, and are then familiarly styled *pocket sheriffs*. Those appointed in either way are bound under a penalty of 500*l*. to serve the office, except in specified cases of exemption or disability. The description given of the office as it is in England applies to Ireland without variation, except as to the time of its origin.

SHE'RIFF DEPUTE. In Scotland, the principal sheriff of a county. He is named by the crown, must be an advocate of three years' standing, and receives a salary varying from 350*l*. to 1200*l*. per annum. He is entitled to name sheriff substitutes; executes writs, returns juries, &c.; decides on claims for enrolment in the county lists of parliamentary voters, and exercises a certain criminal jurisdiction. He holds also civil courts for the recovery of small debts, and a court of record, the jurisdiction of which extends to all personal actions, and possessory actions for the recovery of real property.

SHE'RRY. A Spanish wine made from the grapes of Xeres in Andalusia. Genuine sherry is a rich dry wine, containing from 20 to 23 per cent. of alcohol: there are many varieties, and it is extensively imitated and adulterated. *See* WINE.

SHEW-BREAD. In the Old Testament. The name given to the twelve loaves of bread, one for each of the twelve tribes of Israel, which were appointed to be placed every Sabbath "on the pure table before the Lord," for the sustenance of the priests. They appear to be the same with that which is called "shew-bread" in 1 Sam. 21., where the act of David in taking these loaves for the nourishment of himself and his followers is related.

SHI'BBOLETH. (Heb. *a flood*.) The name given to a sort of test or criterion by which the ancient Jews sought to distinguish true persons or things from false. The term originated thus: — After the battle gained by Jephtha over the Ephraimites (see Judges, xii.), the Gileadites commanded by the former secured all the passes of the river; and on an Ephraimite attempting to cross, they asked him if he was of Ephraim. If he said no, they bade him pronounce the word *Shibboleth*, which the Ephraimites from inability to give the aspirate called *Sibboleth*; and by this means he was detected and instantly thrown into the river. In modern times this word has been adopted into the language of politics, in which it signifies those political opinions on which all the members of a party are agreed, or the watch-word by which it is intended to unite them.

SHIELD. (Germ. schild.) A well-known piece of defensive armour, very extensively used before the invention of gunpowder, and still employed by many nations among which military art has made imperfect progress. It would be endless to detail the various materials and shapes of which it has been constructed at different periods. The ancient Greek shield, as described in Homer, was large and massive, sufficient to cover the man from the face to the knee, composed of leather, inlaid in some instances with metal. That of the Roman legionary was four feet high, and two and a half broad, formed of wood covered with leather, and strongly guarded with bosses of iron or bronze. The ancient Britons and other nations of antiquity wore round, light, basket-like shields, often of wicker-work; more resembling the parma or lighter shield of the Romans. The Norman shield, as used in England down to the time of Henry II., was "of the form called kite or pear-shape," flatter at first, afterwards approaching to the semi-cylindrical. Heraldic devices were first borne on it, so far as is distinctly ascertained, in the reign of Henry II. (*Pictorial Hist. of England*, i. 640.) In that of Edward IV. the shield had become triangular: the point of the triangle was rounded off about the end of the 14th century. Afterwards the shape of the shield, as worn by knights, became more and more fantastic. In actual service it fell gradually into disuse: sword and buckler fight, the favourite pastime as well as warlike practice of former days, became obsolete after the rapier and dagger had been introduced in the reign of Elizabeth. The Highlanders carried the target with the broad sword to a much later period.

SHIELDS. In Botany, little coloured cups or lines with a hard disk, surrounded by a rim, and containing the fructification of lichens.

SHILLING. An English silver coin equal to twelve pence, or the twentieth part of a pound sterling. Among the ancient Saxons, the value of the shilling was only five pence; it afterwards underwent many alterations, containing sometimes sixteen pence, and often twenty pence. The period when it obtained its present value is assigned to the reign of Edward I. Many other countries besides England have a coin of this name; of these, perhaps, the Hamburgh schilling is the best known. Its value is 1*d*. English.

SHI'LOH. (Hebr. differently rendered — *Son*, *He who is sent*, or *the Sent*, or *the Peaceable*, or *the Prosperous*.) The name given to the Messiah by Jacob in his prophecy, Genesis, xlix. 10.

SHINGLE. (Germ.; or perhaps from Lat. scindendo.) The coarse gravel, or accumulation of small stones, found on the shores of rivers or the sea: in the latter case the term *sea-beach* is applied.

SHI'NGLES. A corruption of the French word *ceingle*, which means *a belt*. This eruptive disorder is generally ushered in with febrile symptoms, followed by an itching or tingling sensation of some part of the body, occasioned by patches of little red pimples, forming in the course of twenty-four hours small transparent ve-

sicles; these succeed each other till they at length form a kind of belt round some part of the trunk or abdomen; they often form small ulcerations and scabs, continuing their progress for three or four weeks. This disorder is not contagious, and generally very slight; but in irritable habits the itching occasions want of rest and fever, and it is sometimes attended by a deep-seated pain of the affected part. The cause of shingles is generally obscure, though it may sometimes be referred to indigestion and suppressed perspiration: young persons are most subject to it. Gentle aperients and diaphoretics, strict attention to the diet, and occasional anodynes, are the only internal remedies generally required; and, externally, a little cold cream or fresh spermaceti ointment, or the occasional application of a very weak Goulard's lotion, is all that is necessary.

Shingles. In Architecture, small slabs of wood, or quartered oaken boards, used instead of slates or tiles for covering churches or spires. They are sawn to a certain scantling, or rather cleft to about an inch thick at one end, and shaped like wedges, four or five inches broad and eight or nine inches long.

SHIP. A general term for all large vessels, but restricted by seamen to such only as have three complete masts; *i. e.* lower, top, and top-gallant masts. As we cannot here give a complete description of so complex a fabric, and as the reader will have become familiar with the forms of ships from prints, we shall merely attempt to convey some general ideas on the subject. After the hull has been completed, a slight account of the construction of which has been given under Naval Architecture, the ballast, which is necessary in most ships to keep them upright when under sail, and which is in men-of-war in iron pigs, is spread over the bottom of the hold, chiefly towards the middle of the length. The masts are then taken in. On the ballast are laid loose pieces of wood, called *dunnage*, on which rest the iron tanks containing the water to drink, or water casks. The hold in large ships is divided by partitions into the fore, main, and after holds. At the fore extremity, in men-of-war, are the gunner's, boatswain's, and carpenter's store rooms, containing arms, supplies of rope, bolts, pump gear, and other materials of the fittings, or for repairs. In this part also is the fore powder magazine, when there are two. In the fore hold are stowed water, wood for firing, and, separated by a strong partition, coals. In the main hold are stowed water, stores, chain cables, &c. In the after hold are the provisions; and, in the *spirit room*, the spirits: here also is the powder magazine. In the narrow and shallow after extremity is stowed the bread or biscuit. The spare sails are kept in a space called the *sail room*, over the fore hold. The hemp cables are kept in the cable tiers, on a deck over the main hold. These decks immediately over the holds constitute generally the fore and after *cock pits*. In large ships the whole deck is called the *orlop* deck. On the *lower* deck, which is next above the former, the men mess and sleep. In frigates, and smaller vessels, this deck is a little below the water; in two and three deckers, it is three or more feet above the water, and is the lower gun deck.

In merchant ships the arrangements depend, of course, on the size of the vessel and the nature of the cargo. In all these vessels, however, the place allotted to the crew is in the fore part, and is called the *fore peak*. Ships are, in general, constructed for the purposes of burden, expedition, and war; the latter class, which must possess also, in part, the qualities of the other two, exhibit the finest models. The largest ships, of 120 guns, carry three complete rows or tiers of heavy cannon (32-pounders), and are thence called three-deckers; of late years some still heavier guns have been introduced. Each deck has from 15 to 17 guns on each side. The middle of these decks is called the *middle* deck; and the deck next above this, or which is next below the uppermost deck, the *main* deck. Guns are also carried on the upper deck, of which the fore part is called the *forecastle*, and the part abaft the main mast the *quarter* deck. The deck over this last, extending from the after extremity to a little before the mizzen mast, is called the *poop*. The after parts of these decks, from and including the mizzen mast, are the cabins of the admiral, captain, and the officers; the latter being called the *ward room* in ships of the line, and the *gun room* in frigates. The length of a ship of the largest class is about 200 feet at the water line, extreme breadth 54 feet, and draught of water about 26, and the height of the truck above the water 210 feet. The whole weight of such a ship, with her crew and provisions, is about 4600 tons, of which the hull or shell is about half. The men, with their effects, amount to 100 tons; and the guns, arms, and powder, to 500 tons. The 32-pounder (long gun), and carriage, weigh 72 cwt., and the carronade one third of this. Two-deckers carry from 70 to 90 guns. In bad weather the ports of the lower deck are defended by heavy lids called *ports*, which are firmly secured from within, the guns being then run in and secured from motion. Frigates carry one tier of guns on the main deck, besides guns on the upper deck; vessels of the lower classes carry their guns on the upper or open deck.

Fine sailing ships have gone upwards of 13 knots (or sea miles of 6080 feet) an hour, in a squall; and upwards of 10 knots on a bow line, that is, the sails being sharply trimmed when the direction of the wind makes an angle of about 67° with that of the ship's head.

The principal scientific works on ships are, Bouguer, *Traité du Navire;* Euler, *Scientia Navalis;* Id. *Théorie de la Construction et de la Manœuvre des Vaisseaux;* Don George Juan, *Examen Maritimo*, and a French translation, with notes, by L'Eveque; *Chapman's Naval Architecture*, &c. Much general information is to be found in *Charnock's Marine Architecture*, and many other works contained in any good catalogue, under the heads Naval Architecture, Seamanship, especially in *Darcy Lever's Seamanship*, &c. But the subject has as yet been but imperfectly treated, and many points of great practical importance, and unconnected with the particular properties of fluids, have not been discussed.

SHIP, ARMED. In the English usages of war, a private vessel occasionally taken into the service of government in time of war, armed and equipped like a regular ship of war, and commanded by an officer of the navy, with the rank of master and commander.

SHIP-BUILDING. *See* Naval Architecture.

SHIP MONEY. The celebrated tax imposed by Charles I. without authority of parliament, which proved one of the most immediate causes of the discontents that ended in the great rebellion. This device was first put in practice in 1634. It was by a writ, directed to the sheriff of every county, to provide a ship for the king's service; accompanied by written instructions, appointing a sum of money to be levied instead. This writ was framed by Attorney-General Noy. The tax was paid for about four years without opposition; when the question of its legality was raised by the refusal of Hampden to pay his share. It was argued before the judges in the Exchequer Chamber, of whom a great majority gave judgment for the crown. The act "whereby all the proceedings in the business of ship-money were adjudged void, and disannulled, and the judgments, enrolments, and entries thereupon vacated and cancelled," was one of the first proceedings of the Long Parliament. (See *Clarendon*, books i. iii.)

SHIPS, REGISTRY OF. In Commercial Navigation, the registration or enrolment of ships at the custom-house, so as to entitle them to be classed among, and to enjoy the privileges of, British-built ships.

The registry of ships appears to have been first introduced into this country by the Navigation Act (12 Car. 2. c. 18. anno 1660). Several provisions were made with respect to it by the 7 & 8 Will. 3. c. 22.; and the whole was reduced into a system by the 27 Geo. 3. c. 19.

It may be laid down in general, that a vessel, in order to be admitted to registry, and consequently to enjoy the privileges and advantages that exclusively belong to a British ship, must be the property of his Majesty's subjects in the United Kingdom or some of its dependencies; and that it must have been built in the said United Kingdom, &c., or been a prize vessel legally condemned, or a vessel legally condemned for a breach of the slave laws.

The great, and perhaps the only original object of the registration of ships, was to facilitate the exclusion of foreign ships from those departments in which they were prohibited from engaging by the navigation laws, by affording a ready means of distinguishing such as were really British. It has also been considered advantageous to individuals, by preventing the fraudulent assignment of property in ships; but Lord Tenterden has observed, in reference to this supposed advantage, that "the instances in which fair and honest transactions are rendered unavailable, through a negligent want of compliance with the forms directed by these and other statutes requiring a public register of conveyances, make the expediency of all such regulations, considered with reference to private benefit only, a matter of question and controversy." (*Law of Shipping*, part i. c. 2.)

SHIPWRECK, in the open sea, arises from the water leaking in at the bottom of a ship faster than the pumps can discharge it; or from the sea coming over one of the decks, and getting below in great quantity; or from the vessel being overset by the wind. In the labouring of a weak ship in a heavy sea the seams of the sides and bottom open, and the caulking works loosen. When the loss of a mast occurs, the ship is often left entirely to the action of the waves. People unused to the sea look with admiration on the strength and solidity of a ship; but those who have experienced the violent shocks of the waves, and are conversant with the effects of incessant agitation upon any fabric, and the straining effects of the masts and sails on the hull, are rather surprised that such a machine should hold together for so many years.

When the ship is wrecked near the shore, the object is to land the crew. The first method proposed was, we

believe, Bell's, in 1791. A mortar was fired from the ship, carrying a shell with a rope attached, by which communication with the shore might be established. Captain Manby, in 1808, employed the mortar on shore, where alone, it is obvious, its action could be depended upon; and methods have since been adopted for winding the rope on a cone for disengaging it without impediment, which had been found the chief difficulty.

SHIRE. A territorial division. (From the Anglo-Saxon scyran, *to divide;* whence the verb *to sheer.*) In modern language, shire is synonymous with county; but some smaller districts in the north of England retain the provincial appellation of shires: as Richmondshire, in the North Riding of Yorkshire; Hallamshire, or the manor of Hallam, in the West Riding, which is nearly coextensive with the parish of Sheffield. *See* COUNTY.

SHIRE CLERK. An officer appointed by the sheriff to assist in keeping the county court.

SHIRE MOTE. The Shire Meeting; *i. e.* sheriff's court.

SHOOTING STARS. Well-known meteors, of which the origin and nature are involved in great obscurity, and which have, of late years, excited extraordinary interest by their periodical appearances in unusually great numbers.

Phenomena of Shooting Stars. — The apparent magnitudes of these meteors are widely different. The greater part of them resemble stars of the 3d, 4th, 5th, and 6th magnitudes; but some occur which surpass stars of the 1st magnitude, and even exceed Jupiter and Venus in brilliancy. In some of them the globular form can be easily recognized: these are, in every respect, similar to *bolides* or *fire-balls;* and, in fact, it is impossible, from their appearances, to make any distinction between the larger shooting stars and the smaller individuals of the class of meteors to which the name of fire-balls is usually appropriated. *See* FIRE-BALLS.

Shooting stars appear to be equally numerous in every climate. The weather seems to have no influence upon their number. They are observed at all times of the year; but, generally speaking, they appear to be more abundant in the end of summer and autumn than at the other seasons.

Some of the shooting stars leave a luminous train behind them, which marks their path through the sky with a milk-white light. These trains for the most part disappear in a few seconds; but sometimes they continue longer, and even for several minutes. In the case of actual fire-balls, Dr. Olbers observed trains which continued from six to seven minutes; and Brandes, in one instance, estimated that fifteen minutes elapsed between the extinction of the fire-ball and the disappearance of the luminous train. The trains in general assume the form of a cylinder, the interior of which is void of luminous matter; and not unfrequently, before their disappearance, they take a curved form. The most probable explanation is, that they are caused by a gaseous matter left behind by the meteor, and bent by currents of air.

The older philosophers had formed various theories to explain these remarkable phenomena. By some they were supposed to be the products of an oily sulphurous vapour existing in the atmosphere, which being disposed in thin layers, and becoming inflamed by some means, would exhibit the appearance of a clear brilliant spark passing rapidly from one point to another. About the middle of the last century, when the effects and phenomena of electricity began to be better understood, Beccaria and Vassali, among others, regarded the shooting stars as merely electrical sparks; an hypothesis which was soon shown to be untenable. At a later period, when the inflammable nature of the gases became known, Lavoisier, Volta, Herbert, Toaldo, Gren, and others, referred these meteors to hydrogen gas, which, by reason of its inferior density, they supposed must be accumulated in the higher regions of the atmosphere. Dalton, however, showed that such accumulation cannot take place, inasmuch as all the gases which constitute the atmosphere must be equally diffused through its whole extent, according to the law of Mariotte. Deluc maintained that certain phosphoric exhalations generated in the earth, and becoming inflamed in the sky, formed the true essence of the shooting stars.

In this state the subject remained when Chladni published his celebrated work on the causes of the masses of iron and other similar substances found in Siberia by Pallas, in which he clearly established, by comparing the circumstances of a great multitude of observations, that the fire-balls are meteors having their origin beyond our atmosphere; that, in fact, they are masses of nebulous matter moving in space with planetary velocities, which, when they come in the way of the earth in its revolution about the sun, and enter the atmosphere, are inflamed by its resistance and friction, and become luminous, sometimes scattering masses of stone and iron on the ground. Halley, Wallis, Pringle, Maskelyne, and others, had previously assigned a cosmical origin to these meteors, but without suspecting that masses of stone and iron fell from them. The close resemblance which the greater part of the shooting stars present to fire-balls, at once induced Chladni to consider these phenomena also as cosmical; that is to say, as small masses of matter not having their origin in our atmosphere, but entering it from without, and which are either entirely consumed in it, or become extinguished when they have passed beyond it.

These conclusions, however, required to be confirmed by a more accurate investigation of the phenomena; for as yet no exact determination had been made of the actual average heights of the shooting stars above the earth, or of their orbits, velocities, or magnitudes. In the year 1798 this important but difficult inquiry was undertaken by Professors Brandes of Leipsig, and Benzenberg of Düsseldorf (both at that time students in Göttingen). Having selected a base line (about nine miles in length), they placed themselves at its extremities on appointed nights, and observed all the shooting stars which appeared, tracing their courses through the heavens on a celestial map, and noting the instants of their appearances and extinctions by chronometers previously compared. The differences of the paths traced on the maps afforded data for the determination of the parallaxes, and consequently the heights and the lengths of the orbits. On six evenings, between September and November, the whole number of shooting stars seen by both observers was 402; of these 22 were identified as having been observed by each in such a manner that the altitude of the meteor above the ground at the instant of extinction could be computed. The least of the altitudes was about 6 English miles. Of the whole there were 7 under 45 miles; 9 between 45 and 90; 6 above 90; and the highest was above 140 miles. There were only two observed so completely as to afford data for determining the velocity. The first gave 25 miles, and the second from 17 to 21 miles in a second. The most remarkable result was, that one of them certainly was observed not to *fall*, but to move in a direction away from the earth.

By these observations a precise idea was first obtained of the altitudes, distances, and velocities of these singular meteors. A similar but more extended plan of observation was organized by Brandes in 1823, and carried into effect at Breslau and the neighbouring towns by a considerable number of persons observing at the same time on concerted nights. Between April and October about 1800 shooting stars were noted at the different places; out of which number 62 were found which had been observed simultaneously at more than one station in such a manner that their respective altitudes could be determined, and 36 others of which the observations furnished data for estimating the entire orbits. Of these 98, the heights (at the time of extinction) of 4 were computed to be under 15 English miles; of 15 between 15 and 30 miles; of 22 between 30 and 45; of 33 between 45 and 70; of 13 between 70 and 90; and of 11 above 90 miles. Of these last two had an altitude of about 140 miles, one of 220 miles, one of 280, and there was one of which the height was estimated to exceed 460 miles.

Of the 36 computed orbits, in 26 instances the motion was downwards, in one case horizontal, and in the remaining 9 more or less upwards. The velocities were between 18 and 36 miles in a second. The trajectories were frequently not straight lines, but incurvated sometimes in the horizontal and sometimes in the vertical direction, and sometimes they were of a serpentine form. The predominating direction of the motion of the meteors from north-east to south-west, contrary to that of the earth in its orbit, was very remarkable, and is important in reference to their physical theory.

A similar set of observations was made in Belgium in 1824, under the direction of M. Quetelet, the results of which are published in the *Annuaire de Bruxelles* for 1837. M. Quetelet was chiefly solicitous to determine the velocity of the meteors. He obtained six corresponding observations from which this element could be deduced, and the results varied from ten to twenty-five English miles in a second. The mean of the six results gave a velocity of nearly seventeen miles per second, a little less than that of the earth in its orbit.

Another set of corresponding observations was made in Switzerland on the 10th of August, 1838; a circumstantial account of which is given by M. Wartmann in *Quetelet's Correspondance Mathématique*, for July, 1839. M. Wartmann and five other observers, provided with celestial charts, stationed themselves at the observatory of Geneva; and the corresponding observations were made at Planchettes, a village about sixty miles to the north-east of that city. In the space of seven and a half hours, the number of meteors observed by the six observers at Geneva was 381; and during five and a half hours, the number observed at Planchettes by two observers was 104. All the circumstances of the phenomena — the place of the apparition and disappearance of each meteor, the time it continued visible, its brightness relatively to the fixed stars, whether accompanied with a train, &c. — were carefully noted, and the trajectories projected on a large

planisphere. The extent of the trajectories described by the meteors was very different, varying from 8° to 70° of angular space. The velocities appeared also to differ considerably; but the average velocity was supposed by M. Wartmann to be 25° per second. It was found, from the comparison of the simultaneous observations, that the average height above the ground was about 550 miles; and hence the relative velocity was computed to be about 240 miles in a second. But as the greater number moved in a direction opposite to that of the earth in its orbit, the relative velocity must be diminished by the earth's velocity (about 19 miles in a second). This still leaves upwards of 220 miles per second for the absolute velocity of the meteor, which is more than eleven times the orbital velocity of the earth, seven and a half times that of the planet Mercury, and probably greater than that of the comets at their perihelia.

Such are the principal facts which have yet been established respecting the heights, velocities, and orbits of the shooting stars; and it is from these chiefly that we are enabled to form any probable conjectures respecting their origin. And since it is now established that no difference is observable between the larger shooting stars and small fire-balls, both having similar altitudes and velocities, and presenting absolutely the same appearances, we may assume them to be of the same nature, and that whatever has been proved respecting fire-balls will apply equally to the larger shooting stars. Whether the meteoric appearances to which the latter term is applied may not include objects of totally different natures, is a question admitting of doubt. It is possible that among the shooting stars there may be objects which are merely electric sparks, or which have their origin in spontaneously inflammable gases, known or unknown, existing in the atmosphere; but the greater part of them must be considered as identical with fire-balls.

Physical Theory of the Shooting Stars. — Some philosophers, as already stated, have ascribed an atmospheric origin both to the shooting stars and fire-balls; but the observations of Brandes, and more particularly those of Wartmann, which prove that many of them appear at altitudes far beyond the limits which can be assigned with any probability to the atmosphere, have rendered this supposition altogether untenable. Another hypothesis respecting their origin is, that they are bodies projected to our earth from volcanoes in the moon. Dr. Olbers was the first, perhaps, who showed the possibility of this hypothesis. On computing the forces necessary to overcome the moon's attraction, he found that a body projected from the moon with a velocity of about 8500 feet in a second would not fall back on the lunar surface, but recede from it indefinitely; and that in order to reach the earth it is only necessary that the projectile should have the velocity of 8300 feet, which is quite conceivable, being only about four or five times that of a cannon ball. The hypothesis of the lunar origin of meteoric stones was adopted by Laplace, Berzelius, Benzenberg, and others; but the observed velocities of the shooting stars have rendered this origin extremely improbable with respect to them. In order to enter our atmosphere with a velocity of 20 miles in a second, it may be shown that if they come from the moon they must have been projected from the lunar surface with a velocity of about 120,000 feet in a second, which may be regarded as altogether impossible.

It thus appears that those shooting stars and fire-balls which have the planetary velocity of from 20 to 40 miles in a second, cannot with any probability be regarded as having their origin in the moon. Whether any individual bodies moving with a smaller velocity may have a lunar origin, is a question which cannot be decisively answered. "To me," says Dr. Olbers, "it does not appear at all probable; and I regard the moon, in its present circumstances, as an extremely peaceable neighbour, which, from its want of water and atmosphere, is no longer capable of any strong explosions."

The hypothesis first suggested by Chladni is that which appears to have met with most favour, having been adopted by Arago and other eminent astronomers of the present day to explain the November phenomena. It consists in supposing that, independently of the great planets, there exist in the planetary regions myriads of of small bodies which circulate about the sun, generally in groups of zones; and that some of these zones intersect the ecliptic, and are consequently encountered by the earth in its annual revolution. The principal difficulties attending this theory are the following: — First, that bodies moving in groups in the circumstances supposed must necessarily move in the same direction, and consequently, when they become visible from the earth, would all appear to emanate from one point and move towards the opposite. Now, although the observations seem to show that the predominating direction is from north-east to south-west, yet shooting stars are observed on the same nights to emanate from all points of the heavens, and to move in all possible directions. Secondly, their average velocity (especially as determined by Wartmann) greatly exceeds that which any body circulating about the sun can have at the distance of the earth. Thirdly, from their appearance, and the luminous train which they generally leave behind them, and which often remains visible for several seconds, sometimes for whole minutes, and also from their being situated within the earth's shadow, and at heights far exceeding those at which the atmosphere can be supposed capable of supporting combustion, it is manifest that their light is not reflected from the sun; they must therefore be self-luminous, which is contrary to every analogy of the solar system. Fourthly, if masses of solid matter approached so near the earth as many of the shooting stars do, some of them would inevitably be attracted to it; but of the thousands of shooting stars which have been observed, there is no authenticated instance of any one having actually reached the earth. Fifthly, instead of the meteors being attracted to the earth, some of them are observed actually to rise upwards, and to describe orbits which are convex towards the earth; a circumstance of which, on the present hypothesis, it seems difficult to give any rational explanation.

From the difficulties attending every hypothesis which has hitherto been proposed, it may be inferred how very little real knowledge has yet been obtained respecting the nature of the shooting stars. It is certain that they appear at great altitudes above the earth, and that they move with prodigious velocity; but every thing else respecting them is involved in profound mystery. From the whole of the facts, M. Wartmann thinks that the most rational conclusion we can adopt is, that the meteors probably owe their origin to the disengagement of electricity, or of some analogous matter, which takes place in the celestial regions on every occasion in which the conditions necessary for the production of the phenomena are renewed.

The presumptions in favour of the cosmical origin of the shooting stars are chiefly founded on their periodical recurrence at certain epochs of the year, and the extraordinary displays of the phenomena in various years on the nights of the 12th or 13th of November. We shall here merely state the principal circumstances accompanying those of 1799, which put the notion of a *lunar* origin entirely out of the question.

On the morning of the 12th of November, 1799, before sunrise, Humboldt and Bonpland, then on the coast of Mexico, were witnesses to a remarkable exhibition of shooting stars and fire-balls. They filled the part of the heavens extending from due east to about 30° towards the north and south. They rose from the horizon between the east and east-north-east points, described arcs of unequal magnitude, and fell towards the south; some of them rose to the height of 40°, all above 25° or 30°. Many of them appeared to explode, but the larger number disappeared without emitting sparks: some had a nucleus apparently equal to Jupiter. This most remarkable spectacle was seen at the same time in Cumana, on the borders of Brazil, in French Guiana, in the channel of Bahama, on the continent of North America, in Labrador, and in Greenland; and even at Carlsruhe, Halle, and other places in Germany, many shooting stars were seen on the same day. At Nain and Hoffenthal in Labrador, and at Neuhernhut and Lichtenau in Greenland, the meteors seem to have approached the nearest to the earth. At Nain they fell towards all points of the horizon; and some of them had a diameter which the spectators estimated at half an ell. (See *Humboldt's Recueil des Voyages, &c.* vol. ii.)

Under the term FIRE-BALLS, the reader will find an account of a not less stupendous exhibition which took place in North America on the night of the 12th of November, 1833. In 1834, a similar phenomenon occurred on the night of the 13th of November; but on this occasion the meteors were of a smaller size. In 1835, 1836, and 1838, shooting stars were observed on the night of November 13th in different parts of the world; but though diligently looked for on the same nights in 1839 and 1840, they do not appear to have been more numerous than on other nights about the same season of the year.

The second great meteoric epoch is the 10th of August, first pointed out by M. Quetelet; and although no displays similar to those of the November period have been witnessed on this night, there are more instances of the recurrence of the phenomena. In the last three years (1838, 1839, 1840), shooting stars were observed in great numbers both on the 9th and 10th; but they appear in general to be unusually abundant during the two first weeks of August. The other periods which have been remarked are the 18th of October, the 23d or 24th of April, the 6th and 7th of December, the nights from the 15th to the 20th of June, and the 2d of January.

Halley first suggested the idea that the shooting stars may be observed as signals for determining differences of longitude by simultaneous observations; and Maskelyne in 1783 published a paper on the subject, in which he calls the attention of astronomers to the phenomena, and distinctly points out this application. The idea was revived by Benzenberg in 1802; but so long as they were

regarded merely as casual phenomena, it could scarcely be hoped that they would be of much use in this respect to practical astronomy. As soon, however, as their periodicity became probable, the phenomena acquired a new interest; and some recent attempts to determine longitudes in this manner have proved that the method is not to be disregarded. (*Monthly Notices of the R. Astr. Society for January*, 1841.)

See an interesting paper on this subject by Dr. Olbers, in *Schumacher's Jahrbuch* for 1837; also the *Annuaire du Bureau des Longitudes* for 1836; *Mem. de l'Academie de Bruxelles* for 1838; *Schumacher's Astronomisches Nachrichten*, vols. xvi. and xvii.; and the various Scientific Journals.

SHORE. In Architecture, a piece of timber or other material placed in such a direction as to prop up a wall or other heavy body.

SHOT. Any kind of missile discharged by an instrument; but the term usually denotes balls for fire-arms.

SHOT LOCKERS. Long pieces of wood pierced with holes like cups, in which the shot are placed, along the sides and round the hatchways.

SHOU'LDER. In Fortification, the angle of a bastion included between the face and flank.

SHO'VELER. The name of a species of duck, remarkable for the length and terminal expansion of the bill; whence the name of *Spathulea*, proposed for the subgenus of which it is the type. It is the *Anus clypcata* of Linnæus.

SHRA'PNELL SHELLS, in Gunnery, are shells filled with a quantity of musket balls, which, when the shell explodes, are projected about 150 yards further. They are fired from guns, mortars, and howitzers, and have been found most effective. A six-pounder spherical case contains twenty-seven musket balls, which, when the shell explodes, do as much injury as an equal number of muskets, at a distance far beyond the reach of musketry. (*Ency. Brit.* art. "Gunnery.")

SHREW. *See* SOREX.

SHRIKE. A name for the *butcher birds*, or species of *Laniaries*.

SHRINE. (Lat. scrinium, *a desk or cabinet;* whence also *screen.*) Properly, the receptacle of the remains or relics of a saint. Shrines are of two sorts: portable, used in processions, called in Latin *feretra;* and fixed, in churches. The appropriate place for shrines, in the churches of the middle ages, was generally in the eastern part, in the space behind the high altar. Such is the situation of the celebrated shrine of the three kings of Cologne; and such was that of the shrines at St. Alban's, Canterbury, Durham, and Westminster, before the Reformation. (*Archæologia*, vol. i.)

SHROUDS. The large ropes supporting a mast laterally; they take the names of their respective masts, as the lower main shrouds, &c.

SHROVE TUESDAY. The Tuesday after Quinquagesima Sunday, and immediately preceding Ash Wednesday; so called from the Sax. shriven, *to confess*, because on that day confession was made preparatory to the fast of Lent. The custom of ringing the bells for this occasion was long retained in many parishes, particularly in London; although the vulgar name of "pancake bell" shows that little was left of the solemnity beyond the dinner on pancakes which followed it. See *Brand's Popular Antiquities*, for an account of the various shrovetide or carnival amusements of this country.

SHRUB. A small low dwarfish tree, which, instead of one single stem, frequently puts forth from the same root several sets or stems.

Shrub is also the name given to a species of sweet wine or liqueur, of which rum forms the chief ingredient.

SHUTTLE. An instrument used by weavers, which guides the thread it contains, so as to make it form the woofs of stuffs, cloths, linen, and other fabrics, by throwing the shuttle alternately from left to right and from right to left across between the threads of the warp, which are stretched out lengthwise on the loom. In the middle of the shuttle is a kind of cavity, called its eye or chamber, in which is enclosed the *spoul*, which is part of the thread destined for the woof.

SHWAN PAN. The calculating instrument of the Chinese. It is similar in shape and construction to the Roman abacus, and is used in the same manner. *Sec* ABACUS.

SI. In Music, the name for the seventh sound, added by Le Maire, a Frenchman, at the latter end of the 17th century, to the six ancient notes, ut, re, mi, fa, sol, la, of Guido; by means whereof, some authors say, much inconvenience in the ancient gamut is avoided.

SI'ALAGOGUE. (Gr. σιαλον, *saliva*, and αγωγος, *a leader.*) Medicines which increase the flow of saliva.

SIBE'RITE. A mineralogical synonym of rubellite or red tourmaline, the finest specimens of which have been found in Siberia.

SI'BYL. The name given to certain prophetic women said to have lived in early ages in Greece and Italy. Some authors recount as many as ten of them. The most celebrated were the Sibyl of Cumæ, fabled to have been consulted by Æneas, and the prophetess who offered her books to Tarquin the Proud. (See, among many authorities, the *Mém. de l'Ac. des Inscr.* vol. xxiii.)

SI'BYLLINE BOOKS. Documents supposed to contain the fate of the Roman empire. Nine of them are said to have been offered by an old woman, called Amalthæa, to Tarquin the Proud; but Tarquin refusing to give the price she asked, she went away, and burnt three of them. Returning with the remainder, she offered them to the king on the same terms as before; and on his second refusal departed again, and returned with three, which she still offered at the same price as the original nine. The king, struck with her conduct, at last acceded to her offer, and entrusted the care of the books to certain priests (the quindecemviri). They were preserved in a stone chest beneath the temple of Jupiter Capitolinus, and were consulted in times of public danger or calamity. They were destroyed by the fire that consumed the Capitol in the Marsic war. After this calamity, ambassadors were sent to collect such fragments of Sibylline prophecies as they could pick up in various countries; and from the verses thus collected Augustus formed two new books, which were deposited in two gilt cases in the temple of the Palatine Apollo. Sibylline verses are often quoted by Christian writers, as containing prophecies of Christianity; but these are spurious, a forgery of the 2d century.

SICI'LIAN VE'SPERS. In Modern History, the name commonly given to the great massacre of the French in Sicily, in A. D. 1282. They were the soldiers and subjects of Charles of Anjou, who had made himself master of the island after the defeat and death of Conradin. The insurrection broke out on the evening of Easter Tuesday, whence the name. Its consequence was the expulsion of Charles; and the islanders placed themselves under the protection of the king of Arragon.

SIDE'REAL. (Lat. sidus, *a star.*) Something relating to the stars.

The *sidereal day* is the time in which the earth makes a complete revolution on its axis, in respect of the fixed stars or any fixed point in space. (*See* DAY.) "If the sidereal day be taken equal to 24 sidereal hours, the mean solar day will be equal to 24 h. 3 m. 56·55 sec. of those hours; and if the mean solar day be taken equal to 24 mean solar hours, the sidereal day will be equal to 23 h. 56 m. 4·09 sec. of those hours. Or, in all cases, if we wish to determine, in sidereal time, the value of any given interval expressed in mean solar time, and *vice versâ*, we shall have

$$\text{sidereal time} = 1{\cdot}00273791 \times \text{mean solar time},$$
$$\text{mean solar time} = 0{\cdot}99726957 \times \text{sidereal time.}\text{"}$$

(*Baily's Astronomical Tables*, 1827.)

The *sidereal year* is the time in which the earth performs a complete revolution, relatively to the fixed stars, in its orbit; namely, 365·2563612 mean solar days, or 365 d. 6 h. 9 m. 9·6 sec., being 20 m. 19·9 sec. longer than the tropical year. *See* YEAR.

SIDE'ROCALCITE. (Gr. σιδηρος, *iron;* Lat. calx, *lime.*) The name given by Kirwan to the *brown spar* of Werner.

SIENITE, or SYENITE. (From Syene in Egypt, whence the Romans obtained it for architectural purposes.) A granitic aggregate of quartz, felspar, and hornblende. *See* GEOLOGY.

SIERRA. A Spanish term, signifying a chain of hills, and prefixed to the names of several places in Spain, and other parts discovered or colonized by the Spaniards.

SIESTA. (Span.) The name given to the practice indulged in by the Spaniards, and the inhabitants of hot climates generally, of resting two or three hours in the middle of the day, when the heat is too oppressive to admit of their going from home.

SIGILLA'RIA. Fossil plants found in the coal formation.

SIGN. In Algebra, a symbol indicating an operation to be performed, or a relation subsisting between two quantities. Of the former kind, those most commonly used are, $+$ for addition, $-$ for subtraction, $\times$ for multiplication, $\div$ for division, $\sqrt{}$ for the square root, $\sqrt[3]{}$ for the cube root, $\sqrt[n]{}$ for the *n*th root, &c. The signs denoting a relation are, $=$ equal to, $>$ greater than, $<$ less than, &c.

SIGN. In Astronomy, a portion of the ecliptic or zodiac, containing thirty degrees, or a twelfth part of the complete circle. The first commences at the point of the equator through which the sun passes at the time of the vernal equinox; and they are counted onwards, proceeding from west to east, according to the annual course of the sun, all round the circle. The names of the twelve signs, in the order in which they follow each other, with the characters by which they are indicated on globes, and in the almanacs and books of astronomy, are as follows:— *Aries* ♈, *Taurus* ♉, *Gemini* ♊, *Cancer* ♋, *Leo* ♌, *Virgo* ♍, *Libra* ♎, *Scorpio* ♏, *Sagittarius* ♐, *Capricornus* ♑, *Aquarius* ♒, *Pisces* ♓.

It is to be remarked, that the above are also the names

of the twelve constellations of the zodiac; and in ancient times (above 200 years before our era), the places of the signs and the constellations were coincident; but owing to the motion of the earth's equator, by which the equinoctial points are carried backwards on the ecliptic about 50·6″ annually, the intersections of the ecliptic and equator, and consequently the commencement of the signs, now correspond to different stars, the first point of the sign Aries being at present near the beginning of the constellation Pisces. On this account care must be taken not to confound the signs of the zodiac, which are fixed in respect of the equinoxes, with the constellations, which are moveable in respect of those points. *See* CONSTELLATION.

The *ascending signs* are the six beginning with Capricornus, through which the sun passes while advancing from the winter to the summer solstice, and is, consequently, acquiring altitude with respect to inhabitants of the northern hemisphere. The other six, beginning with Cancer, are called the *descending signs*.

SI'GNALS, NA'VAL, imply a system of symbols addressed to the eye, as flags, boards, lights, &c., for establishing communication at distances too great for the voice. Guns are also used for the same purposes. The first signals seem to have been merely distinguishing flags for certain ships. In the system of signals instituted by James II. for orders to the fleet, the purport depended on the part of the ship at which they were exhibited; a condition very detrimental to the use of signals at sea. A code composed of *numeral* flags and pendants, *i. e.* in which each symbol had a number assigned to it, seems to have been the first step towards a general system, as before this plan each admiral instituted his own code. In 1815, Sir Home Popham's code was adopted. This added several *literal* or alphabetical flags and pendants, which greatly extended the means of communication, but necessarily rendered the signals indistinct, and their purports deceitful, in many cases, from the increased difficulty of distinguishing each flag from the rest. In 1826, in consequence of some plans having been submitted by admirals for a more efficient system, the code now in use, which is considered as an improvement on its predecessor, was adopted. In 1828, Admiral Raper published his code, which was one of those under consideration. The principle of this system, which is undeviatingly adhered to, is, that the manner of combination of the flags and pendants of which the signal is composed *i. e.* their order or arrangement, points out the subject of the signal, or, as the author terms it, the *point of service* to which the signal relates; while the *numbers* of the individual symbols indicate the number of the signal in its class. The numbers are denoted, as usual, by the colours; but when these fail, from haze or distance, the number is supplied by *numeral distant signals*. From the distinctness attending the small number of symbols (the smallest possible for complete numeral signals), the precision obtained from classification by which the simplicity of each signal is proportioned to its importance, and the saving of the time often wasted in vain attempts to distinguish the precise disposition of the colours of each flag, this system has been considered by some competent judges as the sole thoroughly efficient method.

In the merchant service, signals are of less extensive utility than in the royal navy, their chief employment being to express the names of vessels, latitude and longitude, and a few other such particulars; and it were much to be desired that governments would agree to establish universal signals on like points of general interest. The code in use is Captain Marryatt's.

Ingenious systems have been published by Lieut. C. Phillips, R. N., for the ships of all nations; and also by Admiral Sir C. Ekins, entitled *Universal Signals*, the symbols being black and white only. From what little acquaintance we have had with foreign signals, we consider them by no means in advance of our own.

SIG'NATURE. (Lat. signatura.) In Music, the flats and sharps placed after the clef, at the beginning of the staff, which affect, throughout the movement, all notes of the same letter.

SIGNATURE. In Printing, a letter of the alphabet placed at the bottom of the first page of each sheet of a work, to denote, alphabetically, the order of the sheets.

It is customary to commence with B on the first sheet of the body of the work, and to go regularly through the alphabet, with the exception of the letters J, V, and W, which are never used as signatures; and which had, in fact, no existence in the alphabet at the time of the invention of printing; 𝔍, expressing both I and J; 𝔘, both U and V; and 𝔘𝔘, the double letter W. If the work extend to more sheets in number than there are letters in the alphabet, the succeeding sheets go on with a second alphabet, which commences with A, and both the letters are usually given; in this manner, A A, or A a, and sometimes, to avoid the repetition, thus, 2 A. If a third alphabet be necessary, it is always, at the present day, placed with the number before it, as 3 A. The printer's first alphabet consists of twenty-two letters, and the second and succeeding ones of twenty-three.

As a guide to the bookbinder, there are other signatures used in a sheet besides the first. In a sheet of octavo the first page has B, the third has B 2, the fifth has B 3, and the seventh has B 4: in a sheet of twelves they are carried to B 6, B 5 being the first page of the offcut; and however numerous the pages may be in a sheet with one signature, when they are all inserted, they are continued to the last odd page before the middle of the sheet, but never carried beyond the middle. In general they are all omitted except the two first, to show the first fold of the paper, and the first on the offcut. Small capitals are more frequently used for signatures than large capitals, as disfiguring the foot of the page in a slighter manner. Sometimes figures are used instead of letters, but not often; the *Gentleman's Magazine* is an instance. (*Savage's Dict. of Printing.*)

SI'GNET, THE PRIVY. One of the king's seals in England, used in sealing private letters and grants under the sign manual. It is in the custody of the Secretary of State for the Home Department. (*See* SEAL, SECRETARY.) The signet in Scotland is the seal by which the king's letters and writs for the purpose of justice are now authenticated. Hence the title of clerks to the signet, or writers to the signet; whose business is nearly the same with that of attorneys in England. They were anciently clerks in the office of the Secretary of State, by whom writs were prepared; and when the signet became employed in judicial proceedings, they obtained a monopoly of the privileges of acting as agents or attorneys before the Court of Session.

SIGN MANUAL. The royal signature, superscribed at the top of bills of grants or letters patent; which are then sealed with the privy signet or great seal, as the case may be, to complete their validity. But there are some grants which pass through certain offices, as the Admiralty or Treasury, under the sign manual only.

SIGNOR. The Italian term equivalent to the English *Lord*, *Sir*, or *Mr.*, the French *Monsieur*, and the German *Herr*. *Signoria* was anciently the appellation of the chief council of Venice, Genoa, and Lucca.

SILENA'CEÆ. (Silene, one of the genera.) An order of Polypetalous Exogenous plants, with opposite undivided leaves, and a stem with tumid nodes. The principal part of the order consists of uninteresting weedy plants; but it also contains the genera *Dianthus*, of which the garden pink, clove, and piccotee are species; the *Agrostemma*, *Saponaria*, and some other plants cultivated for their beautiful flowers.

SILE'NTIARY. Among the Romans, the title of office of a class of slaves attached to wealthy houses. In the court of the emperors, there was a body of officers attached to the household styled silentiaries. Thence the title came to functionaries of higher authority, and was borne by cabinet secretaries in the Lower Empire, and in the courts of Charlemagne and other western potentates who derived their code of ceremonial from Byzantium. Members of the privy council seem to have been sometimes called by this name under the Plantagenets in England.

SILE'NUS. (Gr. Σίληνος.) A Grecian divinity, the foster-father and attendant of Bacchus, and likewise leader of the satyrs. This deity was remarkable for his wisdom, his drunkenness being regarded as inspiration. He was represented as a robust old man in a state of intoxication, and riding on an ass, with a can in his hand. Silenus, says Mr. Bryant, is only a corruption of a masculine form of Σεληνη, *the moon*. By some speculative mythologists the drunken companion of Bacchus is converted into a sage, who was honoured as a dæmon after his decease. (*Theopompus in Ælian*, cited in Bryant, *Anc. Mythol.* vol. iii. p. 328.) There was an order of priests called Sileni, of the same class with the Curetes.

SI'LEX, or SI'LICA. (Gr. χαλις, *a pebble* or *stone*.) The earth of flints. This important substance constitutes the characteristic ingredient of a great variety of siliceous minerals; among which rock-crystal, quartz, chalcedony, and flint may be considered as silica nearly pure. It also predominates in many of the rocky masses which constitute the crust of our globe, such as granite, the varieties of sandstone, and quartz rock. Although silica has none of the ordinary or more obvious acid properties, yet, as it combines in definite proportion with many salifiable bases, and expels carbonic acid when fused with the carbonated alkalies, it is very commonly termed *silicic acid*, and its various compounds have been denominated *silicates*. When pure and colourless rock-crystal is heated red hot, and quenched in water, it becomes opaque and friable; and if in this state it be reduced to powder, it presents one form of pure silica. If in this state (in which it is perfectly insoluble in water) it be fused with three parts of carbonate of potash, it forms a glass which is soluble in water, and from this solution (formerly called *liquor of flints*) the concentrated acids throw down the silica in the form of a *gelatinous hydrate*; but if the solution be diluted, and the acid gradually added, the alkali may be

perfectly neutralized without any deposition of the silica, which, therefore, is thus exhibited in a very soluble state: when, however, the solution is evaporated to dryness, the silica remains in a state as insoluble as before. This solubility of hydrated silica, whilst when dry it is perfectly insoluble, may serve to explain the occasional occurrence of silica in mineral waters, and its deposition in various chalcedonic incrustations. But silica presents another very remarkable character; which is, that if we reverse the above proportions, and fuse together a mixture of one part of carbonate of potash and three of powdered rock-crystal or calcined flint, we then obtain a transparent and fusible compound, which is insoluble in water, and which, in fact, is glass.

Plate glass and *window glass*, or, as it is commonly called, *crown glass*, are silicates of soda or potassa; and *flint glass*, of which our common glass utensils are made, is a similar compound, with a large addition of silicate of lead. *See* Glass.

Silica, in its ordinary or *anhydrous* state, is insoluble in all acids except the *hydrofluoric*, which immediately acts upon it, and forms an extraordinary gaseous compound, the *fluosilicic* acid. Silica was long considered as an elementary form of matter; but Sir H. Davy found that when the vapour of potassium was brought into contact with pure silica heated to whiteness, silicate of potassa was formed, and a dark-coloured matter separated, which was afterwards found to be the base of silica, and to which the terms *silicium* and *silicon* have been applied. It is probably not metallic, and bears a greater analogy to boron than to any known principle. Silicon is a nonconductor of electricity, incombustible in air and oxygen, and not acted upon by any single acid; but it is readily soluble in a mixture of the nitric and hydrofluoric acids. It is, however, rapidly oxidized by and burns vividly at a temperature below redness, when in contact with fused soda or potassa. The exact equivalent of silica has not been very satisfactorily determined, but we are probably not very incorrect in regarding silica as a compound of equal weights of silicon and oxygen. In that case, if it be regarded as a protoxide, it is obvious that 8 will be the equivalent of its base, and silica will consist of 8 silicon + 8 oxygen, and be represented by the equivalent 16. But if silica be regarded as a compound of 1 atom of silicon and 3 atoms of oxygen, and Berzelius has shown that some analogies favour this view, then 24 will be its equivalent, and 48 that of silica. The *chloride of silicium*, and its *bromide*, are limpid fuming liquids; the former very volatile. The *sulphuret* is a white earthy-looking substance.

SILHOUETTE. In the Fine Arts, a name given to the representation of an object filled in of a black colour, and in which the inner parts are sometimes indicated by lines of a lighter colour, and shadows or extreme depths by the aid of a heightening of gum or other shining medium. This sort of drawing derives its name from its inventor, Etienne de Silhouette, the French minister of finance in 1759. Representations of this sort may be well enough taken from the shadow of a person thrown on a piece of paper placed against a flat surface or wall. The likeness may be still better taken, if on a reduced scale, by means of the instrument called a pantograph.

The invention of what is called a *silhouette* is, however, ascribed to a remote period, being said to have been the method whereby the daughter of a Greek potter drew the outline of her lover's portrait on a wall; and has been placed at the time of the renewal of the Olympic games, shortly before the expulsion of the Bacchiades from Corinth, about 776 B.C. It is to be observed that Sicyon and Corinth were the first cities in which painting flourished; and that Crato of Sicyon, Philocles of Egypt, and Cleanthes of Corinth, were considered the inventors of *monochromes*, or silhouettes, as they have been more recently called, which were applied to large objects. The Etruscan vases furnish to an amazing extent, and in boundless variety, some of the most beautifully drawn and elegant monochromes or silhouettes that have ever been executed.

SILI'CIFICÆ. Substances petrified or mineralized by siliceous earth.

SILI'CULA. (Lat. siliqua, *dim.*) A fruit exactly similar to that called a siliqua, except that it is shorter, and contains fewer seeds. It is never more than four times as long as broad, and usually much shorter.

SI'LIQUA. (Lat.) A one or two celled, many-seeded, linear fruit, dehiscent by two valves separating from a replum; the seeds are attached to two placentæ adhering to the replum, and opposite to the lobes of the stigma.

SILK. (Lat. sericum; from Seres, the supposed ancient name of the Chinese.) A fine glossy thread or filament spun by various species of caterpillars or larvæ of the *Phalæna* genus. Of these, the *Phalæna atlas* produces the greatest quantity; but the *Phalæna bombyx* is that commonly employed for this purpose in Europe. The silkworm, in its caterpillar state, which may be considered as the first stage of its existence, after acquiring its full growth (about three inches in length), proceeds to enclose itself in an oval-shaped ball, or cocoon, which is formed by an exceedingly slender and long filament of fine yellow silk, emitted from the stomach of the insect preparatory to its assuming the shape of the chrysalis or moth. In this latter stage, after emancipating itself from its silken prison, it seeks its mate, which has undergone a similar transformation; and in two or three days afterwards, the female having deposited her eggs (from 300 to 500 in number), both insects terminate their existence. According to Reaumur, the *phalæna* is not the only insect that affords this material, — several species of the *aranea*, or spider, enclose their eggs in very fine silk.

Raw silk is produced by the operation of winding off, at the same time, several of the balls or cocoons (which are immersed in hot water, to soften the natural gum on the filament) on a common reel, thereby forming one smooth even thread. When the skein is dry, it is taken from the reel and made up into hanks; but before it is fit for weaving, and in order to enable it to undergo the process of dyeing, without furring up or separating the fibres, it is converted into one of three forms, — viz. *singles*, *tram*, or *organzine*.

Singles (a collective noun) is formed of *one* of the reeled threads, being twisted, in order to give it strength and firmness.

Tram is formed of two or more threads twisted together. In this state it is commonly used in weaving, as the *shoot* or *weft*.

Thrown silk is formed of two, three, or more singles, according to the substance required, being twisted together in a contrary direction to that in which the singles of which it is composed are twisted. This process is termed *organzining;* and the silk so twisted, *organzine*. The art of throwing was originally confined to Italy, where it was kept a secret for a long period. Stowe says it was known in this country since the 5th of Queen Elizabeth, "when it was gained from the strangers;" and in that year (1562), the silk throwsters of the metropolis were united into a fellowship. They were incorporated in the year 1629; but the art continued to be very imperfect in England until 1719. (See *post.*)

1. *Historical Sketch of the Manufacture.* — The art of rearing silkworms, of unravelling the threads spun by them, and manufacturing the latter into articles of dress and ornament, seems to have been first practised by the Chinese. Virgil is the earliest of the Roman writers who has been supposed to allude to the production of silk in China, and the terms he employs show how little was then known at Rome as to the real nature of the article:—

> Velleraque ut foliis depectant tenuia Seres.
> *Georg.* book ii. lin. 121.

But it may be doubted whether Virgil do not, in this line, refer to cotton rather than silk. Pliny, however, has distinctly described the formation of silk by the *bombyx*. (*Hist. Nat.* lib. xi. c. 17.) It is uncertain when it first began to be introduced at Rome; but it was most probably in the age of Pompey and Julius Cæsar: the latter of whom displayed a profusion of silks in some of the magnificent theatrical spectacles with which he sought at once to conciliate and amuse the people. Owing principally, no doubt, to the great distance of China from Rome, and to the difficulties in the way of the intercourse with that country, which was carried on by land in caravans, whose route lay through the Persian empire, and partly, perhaps, to the high price of silk in China, its cost, when it arrived at Rome, was very great; so much so, that a given weight of silk was sometimes sold for an equal weight of gold! At first it was only used by a few ladies eminent for their rank and opulence. In the beginning of the reign of Tiberius, a law was passed —*ne vestis serica viros fœdaret* — that no man should disgrace himself by wearing a silken garment. (*Tacit. Annal.* lib. ii. c. 33.) But the profligate Heliogabalus despised this law, and was the first of the Roman emperors who wore a dress composed wholly of silk (*holosericum*). The example once set, the custom of wearing silk soon became general among the wealthy citizens of Rome, and throughout the provinces. According as the demand for the article increased, efforts were made to import larger quantities; and the price seems to have progressively declined from the reign of Aurelian. That this must have been the case, is obvious from the statement of Ammianus Marcellinus, that silk was, in his time (anno 370), very generally worn, even by the lowest classes: *Sericum ad usum antehac nobilium, nunc etiam infimorum sine ulla discretione proficiens.* (Lib. xviii. c. 6.)

China continued to draw considerable sums from the Roman empire in return for silk, now become indispensable to the western world, till the 6th century. About the year 550, two Persian monks, who had long resided in China, and made themselves acquainted with the mode of rearing the silkworm, encouraged by the gifts and promises of Justinian, succeeded in carrying the eggs of the insect to Constantinople. Under their direction they were hatched and fed; they lived and

laboured in a foreign climate; a sufficient number of butterflies were saved to propagate the race, and mulberry trees were planted to afford nourishment to the rising generations. A new and important branch of industry was thus established in Europe. Experience and reflection gradually corrected the errors of a new attempt; and the Sogdoite ambassadors acknowledged, in the succeeding reign, that the Romans were not inferior to the natives of China in the education of the insects, and the manufacture of silk. (Gibbon, *Decline and Fall*, vol. vii. p. 99.)

Greece, particularly the Peloponnesus, was early distinguished by the rearing of silkworms, and by the skill and success with which the inhabitants of Thebes, Corinth, and Argos carried on the manufacture. Until the 12th century, Greece continued to be the only European country in which these arts were practised; but the forces of Roger, king of Sicily, having, in 1147, sacked Corinth, Athens, and Thebes, carried off large numbers of the inhabitants to Palermo, who introduced the culture of the worm and the manufacture of silk into Sicily. From this island the art spread into Italy; and Venice, Milan, Florence, Lucca, &c. were soon after distinguished for their success in raising silkworms, and for the extent and beauty of their manufactures of silk. (*Gibbon*, vol. x. p. 110.; *Biographie Universelle*, art. "Roger II.")

The manufacture of silk appears to have been introduced into Spain at a very early period by the Moors, particularly in Murcia, Cordova, and Granada. "The last town, indeed, possessed a flourishing silk trade when it was taken by Ferdinand in the 15th century. The French having been supplied with workmen from Milan, commenced, in 1521, the silk manufacture; but it was not till 1564 that they began successfully to produce the silk itself, when Traucat, a working gardener at Nismes, formed the first nursery of white mulberry-trees, and with such success that in a few years he was enabled to propagate them over many of the southern provinces of France. Prior to this time, some French noblemen, on their return from the conquest of Naples, had introduced a few silkworms with the mulberry into Dauphiny; but the business had not prospered in their hands. The mulberry plantations were greatly encouraged by Henry IV.; and since then they have been the source of most beneficial employment to the French.

James I. was most solicitous to introduce the breeding of silkworms into England, and in a speech from the throne he earnestly recommended his subjects to plant mulberry-trees; but he totally failed in the project. This country does not seem to be well adapted to this species of husbandry, on account of the great prevalence of blighting east winds during the months of April and May, when the worms require a plentiful supply of mulberry-leaves. The manufacture of silk goods, however, made great progress during that king's peaceful and pompous reign. In 1629 it had become so considerable in London, that the silk throwsters of the city and suburbs were formed into a public corporation. So early as 1661 they employed 40,000 persons. The revocation of the edict of Nantes, in 1685, contributed in a remarkable manner to the increase of the English silk trade, by the influx of a large colony of skilful French weavers, who settled in Spitalfields. The great silk-throwing mill mounted at Derby, in 1719, also served to promote the extension of this branch of manufacture; for soon afterwards, in the year 1730, the English silk goods bore a higher price in Italy than those made by the Italians, according to the testimony of Keysler. It would be impossible, within our limits, to give an account of the gradual progress of the silk manufacture from that period down to the present time. Upon this subject, the reader will find ample details in the *Commercial Dictionary*; meantime we may remark, that a great revolution was effected in the manufacture in 1825. Previously to that epoch the legislative enactments with respect to it were the most contradictory and impolitic that can well be imagined. The importation of foreign silks was prohibited under the severest penalties; but the advantage that this prohibition was believed, though most erroneously, to confer on the manufacturer, would, under any circumstances, have been more than neutralized by the imposition of oppressive duties on the raw material. This vicious system was productive of a twofold mischief; for, by teaching the manufacturers to depend on custom-house regulations for protection against foreign competition, it made them indifferent about new discoveries and inventions, while, owing to the exorbitant duties on the raw material, and the want of improvement, the price of silks was maintained so high as to restrict the demand for them within comparatively narrow limits. In 1825, however, a new and more reasonable order of things was introduced. The duties on the raw material were greatly lowered; at the same time that foreign silk goods were allowed to be imported on payment of a duty of 30 per cent. *ad valorem*. This new system was vehemently opposed at its outset, and it was confidently predicted that it would occasion the ruin of the manufacture; but the result has shown the soundness of the principles on which it was bottomed. The manufacturers were now, for the first time, compelled to call all the resources of science and ingenuity to their aid; and the result has been that the manufacture has been more improved during the last dozen years than it had been in the whole previous century, and that it has continued progressively to increase.

The total quantity of raw silk imported for home consumption in 1838 was 3,595,816 lbs. The total number of individuals directly engaged in the manufacture has been estimated at upwards of 207,000; but we incline to think that this is very decidedly beyond the mark. The value of the silks annually produced may, perhaps, be estimated at from 10,000,000*l*. to 12,000,000*l*. (For full particulars as to the history and manufacture of silk, see Porter's treatise on the subject in *Lardner's Cyclopædia*.)

SILL. (Sax. ſyl.) In Architecture, the horizontal piece at the bottom of a framed case, such as that of a door or window. This word is also used to denote the bottom piece of a quarter partition. *Ground sills* are those timbers on the ground on which are placed the posts and superstructure of a timber building.

SI'LLIMANITE. A mineral named after Professor Silliman, from Saybrook in Connecticut; it is of a brown or dark grey colour, and composed of silica and alumina, with a trace of oxide of iron.

SILT. The name given to the sand, clay, and earth which accumulate in running waters.

SILU'RIAN. The name given by Murchison to a series of rocks forming the upper subdivision of the sedimentary strata found below the old red sandstone, and formerly designated the *greywacke series*. These strata are well developed in that part of England and Wales formerly included in the ancient British kingdom of the *Silures*. *See* GEOLOGY.

SILU'RIDANS, *Siluridæ*. (Lat. silurus, *a sheath-fish*.) The name of the family of fishes of which the genus *Silurus* is the type, and which includes the electric silurus (*Malapterurus electricus*). They are chiefly distinguished by the want of true scales, having merely a naked skin, or large osseous plates. A strong osseous spine forms the first ray of the dorsal and pectoral fins, except in the genus *Malapterurus*.

SILVA'NUS. A rural Italian deity; so called from Lat. sylva, *a wood*. He also presided over boundaries.

SI'LVER. (Germ. silber.) A white, malleable, ductile, and tenacious metal, of a brilliant lustre when polished, and soft when pure. Its specific gravity is 10·5. It is not altered by air or moisture, but is blackened or tarnished by sulphuretted hydrogen. When melted in open vessels it has the curious property of absorbing oxygen, which it gives out when it congeals. This is the cause of the appearance of granular crystallization which silver assumes when hastily cooled: a small *per-centage* of copper entirely prevents the effect. The only pure acids which act upon silver are the nitric and sulphuric. The nitric acid dissolves silver without the aid of heat, nitrous gas is evolved, and a dense colourless solution obtained, from which tabular crystals of nitrate of silver may be procured by evaporation. These crystals are anhydrous, and consist of 118 oxide of silver and 54 nitric acid, the equivalent of silver being 110. When melted, and cast into sticks or quills, they form the *lunar caustic* of the surgeons. Any gold which the silver might have contained, being insoluble in nitric acid, remains in the form of a black powder, and this simple process enables us readily to separate those metals. Silver is not attacked by cold sulphuric acid; but when granulated silver is heated in concentrated sulphuric acid, one portion of the acid is decomposed and imparts oxygen to the silver; sulphurous acid is evolved, and the oxide of silver dissolves in the residuary acid, forming a sulphate of silver. It is a difficultly soluble salt, forming anhydrous acicular crystals. In this case, the gold also remains undissolved; and as sulphuric is much cheaper than nitric acid, it is used for the separation of those metals upon the large scale. The solutions both of the nitrate and sulphate of silver are decomposed by the immersion of several of the other metals. Copper is generally used for the purpose; which, when immersed in the solution of silver, causes its separation in the form of a grey metallic powder, which is sometimes technically called *water silver*. Chlorine and all the soluble chlorides, when added to solutions of silver, occasion a white curdy precipitate, which is distinguished by the rapidity with which it blackens by exposure to light. The substance thus formed is a chloride of silver, composed of 110 silver + 36 chlorine, the equivalent of chloride of silver being 146. It is not decomposed by heat alone; but when carefully melted it concretes into a horny substance, formerly called *luna cornea*. Chloride of silver may be easily decomposed either by mixing it in a moist state with zinc filings, or by fusing it with carbonate of soda or potash: in either case metallic silver is obtained. The insolubility of chlo-

ride of silver renders a solution of nitrate of silver an admirable test of the presence of common salt or other chlorides in mineral waters; and, on the other hand, a solution of common salt is used to detect silver when in solution. A solution of two drachms of nitrate of silver in an ounce of water, coloured by a little sap green or Indian ink, forms marking ink; and when written upon linen, previously prepared by the application of a weak solution of carbonate of soda with a little starch or gum in it, soon forms black indelible letters. When a nitric solution of silver is mixed with alcohol, an effervescence ensues, and *fulminating silver* is precipitated. This most dangerous compound (a peculiar cyanate of silver) ought never to be meddled with in quantity, and always with the utmost circumspection; it explodes with violence upon the slightest friction of hard bodies, or when struck, rubbed, or heated.

The numerous uses and applications of silver are well known. In its pure state it is too soft for coin, plate, and most ornamental purposes, and is therefore, in such cases, alloyed with copper, by which, in proper proportion, its colour is not materially impaired, and it is considerably hardened. The standard silver of our coin is an alloy of 11 oz. 2 dwts. of pure silver, and 18 dwts. of copper, to the pound Troy; and this weight is coined into 66 shillings.

Silver is found *native*, and in the state of *sulphuret*, constituting the varieties of black and vitreous silver ore. It also occurs in combination with several other metals, and more especially with the sulphurets of lead; so that the lead of commerce is seldom quite free from traces of silver, and many such lead ores are worked as ores of silver.

SIMARU'BA. The bark of the root of the *Quassia simaruba*, a native of the West Indies. This is a tough, fibrous, bitter bark; the infusion is occasionally used in medicine as a tonic.

SIMARUBA'CEÆ. (Simaruba, one of the genera.) A natural order of arborescent or shrubby Exogens, inhabiting the tropics. The species are intensely bitter. The wood of quassia is well known. A plant called *Paraiba* in Brazil, the *Simaruba versicolor* of St. Hilaire, possesses such excessive bitterness that no insects will attack it; and *Picræna excelsa* is another species of the order, which is employed in medicine for the same property.

SI'MIA. (Lat. simus, *flat-nosed.*) The generic name applied by Linnæus to all the Quadrumanous Mammals, except the lemurs. The Linnæan *Simiæ* are divided into numerous subgenera, to none of which the name *Simia* is now applied, except by some modern naturalists to the orangutans (*Simia satyrus*), and *S. moris*.

SI'MILAR. (Lat. similis, *like.*) In Geometry, similar rectilineal figures are such as have their several angles respectively equal, each to each, and their sides about the equal angles proportional. The areas of two similar figures are to each other as the squares of their homologous sides. *Similar segments of circles* are such as contain equal angles. *Similar curves* are curves whose equations are of the same form, and the ratio of the constants in those equations equal. Hence all circles are similar, and all parabolas are similar; because, in both cases, only one constant enters into the equation of the curve. *Similar solids* are such as are contained by the same number of similar planes, similarly situated, and having like inclinations to one another. Such solids are to one another as the cubes of their homologous sides.

SI'MILE. (Lat. *like.*) In Rhetoric, the same as *comparison*, which see.

SIMI'LITER. (Lat. *in like manner.*) In Law, the technical designation of the form by which either party, in pleading, accepts the issue tendered by his opponent. The one having concluded his plea, replication, &c., by tendering issue in the common form, by "putting himself upon the country," *i. e.* praying that the truth of the facts may be inquired of by a jury, the other adds the similiter, which is in the form,—"And the said A. B. as to the plea, &c. of the defendant (or plaintiff) above pleaded, and whereof he hath put himself upon the country, doth the like." *See* PLEADING.

SIMI'LITUDE, in Geometry, signifies the relation of figures similar to each other.

SIMONIANS. The name given to the followers of Simon Magus, who pretended to be the great virtue and power of God sent from heaven to earth. Their system was a medley of the philosophy of Plato, the mythological fables of the heathens, and of Christianity. The sum of their doctrines, as enjoined by their founder, was, that from the Divine Being, as a fountain of light, flow various orders of eternal natures, subsisting within the plenitude of the Divine essence; that beyond these in the order of emanation are different classes of intelligences, to the lowest of which belongs the human soul; that matter is the most remote production of the emanative power, which, on account of its infinite distance from the fountain of light, possesses sluggish and malignant qualities, which appear the divine operations, and are the cause of evil; that it is the great design of philosophy to deliver the soul from its imprisonment in matter, and restore it to that divine light from which it was derived; and that for this purpose God had sent us one of the first *æons* into the world. He believed also in the transmigration of souls, and denied the resurrection of the body. (*Encyc. Brit.*) We have specified at greater length the opinions of this sect than they seem properly entitled to; but considering that it was the first heresy in the Christian church, a resumé of its views was considered not to be out of place.

SIMONIANS, SAINT. *See* SAINT SIMONIANS.

SI'MONY. In Law, an unlawful contract for the presenting a clergyman to a benefice. When such presentation is made corruptly, for money, gift, or reward, by stat. 31 Eliz. c. 6. such presentations are void, and the crown shall present for that turn. And by 12 Ann. 8. t. 2. c. 12. if any one, for money or profit, procures in his own name the next presentation to any living ecclesiastical, and is presented thereupon, the contract is simoniacal. The term is derived from Simon Magus, who was punished, as is related in the Acts, for attempting to obtain the gifts of the Holy Spirit by bribing the apostles. It is generally remarked, however, that the practices against which our laws are directed bear no precise similarity to this.

SIMOON, or SIMOOM. A hot arid wind which blows in Arabia, Syria, and the adjacent countries, and chiefly about the time of the equinoxes. The simoon, which is identical with the *khamsin* of Syria and the *samiel* of the Turks, and resembles in many respects the *sirocco* and *sorana* of other countries, derives its qualities from blowing over sandy deserts heated intensely by the sun. Sometimes it blows in squalls, bearing along with it quantities of burning sand and dust. In the desert it is greatly dreaded; and the only chance of safesty the traveller has is to fall down with his face close to the ground, and to continue as long as possible without drawing breath. It is described by Bruce, Volney, Charind, Malcolm, and other travellers.

SIMPLI'CIMANES, *Simplicimani.* (Lat. simplex, *simple;* manus, *a hand.*) A name given by Latreille to a tribe of Caraboid beetles, comprehending those in which, in the male, the two anterior tarsi are dilated.

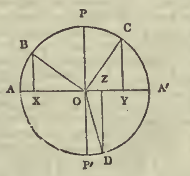
SIMPLI'CITY. (From Lat. simplex.) In the Fine Arts, that quality in works of art through which the elements whereof it is composed are arranged in the most natural order; and in which the ideas and images are presented to us so that the principal objects are not eclipsed by the accessories, and the details are in due subordination to the whole. Simplicity is the reverse of excess and exaggeration, and may be properly called a negative quality in art.

SI'NAPISIN. A peculiar principle extracted from mustard seed (*Sinapis alba*). It is a white crystallizable inodorous substance, of a bitter taste, accompanied by the flavour of mustard. It is supposed to contain sulphur, carbon, nitrogen, hydrogen, and oxygen.

SI'NAPISM. (Lat. sinape, *mustard.*) A mustard poultice.

SI'NCIPUT. The anterior region of the upper part of the head, from the vertex to the eyes in Mammals, and from the vertex to the base of the beak in birds.

SINE. (Lat. sinus, *the bosom.*) In Trigonometry, the sine of any arc of a circle is the straight line drawn from one extremity of the arc perpendicular to the radius passing through the other extremity. Thus, in the circle A B C D, let O A and O B be two radii, and let B X be perpendicular to O A; then B X is the sine of the intercepted arc A B. In like manner, if C Y and D Z be perpendicular to A O, or its prolongation O A′; then C Y is the sine of the arc A B C, or of A′ C, the supplement of A B C, and D Z the sine of A C D, or of A′ D.



Draw the diameter P O P′, and suppose the arc A B to increase from 0 to 360°. It is evident that as the arc A B increases from A to A P, or from 0 to 90°, the sine B X increases from zero to O P, where it becomes equal to the radius; and hence the radius is called the *sinus totus*, or whole sine. Between P and A the sine again diminishes as the arc is increased, and vanishes at A′. From A towards P′ it again increases till it becomes equal to the radius O P′, and from this position decreases until it again vanishes at A. Hence it appears that the origin being supposed at A, the sine is positive in the first and second quadrants, or from 0 to 180°; and negative in the third and fourth, or from 180° to 360°.

If we conceive another circle to be described about the same centre O, the two lines O A and O B would intercept on it an arc similar to A B; and if, also, we suppose the radius of this second circle = 1, and denote the inter-

cepted arc by ϕ; then we shall have evidently sin. ϕ : 1 : : B X : B O, or sin. $\phi = \frac{BX}{BO}$. But the arc whose radius is 1 is the measure of the angle at the centre; therefore the sine of the angle A O B is the ratio of B X to B O, or A O. This definition of the sine of an angle is adopted in some of the best recent works on trigonometry.

The sine of an arc is the half of the chord of the double arc. Ptolemy, in the graphical constructions in the *Analemma*, makes use of the semichords instead of the chords; but the introduction of the sines into trigonometrical calculation was an important improvement, of which the credit appears to be due to the Arabian astronomer Albategnius. (Delambre, *Astronomie du Moyen Age*, p. 12.) The term *sine* has been variously derived; the Arabic name is *gib*, or *dgib*, signifying *a fold*, of which *sinus* is the Latin translation. (*Hutton's Mathematical Tables*.)

For the analytical expressions of the sines of the sums and differences of two arcs, of multiple arcs, and of the other trigonometrical lines, see TRIGONOMETRY.

SI'NECURE. In Politics, an office without any duties attached to it. The term is properly ecclesiastical, and applied to a benefice without care of souls; in which sense it is also still employed.

SINE DIE. (Lat. *without day.*) In Legal and Parliamentary Usage, an adjournment or prorogation *sine die* means without any specified day for resuming the subject, or reassembling.

SI'NGULAR TERM. In Logic, a term which stands for one individual. A singular proposition is one which has for its subject either a singular term, or a common term limited to one individual by a singular sign. *See* TERM, PROPOSITION.

SINI'STER (Lat. literally *left*), is used in its ordinary signification for unlucky; though the Romans in the rites of divination attached to it the opposite meaning. Thus *avis sinistra*, or a bird on the left hand, was esteemed a happy omen; and *intonuit lævâ*, it thundered, on the left hand, indicated the same. *Sinister*, in Heraldry, is used to designate the left-hand side or part.

SINKING FUND. A provision made by parliament, consisting of the surplusage of other funds, intended to be appropriated to the payment of the national debt. *See* FUNDS.

SINO'PLE. In Heraldry, the Continental designation for the colour green; by English heralds called *vert*. The name is said to be derived, through the importation of the Crusades, from the town of Sinope, in Asia Minor.

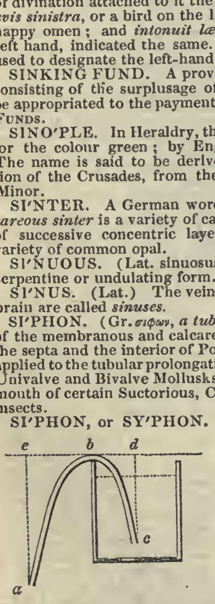
SI'NTER. A German word implying a *scale*. *Calcareous sinter* is a variety of carbonate of lime composed of successive concentric layers. *Silicious sinter* is a variety of common opal.

SI'NUOUS. (Lat. sinuosus.) In the Fine Arts, of a serpentine or undulating form.

SI'NUS. (Lat.) The veins of the dura mater of the brain are called *sinuses*.

SI'PHON. (Gr. σιφων, *a tube.*) In Zoology, the name of the membranous and calcareous tubes which traverse the septa and the interior of Polythalamous shells. Also applied to the tubular prolongation of the mantle in certain Univalve and Bivalve Mollusks; and by Latreille to the mouth of certain Suctorious, Crustaceous, and Apterous insects.

SI'PHON, or SY'PHON. In Hydraulics, a simple and well-known instrument, chiefly used for the purpose of drawing off liquids from casks. The siphon is simply a bent tube, *a b c*, having one end longer than the other. To use the siphon, the tube is in the first place filled with the liquid, and the open end *a* stopt by the hand, or by a cock, in which state the liquid will not flow from the other extremity. The end *c* is then immersed in the liquid, and the stop removed from *a*; upon which, if *a* be at a lower level than *c*, the liquid will immediately begin to flow out at *a*, and will continue to flow until the vessel is drained down to the level of *c*.



The principle of the siphon may be explained as follows: — The lowest section of the fluid within the tube at the extremity *c* is subjected to two unequal pressures in opposite directions: first, the pressure due to the weight of the liquid in the branch *b c*, which pressure is equal to the line *c d*, perpendicular to the horizontal line drawn through the highest part of the tube, and tends to force the liquid out of the tube; secondly, the pressure of the external liquor at *c*, which is equal to the atmospheric pressure, or the weight of a column of liquid of about 34 feet in height, together with the weight of the column reaching from *c* to the surface of the liquid in the vessel, which, however, we may leave out of consideration. Hence, if the line *c d* be less than 34 feet (if the liquid be water), the last pressure will preponderate, and the liquid will be forced into the tube by a pressure equal to the weight of the atmosphere diminished by the weight of a column of the fluid equal to *c d*. In like manner, the pressure upon a section of the liquid at *a* is equal to the weight of the atmospheric column diminished by the weight of a column of the fluid equal in height to *a e*. If, therefore, *a e* be greater than *c d*, the pressure at *c* will be greater than the pressure at *a*, and the liquid will be forced through the tube.

From this explanation it is obvious that the limits within which the siphon can act are determined by the specific gravity of the fluid. Water cannot be raised by the siphon to a greater height than 34 feet, nor mercury to a greater height than 30 inches. It is also obvious that the comparative diameters of the two branches, and their oblique lengths, are of no importance, the action depending only on the difference of their perpendicular heights.

Sometimes the siphon is made with both branches equal, and turned up at the extremities; in which case, so long as the extremities are kept on the same level, it will continue always full and ready for use. This form of the instrument is called the *Wurtemberg siphon*, from its having been first used at that place.

SIPHONA'PTERANS, *Siphonaptera*. (Gr. σιφων, α priv., and πτερον, *a wing.*) A name given by Latreille to an order of insects, including those Apterous species which have a mouth in the form of a siphon.

SIPHO'NIFERS, *Siphonifera*. (Gr. σιφων; Lat. fero, *I bear.*) A name given by D'Orbigny and Ferussac to an order of Cephalopods, including all those species which have a siphon contained within a polythalamous shell.

SIPHONOBRAN'CHIATES, *Siphonobranchiata*. (Gr. σιφων, and βραγχια, *gills.*) The name of an order of Gastropods, including those in which the branchial cavity terminates in a tube or siphon more or less prolonged, by which the respiratory current of water is received and expelled.

SIPHO'NOPHORES, *Siphonophora*. (Gr. σιφων, and φερω, *I bear.*) A name given by Escholtz to an order of Acalephes, to which he refers those species that have no central digestive cavity, but simply isolated tubes.

SIPHO'NOSTOMES, *Siphonostoma*. (Gr. σιφων, and στομα, *a mouth.*) The name of a family of Crustaceans, comprehending those which have a siphon-shaped mouth for suction. By M. de Blainville the term is applied to those Gastropods which have the opening of the shell prolonged into a siphon.

SIPHORHI'NIANS, *Siphorhinii*. (Gr. σιφων, and ῥιν, *a nose.*) A name applied to a tribe of swimming birds, including those which have the nostrils prominent and tubular.

SIP'UNCLE, *Sipunculus*. The name of a genus of worms which burrow in the sands of the sea-shore, and are classed with the *Echinoderms* by Cuvier, and with the *Entozoa* by M. de Blainville. They differ from the soft-bodied *Echinoderms* chiefly in the absence of ambulacral pores.

SIR. The term used in England, either out of respect or formality, in addressing any one. More particularly, it is the distinguishing appellation of knights and baronets, to whose Christian names it is prefixed. The derivation of this word has greatly puzzled etymologists. The Lat. herus, *master* (whence the Germ. herr), and senior, whence *signor*, *siore*, *sire*, *sir*, and the Gr. κυριος, *lord*, are specimens of the origin which has been assigned to this term. The second is undoubtedly correct. Since the 16th century, the word *sire* has been used in prose only in addressing sovereign princes.

SI'REN. The generic name of certain Perennibranchiate reptiles which have only one pair of feet, and retain the external gills; they are peculiar to the southern provinces of the United States.

SIRE'NE. In Acoustics, an instrument for determining the velocity of aërial vibration, corresponding to the different pitches of musical sounds. "In this elegant instrument the wind of a bellows is emitted through a small aperture, before which revolves a circular disc pierced with a certain number of holes, arranged in a circle concentric with the axis of rotation, exactly equidistant from each other, and of the same size, &c. The orifice through which the air passes is so situated that each of these holes, during the rotation of the disc, shall pass over it, and let through the air; but the disc is made to revolve so near the orifice that in the intervals between the holes it shall act as a cover, and intercept the air. If the holes be placed obliquely, the action of the current of air alone will set the disc in motion; if perpendicular to the surface, the disc must be moved by wheel-work, by means of which its velocity of rotation is easily regulated, and the number of impulses may be exactly counted. The sound produced is clear and sweet, like the human voice. If, instead of a single aper-

ture for transmitting the air, there be several, so disposed in a circle of equal dimensions with that in which the holes of the disc are situated that each shall be opposite one corresponding hole when at rest, these will all form sounds of one pitch, and being heard together will reinforce each other. The sirene sounds equally when plunged in water and fed by a current of that fluid as in air; thus proving that it is the number of impulses only, and nothing depending on the nature of the medium in which the sound is excited, that influences our appreciation of its pitch." (Sir John Herschel's Treatise on Sound, *Encyc. Metropolitana.*)

The sirene, as thus described, was invented by Baron Cagniard de la Tour. An instrument on the same principle, and for the same purpose, had formerly been devised by Professor Robison; but the construction was much less elegant and commodious. A current of air passing through a pipe was alternately intercepted and permitted to pass by the shutting and opening of a stop cock.

SI'RENS. (Gr. Σειρῆνες; probably from σειρα, *a chain*, to signify their attractive power.) Melodious divinities, who dwelt on the shores of Sicily, and so charmed passing mariners by the sweetness of their song that they forgot their homes, and remained there till they perished of hunger. Their history has been variously described. According to Homer, in the *Odyssey*, as Ulysses and his companions were on their homeward voyage from Æaca, they came first to the island of the Sirens: but they passed in safety; for, by the directions of Circe, Ulysses stopped the ears of his companions with wax, and had himself tied to the mast before approaching the island; so that, although when he heard the song of the Sirens he made signs for his companions to unbind him, they only secured him the more closely in compliance with his previous instructions. Thus he listened to the songs of the Sirens, and escaped notwithstanding. Hence it was feigned that they threw themselves into the sea from vexation at the escape of Ulysses, an oracle having predicted that they should live only so long as their strains had power to arrest all who heard them. But according to other poets, they threw themselves into the sea from rage and despair on hearing the more melodious song of Orpheus. Originally there were only two Sirens; but their number was afterwards increased to three, and their names are given with great variety. See the speculations of Bryant on the subject, *Anc. Mythol.* ii. 277., and iii. 237.

SI'RIUS (called also *Canicula*, or *Canis Candens*, the *Dog-star*). A star of the first magnitude in the constellation of *Canis Major*, or the Great Dog, and the brightest in the heavens. The Egyptians observing that the Nile begins to swell at a particular rising of this star, paid it divine honours, and named it *Sirius;* from *Siris*, one of the appellations of the Nile.

SIRO'CCO. (Ital.) A soft relaxing wind, chiefly experienced in the south of Italy, Malta, and Sicily. It blows from the south-east or south; and having been heated over the sandy deserts of Libyia, it becomes occasionally moist in its passage across the Mediterranean, and oppresses the inhabitants of the above-named countries with excessive languor, and a sinking of the mental energies. The setting in of the sirocco is followed by a considerable rise of the thermometer, and is attended with a haze which obscures the atmosphere. *See* SIMOON.

SIRVE'NTE. In the Literature of the Middle Ages, a species of poem in common use among the Troubadours, usually satirical, and divided into strophes of a peculiar construction. *See* TROUBADOUR.

SI'STRUM. (Gr. σεῖστρον; from σείειν, *to shake.*) A kind of timbrel, which the Egyptian priests of Isis used to shake with their hands at the festivals of that goddess.

SI'SYPHUS. In Ancient Mythology, one of the descendants of Æolus, respecting whom a variety of opinions prevails. By some he is said to have resided at Epyra in the Peloponnesus; others maintain that he was a Trojan prince, who was punished for betraying state secrets; while others allege that he was a notorious robber, slain by Theseus. Be this as it may, all the ancient poets are agreed that he was distinguished for his craftiness and cunning; and that his punishment in Tartarus for his crimes committed on earth consisted in rolling a huge stone to the top of a high hill, which constantly recoiled, and thus rendered his labour incessant. The term Sisyphus is supposed to be derived from Gr. σισοφος (by a common duplication for σοφος, *wise*), and to signify *overwise.*

SI'TTA. (Gr. σιττα.) The name of a bird in Aristotle, which Gesner determined to be the nuthatch. Linnæus retains the term for the genus of which the nuthatch (*Sitta Europæa*, L.) is the type.

SIVA. In Hindoo Mythology, a title given to the Supreme Being, considered in the character of the avenger or destroyer. Sir William Jones has compared Siva to Jupiter; but he appears to share many of the attributes of Pluto. Under the name of Mahadeva, he is exhibited also as a type of reproduction: to destroy, according to the Vedantas of India, the Sufis of Persia, and even to many European schools of philosophy, being only to generate or reproduce under another form. *See* VISHNU, BRAMA.

SIVATHE'RIUM. (Siva; and Gr. θηριον, *a wild beast.*) The name of an extinct genus of Ruminantia found in fossil remains in the tertiary strata of the Sivalik Sub-Himalayan range. It surpassed all known ruminants in size, and had four horns.

SI'ZARS. The lowest class of students at Cambridge. At Oxford the same class go in different colleges by the denominations of servitors, &c. They are such as have certain allowances made in their battels (college bills), through the benefactions of founders or other charitable persons. In college phraseology, a size is a portion of bread, meat, &c. allotted to a student; and hence the name sizar. The sizars at Cambridge are almost entirely on the same footing with independent students; at Oxford they are somewhat lower, and some relics of their former degraded condition still subsist in certain colleges in the customs of bringing up dishes to dinner, dining off the remnants of the fellows' dinners, &c.

SIZE. A sort of varnish, paint, or glue, used by painters, and in many other trades. It is made of the shreds and parings of leather, parchment, or vellum, boiled in water and strained.

SKE'LETON. (Gr. σκελλω, *I make dry.*) The desiccated support or framework of an animal body, which, usually consisting of different parts, may be joined together by the dried natural ligaments, when it is termed "a natural skeleton;" or may be articulated artificially, when it is termed "an artificial skeleton." In the lowest-organized animals, as the *Polygastria* and *Polypi*, the skeleton, when it exists, commonly consists of a single piece. In the *Polygastria* it is external, in the form of a case, and consists of pure silex. In the *Polypi* it is sometimes external, sometimes internal; and is composed of either pure carbonate of lime, or with a small additional proportion of phosphate of lime, and these earths are combined with a greater or less proportion of gelatinous animal matter. In the *Isis* the skeleton consists of numerous separate calcareous joints, connected together by portions of uncalcified gelatin. In many of the Lithophytous *Polypes* innumerable minute spiculæ, of various but definite forms, are scattered through the fleshy investment of the main internal skeleton. In the *Echinoderms* the skeleton is external, as regards the viscera; but is covered by an organized skin. It is chiefly remarkable for the great number of pieces of which it is composed, and the regular and beautiful forms in which they are combined; it likewise supports numerous tubercles or spines: it is composed of carbonate and phosphate of lime, with a gelatinous basis. In *Insects* the skeleton is partly internal, but chiefly external; and its hardening material is a peculiar animal principle, called "chitine." In cabinets of dried insects it is the natural skeleton that is preserved. In *Crustacea* the skeleton, which bears the same relative position to the animal as in insects, is rendered denser and more brittle by being consolidated with the carbonate and phosphate of lime. In the *Mollusca* the skeleton is generally external, but sometimes internal; it is hardened by the carbonate of lime, with a very slight trace of the phosphate of lime, and constitutes the shell. The beauty, durability, and variety of form of this modification of the skeleton, have rendered the shells of the *Mollusca* at all times a favourite object of collectors, and the subject of a distinct branch of natural history, under the name of "Conchology." The skeleton of mollusks is either in one piece, as in the univalve mollusks; or in two pieces, as in most bivalves; or in many pieces, as in the multivalve chitons, and others. In the *Cephalopods*, besides the shell, which offers remarkable varieties of form and substance, there is likewise a rudiment of true internal skeleton in a cartilaginous condition. In the Vertebrate animals, there is always an internal skeleton destined to protect the central part of the nervous system, and to form the fulcrum and support of the locomotive members. In a few fishes it is cartilaginous; in the rest of the Vertebrates it is osseous, or consolidated by a large proportion of phosphate and a small proportion of carbonate of lime, and some other hardening salts. (*See* BONE.) This is termed the "endo-skeleton." In most fishes, in several reptiles, as the crocodilians, and in the armadillos amongst the Mammalia, osseous plates are developed in the substance of the skin; these are analogous to the skeleton of most of the Invertebrate animals, and form a more or less complete protecting case, called the "exo-skeleton."

SKETCH. (It. schizzo.) In Painting, &c., the first delineated idea of the artist's conception of a subject, in which are usually distinguishable the fire and enthusiasm with which the subject is expressed and felt.

SKEW BACK. In Architecture, the sloping abutment, in brickwork and masonry, for the ends of the arched head of an aperture.

SKEW BRIDGE. In Engineering, the name given to a kind of bridge introduced upon railroads, when the

railway intersects any existing communication at right angles. Such bridges were occasionally built before railroads were introduced; but their general introduction has rendered the use of skew bridges universal in cases where it may be necessary or unavoidable to preserve as straight or direct a line as possible. The *Ency. Britannica* contains an elaborate article upon this subject.

SKIN. The external covering of the body. It is divisible into three parts or membranes. The exterior is called the scarfskin or cuticle: it is an albuminous membrane. Immediately underneath it is a thin layer of soft or pulpy matter, called the *rete mucosum* (mucous network), which is the seat of colour: it lies upon the *cutis*, or true skin, which is a gelatinous texture.

SKIP. (Fr. esquiver.) In Music, a passage from one sound to another by more than a degree at one time.

SKI'RTING. In Architecture, the narrow vertical board on the floor round the sides of an apartment.

SKO'LEZITE. (Gr. σκολος, *twisted.*) A mineral which occurs crystallized and massive. It is colourless and translucent, and when heated before the blowpipe shrinks up into wormlike contortions.

SKO'RODITE. (Gr. σκοροδον, *garlic;* in allusion to its odour when heated.) An arseniate of iron.

SKO'RZITE. A mineralogical synonym of a variety of epidote, from Skorza.

SKULL. The bony case which contains the brain: it forms the forehead, and every part of the head except the face. It consists of eight bones; namely, the frontal and occipital bones, upon its fore and back part; the two temporal and two parietal bones, forming the temples and the sides of the skull; and the sphenoid and ethmoid bones, concerned in the formation of the orbits and nose.

SKY LARK. The name of a species of the genus *Alauda* (see that word); the *Alauda arvensis* of Linnæus.

SKY SAIL. A small sail sometimes set above the royal.

SLAB LINE. A small rope leading through a block under the lower yards, and thence to the foot of the sail, for the purpose of *tricing* it up.

SLACK. Small coal under the size of an egg.

SLAG. The imperfect glassy or vitrifiable compounds which are produced during the reduction of metallic ores by various fluxes. In the neighbourhood of large smelting works, especially of iron and copper, the slags, which are abundantly produced, are sometimes used as building materials, and for making and mending roads. They often contain a considerable relative proportion of metal.

SLA'NDER. In Law, a malicious defamation of a man by words spoken. It is not actionable unless it impute some crime punishable by law; or some infectious disease, such as leprosy or the like, which may have the effect of excluding from society the person slandered; or be uttered concerning him in his trade or business in such a way as to impair his means of livelihood; or, lastly, unless it be attended with special damage. In this case, such special damage must be averred upon the pleadings. If special damage be not proved by the plaintiff, he will not, in any action for words spoken, when the verdict is under 40 shillings, be allowed more costs than damages. A defendant cannot be proceeded against criminally for words spoken, unless they have a direct tendency to a breach of the peace, as by containing a challenge to fight; or are of a seditious or grossly immoral character; or are spoken of a magistrate in the execution of his duty.

SLATE. *See* GEOLOGY.

SLA'VERY, properly so called, is the establishment of a right, which gives to one man such a power over another as makes him absolute master of his life and property. But the condition of a slave is susceptible of innumerable modifications; and there are few nations, whether of ancient or modern times, among whom slavery has been long established, that have not enacted certain laws for limiting the power of a master over his slave. Slavery has existed from the earliest periods of authenticated history, and its origin has generally been ascribed to a state of war. In the rudest stages of society, the difficulty of subsistence was so great that the lives of captives were seldom spared; but as society advanced, and luxuries began to be introduced, the aid of labourers became requisite, and it was found more profitable to employ than to slay a captive. Thus the Latin word servus, *a slave*, appears to have been derived from servo, *I preserve*, and to have meant a person whose life was preserved on condition of giving his labour to his conqueror; so that a state of slavery, how repulsive soever to our present feelings, probably formed at one time an important mitigation of the horrors of barbarism. But in proportion as society rose in the scale of civilization, the state of slavery sprung from a variety of causes. Thus, in several countries, those who had been convicted of crimes were often doomed to perpetual slavery; and as a necessary corollary of this principle of slavery, it was laid down as a fundamental regulation, that slaves could only beget slaves; and hence the principle of hereditary bondage. It would be foreign to the purpose of this work to enter into details upon the different phases which slavery has exhibited in the various countries in which it has existed, or to point out the malignant influence it has exercised upon the character of every nation among whom it has been tolerated. Upon this subject the reader will find ample details in the third volume of the *Cours d'Economie Politique* of M. Storch, Paris, 1823; and with regard to slavery as practised among the Romans, he may consult with advantage the elaborate little volume of Mr. Blair on this subject. The species of slavery which existed during the feudal ages, and which is still to be found in some European countries, will be found noticed under the heads SERF, SERVITUDE, and VILLEIN, in this work; and for some details of negro slavery, see *infra*, and NEGROES.

The British legislature, as is well known, passed an act in 1834 for the emancipation of Negro slaves throughout our dominions; by which, after passing through a preliminary term of compulsory apprenticeship, they were eventually raised to the condition of full citizenship.

SLAVE TRADE, generally denotes the trade in slaves carried on by European nations between the western coasts of Africa and the American settlements; abolished, as far as Great Britain is concerned, in 1808.

The European slave trade is, however, generally supposed to have been commenced by the Portuguese about the end of the 15th century. About 1508 the Spaniards began to import Negroes into America, to supply the place of the Indians, whose numbers were rapidly diminishing under the severity of the toil to which they were exposed by their conquerors. Sir John Hawkins, one of Queen Elizabeth's most famous captains, seems to have been the first Englishman of note who embarked in this traffic, having been concerned in the sale of Negroes to the Spaniards in the West Indies. In the same reign the African Company was first chartered, for the purpose of trade with Guinea. This company carried on a trade in Negroes with the English settlements in America from the beginning of the 17th century to the year 1732, when that traffic was abandoned by it, and chiefly carried on from that time by private traders. It was not until the latter end of the 18th century that the atrocities of this trade began to engage the attention of parliament. In 1788 an act was passed to regulate it; and after twenty years' animated discussion, it was at last totally abolished in 1807. The United States of America and Denmark had preceded us in this righteous act. (See *Clarkson's History of the Abolition of the Slave Trade.*)

The slave trade is now prohibited by the laws of most European nations, except Portugal; and by the law of that country it can only be carried on within certain geographical limits. Nevertheless it is extensively carried on by contraband dealers; and no measure can be reasonably expected to put a stop to it short of its being declared* piracy by the common consent of civilized states. To obtain this result ought to be one of the most prominent objects of English diplomacy, both for the sake of humanity, and in order to protect the interests of our own colonies, which suffer severely from competition with those European possessions into which an unlimited importation of slave labour takes place. But it must be admitted that Sir Fowell Buxton, whose name ranks so high among the opponents of the slave trade, appears to confess that even this measure would prove ineffectual, from the difficulty of execution. We can do no more here than advert to the scheme recently proposed, received with acclamation by a great portion of the public, and taken up by government, of establishing a legitimate trade with central Africa by the channel of the Niger. We can only say that those who expected the slightest effect to be produced on the progress of this abominable traffic by any such measure, must have estimated both end and means in a very different manner from ourselves; but the official report of Captain Trotter has recently announced the utter failure of the expedition, owing to the destructive influence of the climate; and the general opinion seems to be, that henceforth those who may induce their fellow-countrymen to embark in any similar adventure will involve themselves in very serious responsibility. According to some recent estimates, about 75,000 slaves are supposed to be annually carried from their homes in Africa to supply the American markets, including those who perish by the way. There can, however, be no doubt that this estimate is very greatly exaggerated; and we question whether, taking those exported from the east coast to Arabia, &c. into account, the average number of slaves carried from Africa during the seven years ending with 1841 can have been as high as 40,000 a year; and now, no doubt, even this exportation will be very materially reduced. The principal import-

* This most desirable act has been recently accomplished; the whole of the European states having agreed to enforce the strictest measures in regard to the *right of search*, and to regard those engaged in the trade as pirates. From this humane declaration the United States have hitherto withheld their assent.

ing countries are Cuba, Portorico, and Brazil. Publications on the slave trade are so numerous, that it is difficult to make a selection for purposes of reference. Perhaps (after *Clarkson's History*) the student could not find the account of its progress better given than in successive numbers of the *Edin. Review*, especially vols. xxi. xxiii. xxiv. xxxvi.; though it must be admitted that there is in these, and most works on the subject, a strong tendency to exaggeration. There is a good article on the international law of the slave trade in the *Law Magazine* for August, 1841.

SLEEP. (Germ. schlaf.) That state of the body in which the functions of sensation and volition are suspended, while the vital functions retain their usual activity: the operations of the mind, if not at perfect rest, are disconnected with external objects.

Healthy or natural sleep usually comes on with a peculiar sense of muscular lassitude, gaping, and desire of repose; the eyelids fall, and there is general muscular relaxation. The sense of hearing is that which is longest retained; and we generally hear what is going on about us, and even feel inclined to take occasional part in conversation, long after the eyes are closed.

The quantity of sleep required by different individuals is various, from six to nine hours being the average proportion. Indolent listless persons, and especially those who indulge in the luxuries of the table, and are in good health, will often slumber away from eight to ten hours daily; while others of active dispositions, and who live abstemiously, will be satisfied with four or five hours of sleep: and such persons are generally more disturbed by dreams than the former. Very young children sleep away much of their time, and so also do many old persons. Sleep is often prevented by intense thought, by anxiety, and other mental affections; and also by hunger, and by the application of cold to a part of the body. When a person has been over-fatigued by bodily exertion, sleep is also often courted in vain; and there are many stimuli by which its accession at the usual times is prevented or retarded, such as strong tea, coffee, small doses of opium, and several other articles of medicine and diet. Bodily exercise and mental tranquillity, a full meal, the absence of light, noise, and other disturbing causes, are circumstances generally favourable to sleep; but in all these respects various habits often greatly interfere, and persons accustomed to very active lives when suddenly deprived of their usual occupations often sleep worse than before, indolence becoming an apparent stimulant. A distended stomach keeps some individuals awake; and others cannot sleep in a dark room, or in the quiet of the country, who have been used to a night lamp, and to the rumbling of carriages over a London pavement.

The proximate cause of sleep has been discussed by several eminent physiologists, but without any very satisfactory results: it is, in fact, as entirely beyond our grasp, as are the other functions of the nervous system. *See* DREAMS.

SLEEPER. In Architecture, a piece of timber whereon are laid the ground joists of a floor. *Sleepers* are also pieces of timber, now rarely used, in foundations crossed by planks, &c., and at right angles to them, where the soil is bad. Formerly the term was used to denote the valley rafters of a roof.

SLI'CKENSIDE. A provincial term applied by the Derbyshire miners to a species of galena, or sulphuret of lead.

SLIDE. In Music, a grace used in the German school, and consisting of two small notes moving by degrees.

SLI'DING KEEL, is a narrow oblong frame or platform, let down vertically through the bottom of a small vessel, like a deepening of the keel throughout a portion of her length. Its use is, like that of the leeboard, to sustain the vessel against the lateral force of the wind.

SLI'DING RULE. A mathematical instrument or scale, consisting of two parts, one of which *slides* along the other, and each having certain sets of numbers engraved on it, so arranged that when a given number on the one scale is brought to coincide with a given number on the other, the product or some other function of the two numbers is obtained by inspection. The numbers may be adapted to answer various purposes; but the instrument is chiefly used in gauging, and for the mensuration of timber.

SLING. (Ger. schlinge.) A weapon made of a strap and two strings, by means of which a stone or other missile is projected with much greater velocity than could be given to it by the hand without such assistance. The velocity with which the projectile is discharged is the same as that with which it is whirled round in a circle having the string for its radius, and may therefore be computed when the time of revolution and the length of the string are given. The sling was known as a weapon of offence in the earliest ages.

SLIPS. In Geology, masses of strata separated vertically or aslant.

SLOAM. Layers of clay between those of coal.

SLOOP. A vessel with one mast like a cutter; but having a jib stay, which a cutter has not. Also the general name of ships of war below the size of frigates.

SLOPS. Clothes and bedding supplied from the ship's stores to the seamen, but at their expense.

SLOUGH. A Surgical term applied to the separation which ensues between dead and living parts.

SLUE. In Naval language, *to slue* is to turn a cylindrical piece of timber, as a mast or boom, about its axis, without moving it out of its place.

SLUICE. (Lat. clausus, *shut up*.) In Hydraulics, a frame of timber, stone, or other solid substance, serving to retain and raise the water of a river or canal, and, when necessary, to give it vent.

SLUR. In Music, an arch ⌒ connecting two or more notes not on the same degree, indicating to the performer that in playing they are to be united as much as possible.

SMACK. A vessel with one mast, commonly rigged as a sloop, and used in the coasting trade, or as a tender in the royal navy. The vessels of this name that have long plied between Leith and London are well known, and have always been noted for their security.

SMALLPOX. Called also *Variola*, from varius, *changing colour*; because it changes and disfigures the skin. There are two forms of this disease, generally called by medical men the *distinct* and the *confluent*; in the former the pustules are separate, in the latter they coalesce. *Distinct smallpox* begins with the usual symptoms of inflammatory fever; that is, pains in the back and loins, sickness, drowsiness, headach, pain upon pressure about the region of the stomach, and in infants one or more epileptic fits. About the end of the third day little red spots, much resembling flea-bites, make their appearance upon the face and head, which spread during the fourth day over the breast, body, and limbs; about the fifth day a small circular vesicle forms upon each little point, depressed in the centre, surrounded by an inflamed margin, and containing a colourless fluid, and at this time the eruptive fever disappears; about the sixth day the throat becomes sore, and the saliva viscid; and about the eighth day the face is swollen, and the pustules round, prominent, and prevalent; about the eleventh day the pustules attain their full size (about that of a pea), and the matter which they contain becomes opaque and yellow, and a dark central spot appears on each; the swelling of the face subsides, and is transferred to the hands and feet, and more or less secondary fever now ensues. After this the pustules become rough, break, and scab over, and a dark brown spot remains for some days; and if the pustules have been large an indentation is left: the remaining symptoms gradually subside, and about the seventeeth or eighteenth day the secondary fever disappears.

Confluent smallpox is ushered in by a fever of a typhoid rather than of an inflammatory character; all the incipient symptoms are aggravated; delirium or coma attends them; and in infants there is diarrhœa, and in adults salivation. The eruption is very irregular in its progress and appearance, and usually preceded by red patches upon the face, from which the pustules emerge on the second day in the form of clusters somewhat resembling measles. Their progress is rapid; but instead of being circular and well-defined, they are flat and irregular in shape, and contain a brownish fluid very unlike pus: the intermediate spaces between the clusters are generally pale and flaccid. The tumefaction of the face and running of saliva are greater than in the distinct species; and the fever does not cease upon the appearance of the eruption, but about the ninth day it generally becomes aggravated, the eruption livid, and accompanied by petechiæ or purple spots; and about the eleventh day from the commencement of the disease it often terminates fatally.

This disease is the effect of a specific contagion, and is produced either by inoculation, or by exposure to the effluvia from persons suffering under it: in the latter case it is usually called the *natural smallpox*. When the distinct smallpox goes regularly through the stages above described it is rarely dangerous, except from mismanagement; but it often leaves a tendency to inflammatory disorders, and in a scrofulous habit it excites that disorder into activity. Any of the symptoms which have just been described as characterizing confluent smallpox are alarming; so is a sudden disappearance of the eruption, or change in its appearance, followed by depression or delirium. In treating the distinct smallpox the febrile symptoms are to be moderated by cool air, saline and mild acid and diluting drinks, and very gentle aperients. Bleeding and purging are in almost all cases to be decidedly avoided. Great irritability may occasionally be allayed by small doses of opium and camphor, or, which is preferable, by muriate of morphia: this will also check diarrhœa, should it supervene. The confluent form generally requires more or less of the treatment which is adopted in low or putrid fever. Obstinate vomiting, which is sometimes not only a troublesome but alarming symptom, is best encountered by the saline draught in the act of effervescence, with a few grains of aromatic confection, and a few drops of tincture of opium.

SMALT. (Germ. schmalz.) A fine blue colour used

in painting and printing upon earthenware, and applied to several other purposes in the arts. The finest smalt is made by fusing glass with oxide of cobalt, by which a very deep blue compound is obtained, which when finely powdered acquires a beautiful azure colour. Common smalts are prepared by fusing mixtures of zaffre, sand, and pearlash.

SMARAGD. (Gr. σμαραγδος.) In modern times used as a synonym of emerald (which see); but applied by the ancients to various other precious stones, such as fluor spar, green vitrified lava, green jasper, and green glass. The passage of Pliny (*Nat. Hist.* xxxvii. 5.) in which Nero is said to have been in the habit of viewing the gladiatorial combats *in a smaragd*, is generally understood to signify a smooth polished mirror made of some of the above substances; but it has been maintained that the emperor was short-sighted, and used a concave eyeglass formed of the smaragd. The smaragd is found in various parts of Europe, Asia, and America; but particularly in the Ural mountains, and in the mines of Chili and Mexico.

SMART TICKET. A certificate of a seaman's having received a wound or hurt.

SMELL. This sense resides in the mucous or pituitary membrane which lines the nostrils, and the surface of which is more or less convoluted or extended in various orders of animals. In the human subject this membrane is highly vascular, and largely supplied, especially in its upper parts, with nervous filaments, or ramifications of the olfactory trunk, which has its origin, by three distinct roots, from the posterior, inferior, and internal parts of the anterior lobe of the brain, and proceeding towards the perforated plate of the ethmoid bone, divides into the small threads just mentioned.

The physiology of odours is a curious and intricate subject, requiring much more experimental investigation than it has hitherto received. The air is the great vehicle by which their various influences are transmitted in the act of inspiring to the olfactory surfaces, and for the diffusion of most odours a certain degree of humidity in the air appears absolutely essential. There is scarcely any sense the degree of perfection of which varies so much in different individuals as that of smell, some being painfully alive to those odorous influences which are not even perceived by others. An obtuseness of this sense is also very frequent, and its almost entire absence by no means uncommon; this is especially the case in certain catarrhal complaints, and in some other affections of the lining membrane of the nose.

SMEW. The name of the diver called *Mergus albellus* by Linnæus. *See* MERGUS.

SMILA'CEÆ (Smilax, one of the genera), form a small natural order of Endogenous plants with weak or twining stems and reticulated leaves, not distinguishable from those of Exogens. The drug called sarsparilla, or sarza, is the root of various species inhabiting South America, and is held in high esteem for its diuretic, demulcent, alterative qualities.

SMOKE. (Low Germ. smuke.) Smoke has been defined as the visible effluvium or sensible exhalation of any thing burning. The term is commonly applied to those results of the combustion or ignition of pit coal which escape from chimneys, and which constitute a serious and well-known evil and nuisance in large towns, manufacturing districts, and almost every where where large quantities of coal are consumed. Coal is often a very complex substance; but, putting aside its occasional and adventitious ingredients, carbon, hydrogen, nitrogen, and oxygen may be regarded as its ordinary and essential constituents; and the results of its *perfect* combustion would therefore be carbonic acid steam and nitrogen. These substances would constitute invisible and incombustible gases and vapour, and would therefore escape from the chimney top, and blend with the atmosphere, without being perceived. But it unfortunately happens that from the way in which coal is burned its combustion is far from being perfect, and that besides the above-mentioned products inflammable gases and vapours, together with large quantities of very finely divided carbon, constituting soot and black and brown smoke, are vomited forth from the chimney shaft, not only contaminating the air, and making all neighbouring objects black and dirty, but also occasioning great loss of fuel; so that the smoke of London is not only a nuisance, but a very expensive one, and ought to be put down by legislative enactments, several of which have been from time to time suggested, but unfortunately never enforced, and are at this moment a mere dead letter.

The neglect which this subject has encountered has arisen chiefly out of the difficulty of enforcing and inculcating rational doctrines upon the subject of combustion, and of getting persons to adopt new systems of construction in regard to furnaces and fire-places, new methods of stoking and managing the fire, and new kinds of fuel; and it is astonishing to observe the obstinacy and perverseness which prevail in these respects amongst the masters as well as the men. There is another cause too, which no doubt has had its influence in retarding th adoption of means for diminishing the smoke nuisance which is the shoals of quacks and ignorant empyrics an impostors who have embarked in these speculations; s that till stringent and coercive measures are adopted i regard to it, founded upon scientific and rational principles, we must be content to continue breathing a tainte air, which fouls the organs of respiration, encrusts ou buildings, and covers our books, pictures, and every ar ticle of furniture with an enamel of soot, and whicl dims the atmosphere to such an extent as materially t shorten the duration of metropolitan daylight.

That all these evils may be got rid of admits of n doubt, and ultimately with economy and convenience though the first introduction of the remedies will pro bably be attended by many practical difficulties, and con siderable inconvenience and expense. One remedy, an the most obvious, consists in the substitution of coke anthracite, and certain other smokeless fuel, for the bi tuminous and eminently smoke-generating varieties o coal now in common use. Another is, the constructio of fireplaces and furnaces which shall not indeed burn smoke, but prevent its formation. It must be allowe that there are many practical difficulties in the way, rathe perhaps of the application than of the invention or per fection of these contrivances; but experience has show that none of these are of such a nature or magnitud that they may not be overcome by perseverance and skill They all merge into one common principle, that of mix ing air with the combustible vapours and gases generate by the action of heat on pit coal, so that by virtue of a du supply of oxygen they may be made to burn with flame and become entirely converted into incombustible an transparent invisible vapours and gases, instead of being as they now are, only partially burned, by which thei carbon is precipitated, and escapes, together with th other imperfectly consumed matters, into the air. Th foundation of a *practical* inquiry into the subject of th prevention of smoke has been laid by Mr. C. W. Williams of Liverpool (*Essays on the Combustion of Coa and Prevention of Smoke*). The theoretical details ar essentially blended with the whole doctrine of heat; bu the investigations which most essentially bear upon them will be found in *Sir H. Davy's Researches into the Philosophy of Flame.*

SMOKE SAIL. A small sail hoisted before the funne of the galley, when the ship is at anchor head to wind to screen the quarter deck from the smoke.

SMORZATO. (It. *extinguished.*) In Music, a term denoting that the violin bow is to be drawn to its full extent, but gradually lighter till the sound is nearly lost.

SMU'GGLING. The offence of defrauding the revenue by the introduction of articles into consumptio without paying the duties chargeable upon them. It may be committed indifferently either upon the excise or customs revenue.

Origin and Prevention of Smuggling. — This crime which occupies so prominent a place in the criminal legislation of all modern states, is wholly the result o vicious commercial and financial legislation. It is the fruit either of prohibitions of importation, or of oppressively high duties. It does not originate in any depravity inherent in man; but in the folly and ignorance o legislators. A prohibition against importing a commodity does not take away the taste for it; and the imposition of a high duty on any article occasions a universal desire to escape or evade its payment. Hence the rise and occupation of the smuggler. The risk of being detected in the clandestine introduction of commodities under any system of fiscal regulations may always be valued at a certain average rate; and wherever the duties exceed this rate, smuggling immediately takes place. Now, there are plainly but two ways of checking this practice, — either the temptation to smuggle must be diminished by lowering the duties, or the difficulties in the way of smuggling must be increased. The first is obviously the more natural and efficient method of effecting the object in view; but the second has been most generally resorted to, even in cases where the duties were quite excessive. Governments have uniformly almost consulted the persons employed in the collection of the revenue with respect to the best mode of rendering taxes effectual; though it is clear that the interests, prejudices, and peculiar habits of such persons, utterly disqualify them from forming a sound opinion on such a subject. They cannot recommend a reduction of duties as a means of repressing smuggling and increasing revenue, without acknowledging their own incapacity to detect and defeat illicit practices; and the result has been, that instead of ascribing the prevalence of smuggling to its true causes, the officers of customs and excise have almost universally ascribed it to some defect in the laws, or in the mode of administering them, and have proposed repressing it by new regulations, and by increasing the number and severity of the penalties affecting the smuggler. As might have been expected, these attempts have, in the great majority of cases, proved signally un-

successful. And it has been invariably found that no vigilance on the part of the revenue officers, and no severity of punishment, can prevent the smuggling of such commodities as are either prohibited or loaded with oppressive duties. The smuggler is generally a popular character; and whatever the law may declare on the subject, it is quite ludicrous to expect that the bulk of society will ever be brought to think that those who furnish them with cheap brandy, geneva, tobacco, &c. are guilty of any very heinous offence.

"To pretend," says Dr. Smith, "to have any scruple about buying smuggled goods, though a manifest encouragement to the violation of the revenue laws, and to the perjury which almost always attends it, would, in most countries, be regarded as one of those pedantic pieces of hypocrisy, which, instead of gaining credit with any body, seems only to expose the person who affects to practise them to the suspicion of being a greater knave than most of his neighbours. By this indulgence of the public, the smuggler is often encouraged to continue a trade which he is thus taught to consider as in some measure innocent; and when the severity of the revenue laws is ready to fall upon him, he is frequently disposed to defend with violence what he has been accustomed to regard as his just property; and from being at first rather imprudent than criminal, he at last too often becomes one of the most determined violators of the laws of society." (*Wealth of Nations*, vol. iii. p.491.)

To create by means of high duties an overwhelming temptation to indulge in crime, and then to punish men for indulging in it, is a proceeding completely subversive of every principle of justice. It revolts the natural feelings of the people; and teaches them to feel an interest in the worst characters — for such smugglers generally are, — to espouse their cause, and avenge their wrongs. A punishment which is not proportioned to the offence, and which does not carry the sanction of public opinion along with it, can never be productive of any good effect. The true way to put down smuggling is to render it unprofitable, to diminish the temptation to engage in it; and this is not to be done by surrounding the coasts with cordons of troops, by the multiplication of oaths and penalties, and making the country the theatre of ferocious and bloody contests in the field, and of perjury and chicanery in the courts of law; but by repealing prohibitions, and reducing duties, so that their collection may be enforced with a moderate degree of vigilance, and that the forfeiture of the article may be a sufficient penalty upon the smuggler. It is in this, and in this only, that we must seek for an effectual check to illicit trafficking. Whenever the profits of the fair trader become nearly equal to those of the smuggler, the latter is forced to abandon his hazardous profession. But so long as prohibitions or oppressively high duties are kept up, or, which is, in fact, the same thing, so long as *high bounties* are held out to encourage the adventurous, the needy, and the profligate to enter on this career, we may be assured that armies of excise and custom-house officers, backed by the utmost severity of the revenue laws, will be insufficient to hinder them. (For full particulars respecting the law of smuggling, &c. see the *Com. Dict.*)

SMUT. A disease incidental to corn crops, by which the farina of the grain in the whole body of the seed is converted into a black soot-like powder. If an ear of corn affected by this disease be smartly struck with the finger, the powder will be dispersed like that of the fungus known as *Lycoperdon bonista*, the common puff-ball found in pastures, but darker; and if a portion of the powder be moistened and examined with the microscope, it will be found to consist of innumerable minute transparent globules. Some attribute the smut to the richness of the soil, and others consider it as a hereditary disease transmitted by one generation to another through the seed. Willdenow and Mirbel regard it as a small fungus; but Bauer believes it to be a proper disease, indicated by a morbid swelling of the ear. Some cultivators steep the grain of smutty corn in a weak solution of arsenic before sowing; but others deny the efficacy of this preparation. Smutty grain is separated from such as may be used for seed, or for grinding into flour, by being rapidly whirled round in a cylinder lined with brushes; or by steeping in water, when the smut from its lightness floats on the surface. The safest mode for the farmer to pursue is never to sow grain from a field in which the smut has prevailed.

SNAKE ROOT. This term is applied to the root of the *Aristolochia serpentaria*, a native of Virginia: it is a fibrous, aromatic, and bitterish root. The infusion is occasionally used as a tonic and diaphoretic: in typhoid fevers it is a good adjunct to Peruvian bark, and to quinia.

SNAKE WOOD. The wood of the *Strychnos colubrina*. Supposed to be an antidote to the poison of certain snakes.

SNEE'ZING. A convulsive action of the respiratory organs, brought on by irritation of the nostrils. Violent fits of sneezing have occasionally attacked persons, and are even said to have proved fatal; recourse must in such cases be had to soothing the nasal membrane by the application of warm milk and water, or decoction of poppies.

SNIPE. The common name of the *Scolopax gallinago*, Linn. This bird is a plentiful species in most parts of Great Britain. In wet seasons it resorts to the hills and higher grounds; in ordinary seasons it frequents marshes. Its principal food is worms, in quest of which it penetrates the soft earth with its long and slender bill, which is especially organized for that purpose.

SNOW. (Ger. schnee.) Congealed water, which falls from the bosom of the atmosphere. Very little is yet known respecting the formation of this meteor. It has not been ascertained, for instance, whether the clouds which produce it are composed of vesicular vapours, or of frozen particles; nor whether the flakes are completely formed before they begin to descend, or receive an increase in passing through the lower strata of the atmosphere. The temperature of the flakes, and the circumstances which determine their form and volume, are likewise unknown. The only observations which may be considered as in any degree complete are with reference to the different forms which the flakes assume. This subject was considered by Kepler, Hooke, Cassini, Muschenbroek, and many others; but the most interesting series of observations we possess are those of Scoresby (*Account of the Arctic Regions*, 1820), who has reduced the different forms into classes, and given a number of excellent representations of the flakes in different states. Generally speaking, when examined with the microscope they present modifications of stelliform and hexagonal crystals; and frequently they consist of a star of six rays formed of prisms united at angles of 60°, from which other prisms shoot at similar angles, giving the whole an appearance of exquisite beauty and great regularity. The variety of modifications is probably owing to the state of the atmosphere when the snow is formed. If the crystallization takes place when the air is calm, the crystals will be regularly formed; on the contrary, they will be irregular and imperfect when the air is much agitated. Sometimes the flakes present no traces of crystallization.

Snow is much less dense than ordinary ice. The bulk of a given weight of ice is only about a ninth part greater than that of the water from which it is formed, while the bulk of new-fallen snow is ten or twelve times greater than that of the water obtained by melting it.

At moderate elevations above the sea, and in the mean latitudes, snow most frequently falls after some days of pretty hard frost, and when the temperature of the air, though still a few degrees above the freezing point, is sensibly mitigated. On this circumstance is founded the remark that it cannot snow in very severe cold; and though the remark does not always hold good, it will do so generally, for two reasons: — in the first place, the air which comes from very cold regions contains a small portion of watery vapour; and secondly, because the formation of clouds, by diminishing the radiation, necessarily mitigates the severity of the cold.

As snow can only be formed when the temperature of the atmospheric strata containing the aqueous vapour is below the freezing point, it is obvious that if the snow in falling passes into strata of a higher temperature, it will be melted before arriving at the surface of the earth. Hence it follows that it never snows in the torrid zone, nor in the heats of summer, excepting on the tops of very elevated mountains.

Red Snow. — It had been remarked by the ancients that snow sometimes assumes a red tint, and Pliny ascribes the cause to age: — *Ipsa nix vetustate rubescit.* Many modern observers have described and examined this curious phenomena, which appears to be met with in all parts of the world. Saussure observed red snow on the Bevern in 1760, and on St. Bernard in 1778; and he supposed the colouring matter to consist of a vegetable dust. Ramond met with it in the Pyrenees, Captain Ross in Baffin's Bay; Parry, Franklin, and Scoresby collected it in still higher northern latitudes; and it has been found abundantly in New Shetland in latitude 70° south. Among the Alps it is generally found in low sheltered spots, and penetrating to the depth of two or three inches; or rather the strata in which it is found (for it occurs overlaid at considerable depths) seldom exceed two or three inches in thickness. The colouring matter of this singular substance has been examined by Wollaston, R. Brown, De Candolle, Thenard, Bauer, &c. Dr. Wollaston first remarked that it is composed of minute spherical globules, which have a transparent envelop, and are divided into seven or eight small cells filled with a species of red oil insoluble in water. Mr. R. Brown and De Candolle supposed the globules to be a kind of algæ. Mr. Bauer (*Phil. Trans.* 1820) found the globules to be exactly identical in snow collected in Baffin's Bay and New Shetland; and he supposed them to be small mushrooms of the genus *Uredo*, forming a peculiar species, to which he gave the name of *Uredo nivalis.*

Snow Line, or Limit of Perpetual Snow.— Since the temperature of the atmosphere continually diminishes in ascending from the surface into the higher altitudes, there must be in every latitude a certain limit of elevation at which the air attains the temperature of freezing water. This limit is called the snow line, or line of perpetual congelation; and the mountains which rise above it are covered with perpetual snow. Within the tropics the temperature varies little throughout the year, and hence the snow line is distinctly marked; but in countries remote from the equator the limit of congelation rises in summer and descends in winter through a band or zone of considerable breadth. The line of *perpetual* congelation is of course the summer limit. The altitude of the snow line, however, is not dependent upon latitude alone; but also on the configuration and aspects of the mountain chains, the extent and temperature of the surrounding plains, the quantity of snow that falls annually, and the multitude of causes which influence the climate of a country. (*See* CLIMATE.) On the Himalaya chain, for example, the limit of perpetual congelation on the northern side is at an elevation exceeding by upwards of 4400 feet that on the southern side, though the latter is directly exposed to the sun; a circumstance which Humboldt ascribes to the radiation from the great plain of Thibet, the general serenity of the climate, and the rarity of snow in an exceedingly cold and dry atmosphere. No dependence, therefore, can be placed on any general rule for estimating the height of the snow line, and it affords an exceedingly fallacious indication of the altitude of mountains. The following table is given by Humboldt in his *Fragmens Asiatiques*, p. 549. The elevations stated are the heights of the line of perpetual congelation above the level of the sea, and the measures are reduced to English feet.

Mountain Chains.	Latitude.	Elevation.
		Feet.
Cordilleras of Quito	0° — 1½° S.	15,730
Cordilleras of Bolivia	16 — 17¾	17,060
Cordilleras of Mexico	19 N.	15,030

(See, in addition to the works already cited, Humboldt, *Mémoire sur la Limite de Neige perpetuelle dans les Montagnes de l'Himalaya, et les Regions Equatoréales*, in the *Annales de Chimie*, tome xiv.)

SOAP. (Gr. σαπων, Lat. sapo.) This useful compound is obtained by the action of alkaline upon oily substances. There are, accordingly, a great variety of soaps; but those commonly employed may be considered under the heads of, 1. Fine white soaps, scented soap, &c.; 2. Coarse household soaps; 3. Soft soaps. The materials used in the manufacture of white soaps are generally olive oil and carbonate of soda: the latter is rendered caustic by the operation of quicklime, and the solution thus obtained is called *soap ley*. The oil and a weak ley are first boiled together, and portions of stronger ley are gradually added till the soap, produced by the mutual action of the oil and alkali, begins to become tenacious and to separate from the water; some common salt is then generally added to promote the granulation and perfect separation of the soap; the fire is then drawn, and the contents of the boiler allowed to remain for some hours at rest, so that the soap may more completely collect. When it is perfect it is put into wooden frames or moulds; and when stiff enough to be handled, it is cut into oblong slices and dried in an airy room. Perfumes are occasionally added, or various colouring matters stirred in whilst the soap is semifluid to give it a mottled appearance. The Spanish soap is *marbled* by stirring into it a solution of sulphate of iron, which is decomposed by the soap, and black oxide of iron separated in streaks and patches through the mass. The action of the air converts the exterior into red oxide, whilst the interior long retains its black colour: hence a slice of this soap presents a black mottled centre, surrounded by a reddened external layer.

Common household soaps are made chiefly of soda and tallow; or if potash is used, a large addition of common salt is made to harden the soap, which it probably effects by the transference of soda. Yellow soap has a portion of rosin added to it. Soft soaps are generally made with potash instead of soda, and fish oil. The common soft soap used in London is a compound of this kind; it has a tenacious consistence, and appears granulated. Soap is soluble in pure water and in alcohol; the latter solution *jellies* when concentrated, and is medicinally known under the name of *opodeldoc*. When carefully evaporated the soap remains in a gelatinous state, which forms, when dry, the article sold under the name of *transparent soap*.

The earths and common metallic oxides form *insoluble soaps;* and accordingly these are precipitated when earthy and metallic salts are added to solution of soap. It is the sulphate of lime and carbonate of lime in common spring water which thus render it unfit for washing, and give it what is termed *hardness;* and, upon this principle, a spirituous solution of soap is a simple and valuable test of the fitness of any river or spring water for the purposes of the laundry. If it merely renders the water slightly opalescent, as is the case with rain and other soft waters, it may be used for washing; but if it become milky, it is usually too hard to be conveniently employed; and when we wash or shave with hard water, the separation of the insoluble calcareous soap is extremely disagreeable: it adheres to the skin, and soils instead of cleansing it.

The chemical nature of soap has been laboriously examined by Chevreul, who has shown that the alkali in the process of saponification converts the oil into peculiar *acids*, as he terms them; the elain of the oil forming *oleic acid*, and the stearine *margaric acid:* so that soluble soaps are oleates and margarates of soda and potash. He has enumerated several other fatty acids similarly produced.

All new soaps contain a considerable portion of adhering water, a great part of which they lose when kept in a dry place; hence the economy and excellence of *old* soap; and hence the dealers in soap generally keep it in a damp cellar, that it may not lose weight by evaporation; or, as it is said, sometimes immerse it in brine, which does not dissolve it, but keeps it in its utmost state of humidity.

Soap may be considered as a necessary of life; in all civilized countries its consumption is immense. According to Pliny, the invention of soap must be ascribed to the Gauls, by whom, he says, it was composed of tallow and ashes, though the German soap was considered the best. Hence the Lat. sapo, which by a slight transposition of letters has become *soap*, is probably derived from the old German sepe (now written *seife*). The great seats of the soap manufacture in Great Britain are Liverpool, London, Runcorn, Bristol, Bromsgrove, Brentford, Hull, and Glasgow. Thus, of 154,796,853 lbs. of hard soap made in 1839, Liverpool furnished 43,546,119 lbs.; London, 38,065,175 lbs.; Runcorn, 11,034,324 lbs.; Bristol, 7,512,440 lbs.; Bromsgrove, 5,854,213 lbs.; Brentford, 4,938,444 lbs.; Hull, 4,666,435 lbs.; and Glasgow, 5,858,844 lbs. Of 14,874,963 lbs. of soft soap made in the same year, Liverpool furnished about one half, the rest being supplied by Glasgow, Bradford, Aberdeen, Paisley, &c. The manufacture of hard soap is subject to a duty of 1½*d.* per lb., that of soft soap to a duty of ⅞*d.* per lb.

SOAP STONE. A mineralogical synonym of steatite.

SOAVE, SOAVEMENTE. (It. *sweet, sweetly.*) In Music, a term denoting to the player that the music to which it is prefixed is to be executed with sweetness.

SO'BRIQUET. In French, a burlesque appellation or *nickname*. The word has been variously derived from the Lat. subridiculum, subrusticum, and the Gr. ὑβϱιστιϰον, &c. There is a curious dissertation in vol. xiv. of the *Histoire de l'Academie des Inscrip.* on the authority of these appellations in history.

SO'CAGE (Mod. Lat. socagium; from the Anglo-Saxon soke, or *plough*), denotes, according to Blackstone, in its original and most extensive signification, a tenure by any certain and determinate service. The sokemen at and immediately before the Norman conquest appear to have been in the lowest ranks of free cultivators of the land, being classed along with the villein in a law of Edward the Confessor. But by the time when the works of Bracton and the author of *Fleta* were compiled, socage had come to signify any tenure not military or quasi-military; *i.e.* either where military services were due (tenure in chivalry or by knight service), or other services of an honorary kind, such as by the French feudal law were due on what were called imperfect fiefs (tenure by grand serjeanty). Socage, therefore, comprehended various descriptions of tenure, and has been generally divided into *free* and *villein* socage. In free socage, the services were certain, and, in the feudal sense, not base or dishonourable, as the payment of an annual rent; and none of the feudal incidents of wardship, &c. were demandable in respect of lands so held, although certain aids and reliefs were peculiar to socage as well as to knight service. By the stat. 12 C. 2. c. 24., when military tenures were abolished, all sorts of tenures held of the king and others (except frank-almoign, copyhold, and the honorary part of grand serjeanty) were turned into tenure by free or common socage. Villein socage was a species of tenure in lands held of the king by certain villein services, but certain and determinate; from which mixed species of tenure arose that in ancient demesne. Lands so held are deemed to be in certain respects copyhold; and these were within the exceptions of the statute 12 Charles 2., and still subsist.

SOCI'ETY. (Lat. socius, *a companion.*) The term usually applied to an association formed for the promotion of some object, either literary, religious, benevolent, political, or convivial. Associations formed for commercial purposes are usually styled *companies;* which see. Literary societies extend their attention to all the sciences and literature generally, or to particular divisions of each. The chief literary societies of Europe have been noticed under ACADEMY. The purposes for which *benevolent* and *religious* societies are formed will be best inferred from the epithets with which they are connected; thus *temperance* societies are established with a view to promote sobriety, *mendicity* societies for the relief of the indigent, &c. There is no feature, perhaps, which distinguishes a civilized from a savage state more than the establishment of such societies; and in this view England has a right to claim a place in the foremost ranks of civilization, whether we regard the number or the principles of the management of its religious and benevolent institutions. It would be impossible in this place to give even the names of the chief societies of this nature scattered throughout the country; but the reader will find an account of them in the various reports published from time to time by their respective directors, and embodying a mass of information respecting them at once amusing and instructive.

Societies formed for *convivial* or *political* purposes are most usually denominated *clubs,* — a term which may be truly said to be exclusively English, and which embraces so many complex ideas that it is all but impossible to reduce it within the limits of a precise definition. The origin of clubs may be said to date from the end of the 17th century. It would be superfluous to call to the reader's remembrance the beau ideal of a club which Addison has drawn in the *Spectator,* — the Kit-Kat club, which numbered among its members all the most distinguished persons of the day; the Scriblerus club, of which Swift, Harley, Pope, Gay, and Arbuthnot were members; or that still nearer our own times originally held at the Essex Head, which was ennobled by the genius of Johnson, Burke, Reynolds, Goldsmith, Wyndham, and Fox. They were originally instituted solely for convivial purposes; but in the course of time the term *club* was successively adopted by various political associations, both in this country and on the Continent. Since the commencement of the present century, the chief clubs have been either of an avowed political character, as the Carlton, Boodle, and the Reform clubs; or devoted exclusively to certain classes, as the United Service, the Oxford, and Cambridge; or open to all gentlemen on election, without regard to political party or profession, as the Athenæum, Wyndham, &c. There are about forty clubs in the metropolis. They consist each of a limited number of members, varying from 1000 to 1500, who are admitted by ballot, and pay from ten to twenty-five guineas on their admission, and an annual subscription varying from five to ten guineas. We need scarcely add, that the club-houses are, generally speaking, splendid edifices, which add much to the magnificence of the streets and squares in which they are situated.

The latest appropriation of the term *club* has been made by several associations,—such as the Roxburgh club of London, the Bannatyne of Edinburgh, and the Maitland of Glasgow,—which were formed for the purpose of printing original MSS., which would not otherwise have seen the light, or of rescuing rare productions from oblivion by reprinting them from scarce and valuable editions.

SOCI'NIANS. The followers of Socinus, the uncle and the nephew, both of the same name, and celebrated for similar opinions concerning the nature of Christ. The nephew, Faustus Socinus, was the principal founder of the sect. He was an Italian, born at Sienna in 1539; who, after publishing a treatise upon the nature of the Saviour, desired to be admitted into a society of Unitarians already existing in Poland. Their opinions do not appear to have precisely corresponded with his, and admission was refused him; nor did he effect during his lifetime the institution of any distinct congregation; but the views which he disseminated in his writings were gradually referred to and adopted by many ministers and religious communities, especially in Poland, where Crellius, Wolgozenius, and others published a Socinian system of theology, comprised in the *Bibliotheca Fratrum Polonorum.*

Since the death of Socinus, the theologians who have asserted the mere humanity of Christ have been generally denominated Socinians. The doctrines, however, to which that appellation can with strictness be applied are not precisely equivalent to those of the modern Unitarians. The Socinian denies the existence of Christ previous to his birth of the Virgin Mary: he allows, however, that that birth was miraculous, and considers the Saviour as an object of peculiar reverence and an inferior degree of worship. By the term Mediator, as applied to Christ, he understands that in establishing the new covenant he was the medium between God and man; and of his sacrifice he says that as the Jewish sacrifices were not made for the payment of sins, but for the remission of them, so also the death of Christ was designed for the remission of sins through God's favour, and not for the satisfaction of them as an equivalent. (See *Mosheim,* vol. iv. transl. 1790, p. 485. &c. art. "Unitarians.")

SOCK. (Lat. soccus.) The name given to the peculiar kind of shoe worn by the ancient Roman comedians; hence used metaphorically for comedy itself. *See* BUSKIN.

SO'CLE. (It. zoccoli, *a shoe.*) In Architecture, a square member, whose breadth is greater than its height; used instead of a pedestal for the reception of a column. It differs from a pedestal in being without base or cornice.

SOCRATIC PHILOSOPHY, in a more extensive sense, is used to comprehend the whole development of philosophy of Greece from Socrates to the Neo Platonists. The title is so far just, as all the schools of this period, with the single exception of the Epicurean, called themselves by the name of Socrates, and arrogated to themselves the merit of exclusively propagating the true doctrines of Socrates. But in a narrow and more proper signification, it signifies the peculiar direction and method which Socrates gave to philosophical inquiry. Rightly to understand this, a brief retrospect of the previous state of philosophy is requisite. By the due course of things, the Ionian and other earliest philosophers of Greece directed themselves to the study of external nature; which, as the outward condition of man's existence, attracts and constrains his attention, and so becomes the root and source of his intellectual life also. In this state of mental development man is led to identify himself with the physical objects which are around him, and to form a single and exclusive science, — that of universal nature. But on a wider range of observation, man began to perceive that his faculty of reason is not a physical power, but different in kind, and peculiar to himself. And so the belief in the affinity of man to the powers of the surrounding world was gradually weakened. Philosophy, then, had now arrived at the point where either the distinction of the ethical and the physical must be set forth in clear evidence; or else, by adhering to the previous direction of thought, the light which had been, however unconsciously, kindled must be obscured and extinguished. To the latter result the labours of the Sophists directly tended; for Archelaus, the physiologist, had opened the way, by his disquisitions into the nature and constitution of law and custom, in which, starting from a physical point of view, he declared reason to be simply a power of nature, and right to have no other foundation than might. Such attempts, however, served to stimulate rather than to repress that inquiry into the nature of the moral and rational, as distinct from the physical, while other considerations were at this period establishing them as independent sciences. But to admit the claims of both as two conflicting sciences, with equal pretensions to universality, was inconsistent with the unifying tendency of philosophy; and a more scientific range of thought was required, adapted to reconcile and combine their opposite conclusions. Such a view could only be presented by logical or dialectical investigations, which, from the nature of science itself, might show that it is essential to the completeness and perfection of science that it should embrace both nature and reason at once. It is this perception of the unity of science which constitutes the true merit of Socrates as a philosopher. In all the accounts of him which either Xenophon or Plato furnish, we invariably discern the attempt, at least, to embrace every question within the light of universal science; and to prove that every species of knowledge, if legitimate, can be pointed out and shown to be a necessary member of the general idea of science.

It was not the object of Socrates to establish any perfectly evolved system of doctrine, so much as to awaken by his discourses a new and more comprehensive pursuit of science, which, no longer one-sided and confined to special branches of inquiry, but convinced of its universality, should direct itself to all that is knowable. But beneath this conviction of the universality of science, and the oneness of its object-matter, we distinctly trace that division of the latter into dialectics, physics, and ethics, which his successors more distinctly established. To these heads, therefore, without expressly ascribing them to Socrates, it will be convenient, for the purpose of classification, to refer his several doctrines.

Under the head of dialectics, we have, on the testimony of Aristotle (*Met.* xiii. 4.), to ascribe to Socrates two of the very first principles of science,—the inductive method of proof, and the definition of ideas. The object which Socrates had in view by the latter was, by the definition of ideas, to determine what the thing is in itself, or its essence. As to the former, we are told by Xenophon that when Socrates wished to come to a decision on any point, his investigations proceeded from propositions generally received as true; and if we are told that he often preferred to take up trifling and improbable po-

sitions, it was from a conviction that every thought, however imperfect as a work of reason, must necessarily involve the idea of certainty. Another feature of the Socratic method was to place the particular idea to be examined in a great variety of combinations; a procedure which is evidently based on a conviction of the connection of all scientific thought, and implying that every particular thought must, if it contain any degree of certainty, maintain its validity under every possible combination. Such was the true Socratic method of dialectics, which derived its name from the *form* of dialogue (διαλέγειν) in which it was accidentally worked out; while, on the other hand, the term *Socratic method* has, in modern times, been confined to signify nothing more than this outward form of arguing by question and answer, to the exclusion of its essential characteristics. Socrates, indeed, did not evolve any systematic doctrine of the form and subject-matter of science. He was satisfied with exercising his disciples in its form, and with infixing on their minds the pregnant truth, that the legitimacy of every branch of knowledge must be tested by its agreement with all others; and that every thought of man must give an account of itself, and have its root in a knowledge of his own and the divine nature.

This knowledge was the end of his physical inquiries, which were based on the general principle that all the objects of nature are only so far worthy of inquiry as they exhibit traces of intelligence and design. The self-knowledge which the Delphian oracle had enjoined upon him Socrates held to be impossible, while man is ignorant of the universal principle whence are the issues of all things, and, consequently, of the system of nature in the midst of which man is placed. In order to oppose the atheism which prevailed in his day, Socrates examined the causes of the existing unbelief, and referred to the proofs of divinity which the wise order of natural things exhibits. As the prevailing scepticism had its origin in the denial of whatever is unseen and imperceptible to the outward senses, he argued that the soul, which is the ruling principle within man, is yet not discernible; but still its existence is admitted, and it participates in the divine nature. Whoever, therefore, can get rid of the weak desire of seeing the Deity under some palpable form, may easily recognize his operations within his own mind, where God has implanted a consciousness of his presence. But he further held, that not only man, but the whole universe, is under the rule of an intelligent governor; that all is formed for some wise end, and affords evidence of that supreme reason from which man's rational soul derives and has its being. In the consideration of individual things, not less than of the universe, the sole question with Socrates was to establish intelligence as the ruling principle of all. This affords an explanation of his low estimate of the existing physiology, which has not unfrequently been objected to him. His contempt for it was grounded on the same reason as Bacon's aversion for the schoolmen. It stopped at secondary causes, and did not remount to the one first cause, which Socrates believed could only be found in intelligence beneficently disposing all things for the best. Although the earlier philosophers did not entirely neglect the marks of design which may be discovered in the universe, still they confounded nature with intelligence. Socrates, on the contrary, laboured to show that reason is above nature, and that the natural is merely subservient to intellectual ends. Whatever is without reason is contemptible; and the corporeal is of no value except so far as it ministers to the rational soul. Into the nature of the divine essence he did not inquire, but was content with asserting the principle, that the Deity is the supreme reason, and must be honoured by man as the source of all things, and of all phenomena, and as the end of all human endeavours. Lastly, from the divinity within man, the intelligence visible in the universe, and the worthlessness of body, except as an instrument of reason, Socrates deduced the immortality of the soul as a necessary consequence.

The object-matter of Socrates' disputations exhibit a great preference of ethical to physical topics. This may partly be explained by the fact, that in ethics a scientific spirit of inquiry had yet to be awakened, while physics had been long and extensively cultivated. Partly, also, it had its origin in the mental state of Athens at this period. The art of sophistry, which Socrates was seeking to overthrow, was based on the monstrous dogmas, that there is no truth for man; that he is the wisest who, rejecting all hope of it, is skilful enough to hide from others his own ignorance and incapacity by an ingenious display of artifices and forms. Successfully to combat these pernicious views, an appeal must be made to those general principles of belief which are implied in and indispensable to the right conduct of life; a strong hold must be taken of what is fixed and indestructible in man in his moral convictions. But, content with thus awakening man to a consciousness of the moral destiny of man, and his moral responsibility, he did not seek to construct an elaborate system of ethics. Having projected the ideal of science, both in its extent and form, he contributed little to its realization, either as a whole, or in its parts. A few propositions are necessary, however, to exhibit the true spirit of the Socratic ethics. Man naturally strives after happiness; but in this we must distinguish between accidental good fortune (εὐτυχία), and that which results from science and industry (εὐπραξία). The essence, therefore, of the moral act consists in the free agency of man. All virtue is one; and no act performed without a clear perception of its nature and tendency is either good or evil. There is no merit in a virtuous action unless it has been undertaken as such, intentionally and knowingly, the will being determined thereto by the notion of good. But this natural sense of right may be overborne by a stronger motive. This innate perception of good, therefore, like all other human faculties, stands in need of education to expand and strengthen it. Virtue may be taught, since it consists in the science of good.

SOD. The grassy surface of the soil pared off with a portion of the earth; in other words, turf.

SO'DA. Natron; mineral alkali. This important and useful substance is an oxide of sodium. Sodium was discovered by Davy in 1808. It is a metal much resembling potassium in its general characters. It is soft, malleable, fusible at 190°, and burns when heated in contact of air. When thrown upon water it does not burn, but floats about upon the surface, and rapidly disappears, being converted into soda, which is dissolved in the water, and gives it an alkaline reaction. The specific gravity of sodium is 0·97. By the quantity of hydrogen evolved during the action of sodium on water, we learn that soda, or oxide of sodium, consists of 1 equivalent of sodium = 24, and 1 of oxygen = 8. The equivalent of soda, therefore, is 32. The commercial demands for soda are chiefly supplied from two sources: the combustion of marine vegetables, such as common sea-weed and the *Salsola soda*, which furnish the impure alkalies called *kelp* and *barilla*; and the decomposition of common salt, or rather perhaps of sulphate of soda, obtained by the decomposition of salt by sulphuric acid. Carbonate of soda forms large rhombo-prismatic crystals, composed of 32 soda + 22 carbonic acid + 90 water. They fuse in their water of crystallization at about 150°, and it may be entirely expelled by exposure to heat. They effloresce when exposed to air. Sulphate of soda, or Glauber's salt, is the result of the action of sulphuric acid upon common salt. (*See* MURIATIC ACID.) It consists of 32 soda + 40 sulphuric acid; and the crystals are constituted of 72 dry sulphate and 90 water: they are efflorescent, and soluble in about 3 parts of cold water. When sodium is introduced into chlorine it immediately combines with it to form chloride of sodium, or common salt; if heated in the gas, it burns very vividly: 24 parts of sodium combine with 36 of chlorine to form 60 parts of this important and well-known compound. (*See* SALT.) When chlorine gas is passed into a weak solution of caustic soda it is absorbed, and a useful bleaching and disinfecting solution is obtained, which has been called *Labarracque's disinfecting soda liquid*.

SO'DALITE. A mineral composed chiefly of silica, alumina, and soda.

SODA WATER. This common and refreshing beverage is, as usually prepared, a supersaturated solution of carbonic acid gas in water. True *soda water* was formerly prepared (and is still by some manufacturers) for medical use, chiefly as a remedy for heartburn, and certain forms of dyspepsia and calculous complaints; and consisted of one, two, or three drachms of carbonate of soda, dissolved in a pint of water highly impregnated with carbonic acid. This is often a valuable remedy; but would sometimes be attended by mischievous results, especially if indulged in to the extent to which some persons pursue the use of soda water. The mere aqueous solution of carbonic acid, which is made by forcing the gas into water by a condensing pump, and under a pressure of six or eight atmospheres, is an agreeable and generally speaking harmless diluent.

SOD-BURNING. Burning of turf taken from the surface of worn-out pasture lands for the sake of the ashes as manure, &c.

SODIUM. *See* SODA.

SOFFITT. (It. soffitta, *overlaid*.) In Architecture. *See* LACUNAR.

SO'FI. A Persian word, which is employed to designate religious persons, otherwise termed Dervishes. It is probably a corruption of the Greek sophos, *wise*. Sofi was the surname borne by the ancestors of the kings of Persia of the race preceding that which now occupies the throne; and Shah Ismael Sofi, the first monarch of that race, also bore it; hence by European writers of the 16th and 17th centuries it was used erroneously as a title of the king of Persia.

SO'FISM, or SUFISM. The mystical doctrines of the class of Mohammedan religionists called Sofis. This name is indeed generally applied in the East to persons living together in a monastic way, and professing an

ascetic life. But the tenets peculiarly denoted by the name of Sufism are those of a sect which is said to be gaining ground extensively in oriental countries, especially among the educated classes of Mohammedans. These tenets, like those of the Quietists and other Christian sects of mystics, are founded on a notion of the union of the human soul with the divinity by contemplation and the subjugation of the appetites; but, as has been too frequently the case among Christians also, they have afforded a cover for the most licentious lessons of refined debauchery. In the last volume of Mr. Buckingham's *Oriental Travels*, containing a narrative of his journey in Mesopotamia, will be found a singular account of one of these monastic philosophers, his doctrines and conduct. The principles of Sufism appear also to have a remarkable affinity, in some respects, with those pantheistic notions which are prominent in the system of the Bramins, and seem to form the very foundation of the still more widely extended religion of Buddha.

SO'FTENING. In Painting, the blending of colours into each other.

SOIL. The primitive earths in a state of mixture with organized matter fit for the growth of plants. The surface of the earth in every country on which plants have grown and decayed is properly denominated soil; while the earth at a foot or more beneath the surface, commonly called subsoil, is comparatively without organized matter, and is therefore properly denominated earth, clay, sand, gravel, lime, or mixed earth, rocks, or stones, as the case may be.

SOIRÉE. (Fr. soir, *evening*.) The term originally given by the French to certain evening parties held for the sake of conversation only, music, dancing, and similar entertainments being excluded; but the word has been since introduced into all the languages of modern Europe, and is now employed to designate most descriptions of evening parties in which ladies and gentlemen are intermixed, whatever be the amusements introduced. It is frequently applied in England to the public meetings of certain societies held for the advancement of their respective objects, at which tea and other refreshments are dispensed during the intervals of business.

SOKE. A territorial division, now subsisting in Lincolnshire. This term, according to the etymology given by Bracton, designated a precinct in which a particular lord exercised justice.

SOL. In Music, the fifth note of the gamut.

SOLANA'CEÆ. (Solanum, one of the genera.) A natural order of herbaceous or shrubby Exogens, inhabiting all parts of the world excepting the arctic regions. They are chiefly known from *Scrophulariaceæ* by their curved or spiral embryo, the plaited estivation of the flower, and the flowers being usually regular, with the same number of stamens as lobes. The first of these characters, however, is not of universal importance; the plaited corolla and symmetrical flowers are better marks of distinction. This order contains nightshade, henbane, mandrake, tobacco, stramonium, the potato, and the tomato, the leaves of all which are narcotic and exciting, but in different degrees,—from *Atropa belladonna*, which causes vertigo, convulsions, and vomiting; tobacco, which will frequently produce the first and last of these symptoms; henbane and stramonium, — down to some of the Solanum tribes, the leaves of which are so inert as to be used as kitchen herbs. Even in the potato plant, the narcotic acrid principle is found in the stem and leaves, and even in the rind of the tuber. But the principal part of the latter consists of starch; and the small quantity of deleterious matter being volatile and near the surface, is readily driven off by the heat used in cooking.

SOLA'NIA. The active principle of the *Solanum dulcamara*, or woody nightshade. It is a white alkaline substance, insoluble in water, but soluble in alcohol: its combinations with the acids are bitter.

SOLA'NO. A hot oppressive wind which occasionally blows in the Mediterranean, and particularly on the eastern coast of Spain. The solano is a modification of the sirocco.

SOLA'NUM TUBERO'SUM. The botanical name for the plant of which the potato is the root. The potato, which is at present to be met with everywhere in Europe, and forms the principal part of the food of a large proportion of its inhabitants, was entirely unknown in this quarter of the world till the latter part of the 16th century. It is a native of America; but whether of both divisions of that continent is doubtful. (Humboldt, *Nouvelle Espagne*, liv. iv. c. 9.) Some authors affirm that it was first introduced into Europe by Sir John Hawkins, in 1545; others, that it was introduced by Sir Francis Drake, in 1573; and others, again, that it was for the first time brought to England from Virginia by Sir Walter Raleigh, in 1586. But this discrepancy seems to have arisen from confounding the common or Virginian potato (the *Solanum tuberosum* of Linnæus) with the sweet potato (*Convolvulus battatas*). The latter was introduced into Europe long before the former, and it seems most probable that it was the species brought from New Granada by Hawkins. Sweet potatoes require a warm climate, and do not succeed in this country; they were, however, imported in considerable quantities, during the 16th century, from Spain and the Canaries, and were supposed to have some rather peculiar properties. The kissing comfits of Falstaff, and such like confections, were principally made of battatas and eringo roots. On the whole, we are inclined to think that we are really indebted for the potato (as well as for tobacco) to Sir Walter Raleigh, or the colonists he had planted in Virginia. Gerarde, an old English botanist, mentions in his *Herbal*, published in 1597, that he had planted the potato in his garden at London about 1590; and that it succeeded there as well as in its native soil, Virginia, whence he had received it. Potatoes were at first cultivated by a very few, and were looked upon as a great delicacy. In a manuscript account of the household expenses of Queen Anne, wife of James I., who died in 1618, and which is supposed to have been written in 1613, the purchase of a very small quantity of potatoes is mentioned at the price of 2*s*. a pound. The Royal Society, in 1663, recommended the extension of their cultivation, as a means of preventing famine. Previously, however, to 1684, they were raised only in the gardens of the nobility and gentry; but in that year they were planted, for the first time, in the open fields in Lancashire, — a county in which they have long been very extensively cultivated.

Potatoes, it is commonly thought, were not introduced into Ireland till 1610, when a small quantity was sent by Sir Walter Raleigh to be planted in a garden in his estate in the vicinity of Youghal. Their cultivation extended far more rapidly than in England; and have long furnished from 3-5ths to 4-5ths of the entire food of the people of Ireland!

Potatoes were not raised in Scotland, except in gardens, till 1728, when they were planted in the open fields by a person of the name of Prentice, a day labourer at Kilsyth, who died at Edinburgh in 1792.

The extension of the potato cultivation has been particularly rapid during the last forty years. The quantity that is now raised in Scotland is supposed to be from 10 to 12 times as great as the quantity raised in it at the end of the American war; and though the increase in England has not been nearly so great as in Scotland, it has been greater than during any previous period of equal duration. The increase on the Continent has been similar. Potatoes are now very largely cultivated in France, Italy, and Germany; and, with the exception of the Irish, the Swiss have become their greatest consumers. They were introduced into India some sixty or seventy years ago; and are now successfully cultivated in Bengal, and have been introduced into the Madras provinces, Java, the Philippines, and China. But the common potato does not thrive within the tropics, unless it be raised at an elevation of 3000 or 4000 feet above the level of the sea, so that it can never come into very general use in these regions. This, however, is not the case with the sweet potato, which has also been introduced into tropical Asia; and with such success, that it already forms a considerable portion of the food of the people of Java, and some other countries. So rapid an extension of the taste for, and the cultivation of an exotic, has no parallel in the history of industry: it has had, and will continue to have, the most powerful influence on the condition of mankind. But upon this part of the subject we must refer the reader for full particulars to the *Com. Dict.*, art. "Potatoes," from which the above historical sketch has been taken.

SOLAR CYCLE. A period of twenty-eight years. *See* CYCLE.

SOLAR SYSTEM, in Astronomy, consists of the sun, and all the celestial bodies whose motions are controlled by its gravitation, viz. the planets, satellites, and comets. *See* SUN, PLANET, &c.

SO'LDER. Plumbers' solder is an alloy of three parts of lead and one of tin; it is more fusible than lead, and readily adheres to clean surfaces of that metal when it is fused. Fine solder is a mixture of two parts of tin and one of lead; it fuses at 360°. It is used in the process of tinning copper. Hard soldering, or brazing, by which two surfaces of copper are made to adhere, is done by fusing together brass and zinc. When this solder is used, the copper requires to be heated to near its point of fusion.

SOLDIER. (Lat. soldarius; literally, *one who serves for pay*.) In general language, a person equipped and maintained by the state for the purpose of defending it from foreign aggression, of putting down intestine commotion; or, in short, of protecting its interests either at home or abroad, according to instructions issued by the civil government. *See* ARMY, ENLISTMENT, &c.

SO'LEA (Lat. *a slipper*), in Mammalogy, is the inferior surface of the foot or hoof.

SOLEA. The name of a genus of flat fishes (*Pleuronectidæ*), characterized as follows: — "Both eyes on

the right side; the mouth distorted on the side opposite the eyes; small teeth in both jaws, but confined to the under side only; form of the body oblong; dorsal and anal fins extending to the tail." The common sole (*Solea vulgaris*, Cuv.) is taken by trolling, and in enormous quantities, along our coasts, principally from Sussex to Devonshire; and excepting towards the latter end of February, and the beginning of March, when the soles are spawning, and are rather soft and watery, they are in good condition for the table throughout the year.

SO'LECISM. In Rhetoric and Grammar (Gr. *σολοίκισμος*, said to be derived from the name of a town in Cilicia, whose inhabitants spoke a barbarous Greek), a violation of the idiomatic rules of grammar or construction in writing or speaking a language. Quintilian distinguishes solecism from barbarism, the latter word being applied to the erroneous use of single words.

SOLENA'CEANS, *Solenacea*. (Gr. *σωλην*, *a tube*.) The name of a family of Dimiary Bivalve Mollusks, of which the razor shell (*Solen*) is the type; they are distinguished by the great length of the respiratory tubes, whence their name.

SOLENOID. (Gr. *σωλην*, and *ειδος*, *appearance*.) In Electro-Dynamics, a name given by Ampère to a system of small electrical currents, equal and equidistant, and returning into themselves, the planes of which are normals to any given line, whether a straight line or curve, upon which their centres are situated, and which forms the axis of the *solenoid*. (Despretz, *Traité de Physique*, 1836.)

SOLFATA'RA. A volcanic vent emitting sulphur and sulphurous compounds. The term is borrowed from Solfaterra, the celebrated mountain of Naples called by the ancients *Phlegræi Campi*.

SOLFE'GGIO. In Music, the system of arranging the scale by the names ut, re, mi, fa, sol, la, by which musical students are taught to sing, these notes being represented to the eye by lines and spaces, to which the syllables in question are applied. (See art. MUSIC, under which will be found a diagram of the scale under the arrangement in question.)

SOLI'CITOR. The professional designation of persons admitted to practise in the court of Chancery in the conduct of suits, &c., who are styled attorneys in the courts of common law. (*See* ATTORNEY.) The *solicitor-general* is an officer of the crown, who holds by patent, and ranks next to the attorney-general, with whom he is, in fact, associated in the management of the legal business of the crown and public offices. He receives some particular fees on pleadings, and on the enrolment of patents, &c.; but the division of business between him and the attorney-general is chiefly regulated by usage founded on convenience. He is the officer on whom generally devolve the maintenance of the rights of the crown in revenue cases, patent causes, &c. The earliest date at which the name of this officer occurs, so far as is known, is the year 1461. In Scotland, the term solicitor is synonymous with attorney in England. They are inferior to the *writers to the signet*, and practise in the inferior courts.

SO'LID. In Physics, the term *solid* is applied to that condition of matter in which the attractive forces of the molecules are greater than the repulsive, and the molecules consequently cohere with greater or less force. The other states of matter are the *fluid*, in which the attractive and repulsive forces are balanced; and the *gaseous*, in which the repulsive prevail.

SOLID. In Geometry, a magnitude which has three dimensions; length, breadth, and thickness. The boundaries of solids are surfaces. *Regular solids* are those which are terminated by regular and equal planes. They are five in number, viz. the tetraedron, the hexaedron, the octaedron, the dodecaedron, and the icosaedron. *See* PLATONIC BODIES.

SO'LID ANGLE, in Geometry, is an angle made by the meeting of more than two plane angles which are not in the same plane in one point.

SO'LID PROBLEM. In Geometry, a problem which cannot be constructed by the intersections of circles and straight lines, but requires for its geometrical construction the description of one or more conic sections. The algebraic solution of a solid problem leads to a cubic or biquadratic equation. Problems which admit of being constructed by the intersection of two circles, or of a straight line and circle, are called plane problems, and their equations are of the second degree.

SOLIDU'NGULATES, *Solidungula*. (Lat. solidus, *solid*; ungula, *a hoof*.) The name of a tribe of Mammals, including those with only a single hoof on each foot; as the horse, ass, &c.

SOLI'LOQUY. *See* MONOLOGUE.

SO'LIPEDS. Synonymous with *Solidungulates*, which see.

SOLLE'CITO. (It. *afflicted*.) In Music, a term denoting that the movement to which it is affixed is to be performed in a mournful manner. It also means that the music is to be performed carefully.

SO'LO. (It. *alone*.) In Music, a movement, or part of a movement, in which only one voice or instrument is employed.

SO'LSTICE. (Lat. solstitium.) The time at which the sun is at its greatest distance from the equator, and when its diurnal motion in declination ceases. This happens at midsummer and midwinter; or when the sun arrives at the tropic of Cancer and the tropic of Capricorn.

SOLSTI'TIAL POINTS, are those points of the ecliptic at which the sun arrives at the time of the solstices. They are the first points of Cancer and Capricorn.

SOLU'TION. (Lat. solvere, *to untie*.) In Mathematics, the construction of a proposed problem, or the expression of its conditions by an equation which gives the value of the unknown quantity.

SO'MMITE. A mineralogical name of the *nephelin* of Somma and Vesuvius. *See* NEPHELINE.

SOMNA'MBULISM. (Lat. somno ambulare, *to walk in one's sleep*.) This is a species of dreaming, in which the bodily as well as the mental functions are affected. There are many remarkable cases of this kind on record, some of which would appear perfectly incredible, were they not attested not only by creditable, but by competent and scientific witnesses. Somnambulism has been defined, as "a state in which the mind retains its power over the limbs, but possesses no influence over its own thoughts, and scarcely any over the body, excepting those particular members of it which are employed in walking." Dr. Abercromby, in his excellent *Inquiries concerning the Intellectual Powers and the Investigation of Truth*, observes, in regard to this singular affection, that although the mind is fixed upon its own impressions as in ordinary dreaming, the bodily organs are more under the control of the will; so that the individual acts under the influence of his erroneous conceptions, and holds conversation in regard to them. He is also, to a certain degree, susceptible of impressions from without, through his organs of sense; not, however, so as to correct his erroneous impressions, but rather to be mixed up with them. Dr. Abercromby observes, that the first degree of somnambulism generally shows itself by a propensity to talk during sleep; the person giving a full and connected account of what passes before him in dreams, and often revealing his own secrets or those of his friends. Walking during sleep is the next degree, and that from which the affection derives its name. He gets out of bed, often dresses himself, and goes out of doors, walks frequently over very dangerous places in safety; sometimes he gets out of a window, walks along a parapet, gets to the roof of the house, and returns through similar risks to his apartment. On awaking in the morning he is either utterly unconscious of having stirred during the night, or remembers it as a mere dream. These cases are comparatively common; but sometimes the transactions of the somnambulist are carried much further: he will mount his horse and ride, or go to his usual occupations, such as threshing, saddle-making, playing on musical instruments, composing verses, and so forth.

Although somnambulists are generally insensible to any thing that is said to them, they are sometimes capable of holding conversation, especially in those cases where the affection occurs, as it sometimes does, in the daytime. In these attacks the individuals are generally unconscious of external impressions, or at all events extremely confused in their notions of external things. They frequently speak intelligibly, but in reference to the impressions which are present in their own minds. They sometimes repeat poetry, and other matters of which they were supposed to be perfectly ignorant; or they hold conversations with imaginary beings, or relate circumstances which were supposed to have been entirely unnoticed or forgotten. Some have been known to sing in a style superior to any thing to which they could attain when awake; and there are, says Dr. Abercromby, some well-authenticated instances of persons in this condition expressing themselves correctly in languages with which they were imperfectly acquainted.

For the details of individual cases of this extraordinary disorder, we must refer to Dr. Abercromby's instructive volume already quoted, and the authorities therein cited. It is impossible to give any explanation of the extraordinary condition of the faculties which such cases exemplify, or to point out any general plan of treatment applicable to them.

The more ordinary cases of somnambulism are sometimes cured by tying the patient to some part of the bed, or by securing the doors and windows; so that after ineffectual attempts to make his escape he is induced to return to bed, and remains quiet. The state of the stomach and bowels, and of the nervous system, requires careful examination and proper treatment: in some cases intestinal worms appear to have been connected with nocturnal disturbances bearing a close analogy to somnambulism, and which have disappeared after the successful operation of vermifuge remedies.

SO'MNUS, in Classical Mythology, the poetical god of sleep, is the son of Erebus and Nox, or of Nox alone. He dwells with his brother Death in a palace at the

western extremity of the earth. Homer makes Juno seek him in the isle of Lemnos, whither he had repaired for love of the nymph Pasithea. Ovid makes him dwell in a cavern among the Scythians or Cimmerians; Statius in Æthiopia.

SONA'TA. (It. sonare, *to sound.*) In Music, a composition executed wholly by instruments. It is generally a free composition for exhibiting the composer's powers, without confining him within the rigid rules of counterpoint, or measure.

SO'NNET. (It. sonetto.) In Poetry, a short composition of fourteen or fifteen lines, deca or endecasyllabic, rhymed according to an intricate but not always precisely similar arrangement. It is the oldest form in which the Italian language was used; but was, at a still earlier period, employed, although not commonly, by the Provençal poets. In Italy, Dante and the Tuscan poets his contemporaries brought the sonnet into public estimation, about the beginning of the 14th century; but by them it was invariably employed as the vehicle of thoughts wrapped in very obscure language, and probably of a symbolical nature, though generally, in their outward signification, breathing the spirit of romantic and chivalrous love. By Petrarch, in the course of the same century, the sonnet was carried to perfection in point of form and polish; although applied by him, as it had been by his predecessors, almost exclusively to the subject of his figurative and mystical passion. Since the time of Petrarch the sonnet has been a favourite form of composition in Italy, especially for the purposes of occasional poetry. In France it has had little success; or rather the French sonnet is a different poem, less regular in its construction than the Italian. In Germany and England the comparative poverty in rhymes of their respective languages has rendered it unusual; but Milton has given to it a dignity peculiarly his own, together with much of the melody and tenderness which characterize his Italian models. The proper sonnet is divided into two quatrains, with four lines and two rhymes each, and two terzines, each with three lines and a single rhyme. Pieces of a similar metrical structure in octo-syllabic lines are termed by the Italians Anacreontic sonnets. It is sometimes said that there is " hardly an educated Italian who has not composed a sonnet."

SO'PHIST. (Gr. σοφιστης; from σοφος, *wise.*) A Greek word, originally signifying a person of talent and accomplishments. It was afterwards restricted to a bad sense, and applied to a class of men who arose in Greece in the fifth century B.C., and taught the youth in the principal cities various arts and acquirements for hire. It has hence come to be the general designation of all such as cultivate any branch of science or philosophy with a view to outward advantages, careless of the truth of what they advance, except in so far as it may contribute to those purposes. The first Greek who assumed the name of *Sophist* was Protagoras, a native of Abdera, who flourished about the year 440 B.C., and obtained numerous pupils and auditors, especially in Athens. Of those who followed the same occupation the most celebrated were Hippias of Elis, Gorgias of Leontium, Prodicus of Ceos, and Euthydemus of Chios, with his brother Dionysiodorus. None of the writings of these men have survived; but we have abundant notices in the writings of their contemporaries, especially Plato, Xenophon, and Aristophanes, of the nature and tendency of the doctrines and principles which they communicated to the youth of Greece. Of the truth of these accounts the Grecian history of the latter part of the fifth century furnishes us with a melancholy testimony. It is, indeed, to the changes which had begun to take place in the internal and external relations of the Greek states, that the prevalence and success of the Sophists are mainly to be attributed. The changes in the distribution of property which these revolutions rendered necessary excited the passions and gave scope to the energies of the young and enterprising; at the same time that the political alterations tended to shake men's confidence in those moral principles which among the Greeks were intimately bound up with their civil institutions. We accordingly find the leading feature of the sophistic doctrine to be a dislike to every thing fixed and necessary, in ethics as well as philosophy. Prescription was represented as the sole source of moral distinctions, which must consequently vary with the character and institutions of the people. The *useful* was held to be the only mark by which one opinion could be distinguished from another. An absolute standard of truth is as absurd a notion in speculation as an absolute standard of morals in practice: that only is true which seems so to the individual, and just as long as it so seems. " Man is the measure of all things." These and similar doctrines they maintained with great subtlety and acuteness, and found numerous disciples among those who were well prepared for the admission of tenets which swept away at once all the remnants of those prejudices which might still interpose a barrier between their passions and their gratification. Considered as a link in the chain of philosophical development, the Sophists were doubtless the involuntary cause of the greater depth and soundness of the subsequent Grecian philosophy. The success which they had found in demolishing the systems of their predecessors proved the necessity of laying the foundations of human knowledge deeper than heretofore had been done; and it is thus to the Sophists that we may attribute the more critical and cautious spirit which distinguishes the doctrines of Plato and Aristotle from those of Heraclitus or Parmenides. (See Ritter, *Hist. of Ancient Philosophy*, book vi.; *Mem. de l'Ac. des Inscr.* vol. xiii. xxxii.; *Ed. Review*, vol. xxxiv.)

SOPORI'FICS. (Lat. sopor, *sleep.*) Medicines which induce sleep.

SO'PRA. (It. *above.*) In Music, a term frequently used for description; as *nella parte di sopra*, in the higher or upper part; *di sopra*, above; *contrapunto sopra il sogetto*, counterpoint above the subject, &c.

SOPRA'NO. (It. sopra.) The upper or treble part in composition.

SO'RBIC ACID. The acid of the berries of the *Sorbus ancuparia*, or mountain ash. It is identical with the *malic acid.*

SORBO'NNE. A college at Paris for the study of theology; so called from the village of Sorbonne, in Champagne, where its founder, a priest named Robert, was born about the beginning of the 13th century. He made a provision for the instruction of sixteen poor clerks in theology; and his college is said to be the first example of what was afterwards the common character of all the English colleges, the institution of a cænobium for regular clergy. The college of the Sorbonne was adorned with various new edifices and enriched with a library by Cardinal Richelieu, in 1629. His monument in the church is considered a chef-d'œuvre of French art. (See Mosheim, *Eccl. Hist.* vol. iii. transl. 1790, p. 53. &c.) This great college of theology exercised a high influence in ecclesiastical affairs, and on the public mind, especially in the 16th and 17th centuries; insomuch that the sceptical wits of the 18th usually employ the name as synonymous with the spirit of bigotry itself. Its proverbial celebrity for acuteness in theological disquisition is attested by the lines of our own Butler:—

For he a rope of sand could twist
As firm as learned Sorbonist.

SO'RCERER. (Lat. sortitor, from sors, *a lot;* whence *sorcery.*) Properly one who practises sortilege, or divination by lot (which see); but, in the ordinary language of the middle ages, one exercising magical powers (*see* MAGIC), especially by the aid of evil spirits. The *sorcerer* of the middle ages was, generally speaking, a personage of distinction, while the *witch* was degraded and loathsome. The species of sorcery which is still practised in the East, especially in Egypt, by means of the magic mirror, has recently attracted much attention. The most complete account of it will be found in *Lane's Modern Egypt.*

SORDINI. In Music. *See* CON SORDINI.

SORE'DIA. In Botany, heaps of powdery bodies found in lichens lying upon any part of the surface of the thallus.

SO'REX. (Lat. sorex, *a field-mouse.*) A Linnæan genus of the order *Bestiæ*, now forming an extensive tribe of Insectivorous Ferines (*Carnassiers*) in the system of Cuvier, and subdivided into different genera. The original generic term is confined to the shrews, or shrew-mice, which are the type of the family (*Soricidæ*), and are characterized by having the two superior middle incisors curved and indented at the base, the two inferior incisors prolonged and procumbent. Behind the upper pair of incisors there are five little conical teeth on each side, and two similar teeth behind the lower pair of incisors: the molars, which are beset with sharp cusps, are four on each side above, and three below. The true shrews are further characterized by lateral, and sometimes anal and femoral scent-glands. The principal genera, now distinct, which would have ranked with the Linnæan *Sorex*, are *Myogalea, Condylura, Tupaia, Gymnura, Macroscelis, Cladobates, Solenodon, Crossopus, Crocidura.* Of these *Gymnura* belongs rather to the family of hedgehogs, and *Condylura* to that of the moles.

SORI. (Gr. σωρος, *a heap.*) The small heaps of reproductive granules found growing upon the fronds of Polypodiaceous ferns.

SORI'TES. (Gr. σωρος, *a heap.*) In Logic, an abridged form of stating a series of syllogisms, of which the conclusion of each is a premiss of the succeeding one: *e. g.* $A = B$, $B = C$, $C = D$; therefore $A = D$. This is a sorites, consisting of two distinct syllogisms, which, drawn out at length, would stand thus: $A = B$, $B = C$; therefore $A = C$; and $A = C$, $C = D$; therefore $A = D$.

SO'RREL, SALT OF. Binoxalate of potash.

SO'RTES HOME'RICÆ, VIRGILIANÆ, SANCTORUM, &c. A species of sortilege or divination was practised in antiquity by opening at random a favourite author, and applying the first passage which met the eye to the circumstances of the inquirer as an oracular answer: termed by the Greeks στοιχειομαντεια. They

chiefly used Homer for this purpose. Thus Socrates when in prison, hearing the line of Homer repeated,

ἠματι κεν τριτατῳ, Φθιην ἐριβωλον ἱκοιμην,

interpreted it to foretel his own death within three days, by a play on the word Phthia. Among the Romans, Virgil was chiefly consulted, and many celebrated instances are preserved. Adrian, when desirous to know on what terms he stood with his patron, the emperor Trajan, consulting the *Æneid,* opened at the verses respecting Numa, "Nosco crines incanaque menta Regis Romani," &c.; and thence drew the augury of his future elevation to the empire. Alexander Severus, according to Lampridius, obtained a similar presage from the lines "Excudant alii spirantia mollius æra," &c. The anecdote of the ominous passages discovered by Charles I. and Lord Faulkland, when opening Virgil in the public library at Oxford, is well known (see *Welwood's Memoirs*). In Christian times, the Sortes Sanctorum came in fashion. They were obtained by consulting the inspired writings in the manner before described; sometimes, also, the inquirer went into a church while service was performing, and drew a prognostic from the first words he heard. In this way, St. Anthony was directed to adopt a life of solitary devotion. These practices became the occasion of much superstition. They are condemned by St. Augustine in his Epistle to Januarius; but are nevertheless continually mentioned, with evident credulity and approbation, by early ecclesiastical writers. Gregory of Tours, among other similar stories, has one of the French prince Meroveus, which shows the ceremonious manner in which they were sometimes performed. That prince having fled to the basilica of St. Martin, placed separately on the saint's tomb the Psalms, the book of Kings, and the Gospels, and, spending three days and nights at the tomb in fasting and devotions, on the fourth day he opened these sacred books; from each of which he drew a discouraging prediction. Elections to the episcopal offices, and other solemn proceedings, seem to have been sometimes decided in the same manner in the dark ages. And after this abuse had ceased, it was long a common practice, on the consecration of a bishop, after the book of the Gospels had been laid on his head, to consider the first verse which offered itself as a prognostic of his behaviour and the fortunes of his episcopacy. Thus the death of Albert, bishop of Liege, was intimated by the ominous occurrence of the passage respecting the execution of John the Baptist; and that prelate was accordingly put to death by Henry VI. The Sortes Sanctorum had been, however, forbidden by the council of Vannes in the 5th century, and that anathema was repeated on many later occasions, in which the consulting of the scriptures is classed with other profane and magical modes of divination. There is an essay on Sortes in the *Mem. de l'Ac. des Inscr.* vol. xix. *See* STICHOMANCY.

SORTIE, or SALLY. In Military language, a term borrowed from the French to signify a sudden attack made by the inhabitants of a besieged city upon the besiegers.

SO'RTILEGE. (Lat. sors, *lot;* lego, *I collect.*) Divination by lots. A very ancient mode of exploring future events, and which has been supposed by superstitious persons in modern times to derive countenance from various incidents in sacred history, especially the choice of St. Matthias by lot to the place of an apostle (Acts, i. 26.). The different modes in which sortilege has been practised will be found detailed under that word, in a learned article in the *Enc. Metropolitana;* and *see* SORTES.

SOSPI'RO. (It. *a sigh.*) In Music, the same as Rest, which see.

SOSTEN'UTO. (It. *sustained.*) In Music, a term which, affixed to a note, indicates that it is to be held out in an equal and steady manner.

SOTHIC YEAR. In Chronology, the Egyptian year of 365 days (said to have been introduced into Greece by Orpheus) was so called from Sothis, the Dog-star, at whose heliacal rising it was supposed to commence. (*Bryant's Ancient Mythology*, vol. iv.)

SO'TTO. (It. *below.*) In Music, a term frequently used for description; as *sotto il sogetto*, below the subject; *nella parte di sotto*, in a lower part.

SOUND. (Fr. son.) The sensation produced by the vibrations of the air or other medium with which the organ of hearing is in contact. The doctrine of sound is usually treated under the head *acoustics;* a branch of physics which has for its object the determination of the laws by which the peculiar motions which give rise to the sensation of sound are produced in bodies and conveyed to our ears, and the manner in which they act on those organs; in other words, to explain the origin, propagation, and perception of sound.

Although, strictly speaking, sound is only a sensation excited in the auditory organ, yet in treating of the subject it is usual to transfer the name from the sensation to the motion which gives rise to it. We shall therefore speak of sound as if it proceeded from the *sounding* body; and speak of a body as sounding when its particles are in that state of vibration which is requisite for making an impression on the ear, either immediately or through the medium of some other elastic substance.

Phenomena of Sound. — In order that a body may produce sound, it is necessary that its particles be in a state of rapid vibration; and in order that these vibrations may be communicated to the auditory organ, it is necessary that air or some elastic medium be interposed between the vibrating body and the ear. Hauksbee having suspended a bell under the receiver of an air-pump, found the sound become feebler in proportion as the air was removed, and again become stronger as the air was readmitted, and also that when the bell was suspended in a vessel full of air, and placed under the receiver, no sound was transmitted when the air between the vessel and the receiver was exhausted. This experiment has been repeated by Biot, with a more perfect apparatus, and with every attention to the circumstances by which it is influenced; and it was found that when the exhaustion was complete no sound was perceptible, even when the ear was brought close to the receiver. Hence it appears that sound cannot be communicated through a perfectly void space. But although air is the medium through which sound is usually communicated, this only happens because it is the medium with which the ear is usually in contact; and many other media are found by experiment to perform the office even more perfectly. Franklin having plunged his head under water, caused a person to strike two stones together beneath the surface, and at more than half a mile distance heard the blows distinctly. Colladon by plunging a few feet into the water a thin tin cylinder closed at the lower end, but having the upper open to the air, was enabled to hear the sound of a bell struck under water at the distance of 2000, 6000, and even 12,000 mètres (about 9 miles); namely, across the whole breadth of the lake of Geneva, from Rolle to Thonon. The conducting power of wood along the fibres is very remarkable. Let a person bring his ear close to the end of a fir deal, however long, and he will distinctly hear the slightest scratch made with the point of a pin at the other end, although the sound may be so feeble as to be inaudible to the person who makes it. Miners at work in one shaft often hear the sound of the pickaxe in another through the solid rock; and in general all solids tolerably compact are good conductors of sound.

Sounds are propagated to great distances and with remarkable distinctness over a surface of water, or ice, or frozen snow. In the account of Parry's third polar expedition, it is stated that two persons could hold a conversation across the harbour of Port Bowen, a distance of 6696 feet, or about a mile and a quarter. Instances are also recorded of sounds propagated to almost incredible distances over land. Derham relates the following: — Guns fired at Carlscroom were heard across the southern extremity of Sweden, as far as Denmark, a distance of 120 miles. Dr. Hearn, a Swedish physician, relates that he heard guns fired at Stockholm at the distance of 30 Swedish or 180 English miles: the cannonade of a sea-fight between the English and Dutch, in 1672, was heard across England as far as Shrewsbury, and even in Wales, a distance of upwards of 200 miles from the scene of action.

The diminution of the intensity of sound in rarefied air is rendered manifest not only by experiments with the air-pump, but also by the phenomena observed at great altitudes in the atmosphere. Saussure relates, that at the summit of Mount Blanc the report of a pistol was not louder than that of a small cracker in the plain below; and Gay Lussac, having ascended in a balloon to an altitude of nearly 23,000 feet, far above the clouds and away from all solid substances, observed the intensity of the sound of his voice to be greatly enfeebled.

It is matter of familiar observation that sounds are not propagated through the air instantaneously, but occupy a sensible portion of time in passing from one station to another, greater in proportion as the stations are more remote. The blow of a hammer on an anvil is not heard by an observer at some distance, until a sensible time has elapsed after the hammer has been seen to descend; and the flash of a gun fired a mile off is seen several seconds before the report is heard. But all sounds, whatever be their loudness or pitch, are propagated with the same velocity through the same medium. In listening to the music of a concert, the sounds follow each other in the same order and at the same intervals; and the same measure and harmony are perceived, at whatever distance the hearer may be from the orchestra. Biot caused several airs to be played on a flute at the end of a pipe 3120 feet long, which were distinctly heard at the other end without the slightest derangement in the order or intervals of sequence of the notes. This could not have been the case if there had been the smallest difference in the velocity of their propagation.

Numerous experiments have been made for the purpose of determining the actual velocity of sound through the

atmosphere. The usual mode of making the experiment is to observe the interval between the flash and the report of a cannon fired at a known distance. In this manner the Florentine academicians, in 1660, found the velocity to be 1148 English feet per second. These experiments were repeated in France in 1698, by Cassini, Huygens, Picard, and Roemer, who found 1172 feet; and Flamsteed and Halley at the royal observatory of Greenwich, from experiments made at the distance of 3 miles, found the velocity to be 1142 feet per second. This result was confirmed by Derham (*Phil. Trans.* 1708), who found the same velocity by a mean of observations made at more remote distances. In 1737, the Academy of Sciences of Paris directed farther experiments to be made by Cassini de Thury, Maraldi, and Lacaille; and on this occasion the experiments were for the first time made so as to eliminate the effect of the wind by reciprocal observations; that is to say, by firing cannon at both ends of the line, either simultaneously or at short intervals. They also appear to have been the first who observed and recorded the temperature of the air at the time of the experiment; a very essential element, as will presently be seen. The result at which they arrived gave the velocity equal to 1106 English feet per second, at a temperature between 4° and 6° of Reaumur, or between 41° and 44½° of Fahrenheit. When the proper reduction is made for temperature, this agrees very nearly with the best modern observations.

Various other experiments were made in different countries in the course of the last century (viz. by Bianconi in Italy, in 1740; by Condamine at Quito and Cayenne, in 1740 and 1744; by Mayer in 1778, and Muller in 1791, in Germany; by Espinosa and Bauza in 1794, at Chili); but as the observers had not the means of determining minute intervals of time with the precision which has been attained in more recent experiments, and besides neglected some circumstances which influence the result, it is unnecessary to state the details.

Since the beginning of the present century, the velocity of sound has been measured in various countries; in Germany, by Benzenberg at Dusseldorf in 1809, and by Myrbach and Stamfer at Saltzburg in 1822; in France, by directions of the Bureau des Longitudes, in 1822; in Holland, by Moll, Vanbeek, and Kuytenbrewer, in 1823; in England, by Dr. O. Gregory at Woolwich, in 1824; in the East Indies, by Mr. Goldingham, in 1821; and at Port Bowen, in the polar regions, by Parry and Foster, in 1825. The results of these measurements, when reduced to the same temperature, agree very nearly with one another; but the experiments made in France and Holland are by far the most circumstantial and satisfactory. In the French experiments, two stations in the neighbourhood of Paris were chosen, Villejuif and Montlehéry; and the signals were made by firing a gun from each station alternately, at an interval of five minutes. The observers at Villejuif were Prony, Arago, and Mathieu; and at Montlehéry, Humboldt, Gay Lussac, and Bouvard. The observations commenced at 11 o'clock on the nights of the 21st and 22d of June, and were continued on both nights during two hours; but in many instances the reports were not heard, at least by all the observers. The intervals between the flashes and reports were observed by means of stop watches of a peculiar construction, which permitted the seconds to be divided and noted. The mean of all the observations gave 54·6 seconds for the time which sound took to travel from the one station to the other. The distance between the stations was afterwards determined by Arago, and found to be 9549·6 toises (11⅓ miles); whence the velocity is 174·9 toises, or 340·88 metres in a second. But this is the velocity belonging to the mean temperature, which was 16° centigrade (61° Fahrenheit), and corresponds to a velocity of 331·12 metres (1086·1 English feet), at the temperature of freezing water. The details of these experiments are given in the *Connaissance des Temps* for 1825.

In the Dutch experiments, a clock with a conical pendulum was used, which gave the means of determining the time to the hundredth of a second by suddenly arresting the motion of the index without stopping the clock. As in the French experiments, guns were fired from each extremity of the line; but instead of being fired alternately, they were in the present case fired simultaneously, so that any error that might be feared from a variation in the state of the atmosphere or the wind was entirely eliminated. The state of the hygrometer was also observed. The interval between the stations was 57839 feet (nearly 11 miles); and the mean of all the experiments reduced to the freezing temperature, and for dry air, gave for the velocity of sound 1089·42 feet in a second. The details are given in the *Phil. Trans.* for 1824.

Dr. Gregory's observations are given in the *Transactions of the Cambridge Phil. Soc.* for 1824. The signals were not reciprocal; but the velocity of the wind was measured by an anemometer, and allowed for. The distances were also very much smaller (varying from 2700 to 13460 feet); nevertheless the results agree very well with those above mentioned. Mr. Goldingham's experiments at Madras are much less certain; his method consisted in taking a mean of the velocities observed daily in calm weather, during a long time, by the firing of the morning and evening guns at two stations visible from Madras, and a mean of all the observed temperatures for the reduction. (*Phil. Trans.* for 1823.) Benzenberg's experiments are given in *Gilbert's Annalen*, new series, v. 383.; and those of General Myrbach in the *Jahrbuch des Polytek. Instituts zu Wien*, vol. vii. The experiments of Parry and Foster are given in detail in *Parry's Journal of a Third Voyage, &c.* The mean result deduced by Dr. Moll (*Phil. Trans.* 1828) gives the velocity equal to 1035·2 feet in a second, at the temperature of 17·7° Fahr., which corresponds to 1092 feet at 32°; but the circumstances were unfavourable. The following table exhibits in one view the results of the principal experiments now described. The numbers are taken from a more extended table given by Sir John Herschel in the *Ency. Metropolitana*, art. "Sound;" to which admirable treatise we refer the student for information on all points connected with this important subject.

Date of Observation.	Observer.	Distance of Stations in Feet.	Velocity per Second in English Feet at the temperature of freezing water.
1809.	Benzenberg -	29764	1093
1821.	Goldinham - -	29547 13932	1086·7
1822.	Myrbach - -	32615	1092·1
1822.	Arago, Mathieu, &c.	61064	1086·1
1823.	Moll, Vanbeek, &c. -	57839	1089·42
1823.	Dr. Gregory - -	from 2700 to 13460	1088·05
		Mean of the whole	1089·2

These results agree remarkably well with each other, the greatest deviation from the mean being less than 4 feet, and the mean of the whole being almost identical with the determination of Moll and Vanbeek. "We may, therefore," says Sir John Herschel, "adopt 1090 feet without hesitation (as a whole number), as no doubt within a yard of the truth, and probably within a foot." This is the velocity with which sound travels in dry air, at the temperature of freezing water. But the velocity increases with the temperature (as will be shown presently), at the rate of 1·14 foot, very nearly, for each degree of Fahrenheit's scale. Hence at the temperature of 62° (the standard temperature of the British metrical system), the velocity is 1124½ feet. We may therefore assume the velocity of sound at this standard temperature, as determined by the best experiments, to be 1125 feet per second.

Theory of Sound. — It has already been stated that sound is produced by the vibrations of the molecules of a solid body communicated to the atmosphere or other elastic medium, and conveyed by it to the ear. The physical theory of sound, therefore, resolves itself into two parts: 1st, the state or condition of the vibrating body; and 2d, the mode in which this mechanical action is propagated through the medium to the organ of sense.

State of Sonorous Body. — In order that a body may give out sound, its particles must be put into a state of rapid vibration. If the frequency of the vibrations is under a certain limit, no sound will be produced; above that limiting velocity of vibration, sound is produced; and experience shows that the quality of the sound becomes more and more acute as the vibrations are more rapid, until a second limit of velocity is attained, beyond which the human ear is affected with no sensation of sound. To prove this experimentally, let a thin plate of tempered steel have one of its ends firmly fixed in a vice, and let the other end be drawn a little aside from the position of rest. As soon as the force by which the plate is bent is removed, the plate commences a series of vibrations, which become smaller and smaller until the position of rest is again attained. But the vibrations are all performed in equal times; and if sufficient length is given to the plate, they take place so slowly as to admit of being accurately counted. On shortening the plate, they become more rapid; and long before they attain that degree of rapidity which is necessary for the production of sound, it becomes impossible to count them directly; but it is demonstrable that when a plate of metal of equal thickness throughout is made to vibrate in the manner now supposed, the time of a vibration is directly proportional to the square of the length of the plate, and consequently the number of vibrations in a given time is inversely as this square; so that if the number in a second corresponding to any length of the plate has been counted, the number corresponding to any other given length can be readily computed. In this manner it has been found that a metallic plate begins to sound when the number of vibrations in a second is 32; and at this velocity of vibration, the sound

which it gives is of the same pitch as that of an organ pipe 32 feet in length, open at both ends. (By *vibration*, we here understand the passage of the plate from the extreme excursion on one side of the position of rest to the opposite, and not the going and returning, or complete vibration.)

This appears to be the minimum velocity of vibration capable of producing sound. The other limit, or maximum velocity at which sound ceases to be appreciable, is not so easily determined. Until recently it has been usual to fix it at 8200 vibrations in a second; but M. Savart has discovered that by increasing the amplitude of the vibrations, acute sounds may be distinguished at a velocity of 24,000 vibrations in a second; and it is possible that the limit may still be considerably above this number. By means of an ingenious apparatus, Savart has succeeded in determining the number of vibrations producing a sound of any given pitch with great exactness.

Several other means exist of determining the absolute number of vibrations in a given time, corresponding to different musical sounds; of which one of the most certain, and most frequently had recourse to, depends on the mathematical relation subsisting between the time of vibration, the length of the cord, and the tension of vibrating cords. Let n denote the number of vibrations in a second, g the accelerating force of gravity (32 feet in a second), l the length of the cord, w its weight, t its tension (or the weight by which it is stretched); then a formula equivalent to the following was demonstrated by Brook Taylor (*Methodus Incrementorum*, p. 93.): —

$$n = \sqrt{\frac{g\,t}{l\,w}}.$$

In this formula g is known, and t, l, and w are measurable quantities, so that n is completely determined; but a more convenient expression is obtained by substituting the diameter and density of the cord for its weight. Let r be the radius of the cord, δ the density of its matter, and π the ratio of the circumference to the diameter, or $\pi = 3{\cdot}14159$; then $w = \pi\,\delta\,g\,r^2\,l$, and the above formula becomes

$$n = \frac{1}{r\,l}\sqrt{\left(\frac{t}{\pi\,\delta}\right)}.$$

From this it results that the number of vibrations in a second is proportional directly to the square root of the tension of the cord, and inversely to its length, to its thickness or diameter, and to the square root of its density.

In the *Memoirs of the Berlin Academy* for 1822 and 1823, are given the results of a great number of experiments made in this manner by M. Fischer, for determining the velocity of vibration corresponding to different musical sounds. The rapidity of vibration giving the diapasons (that is, the concert pitches) of various orchestras at Berlin was found to be as follows: — Berlin Theatre 437·32, Great French Opera 431·34, Feydeau 427·61, Italian Theatre 424·17 vibrations per second. The reach of the voice of a man usually extends from sol_1 to fa_3 in the musical gamut; and that of a woman from re_3 to la_4. Taking the diapason of the Italian Opera as the standard, the rapidity of vibration corresponding to these several notes is as follows: — Sol_1 190·8, fa_3 678·4, re_3 572·4, la_4 1606 vibrations per second. But the voices of some singers reach much higher than la_4, and consequently the rapidity of vibration with respect to them will be higher in proportion.

Some of the most acute sounds, or highest tones which the ear can distinguish, are given by the wings of insects; and they correspond to the astonishing rapidity of 12000 or 15000 vibrations in a second. When we reflect how extremely probable it is that the tympanum of the ear vibrates in unison with the sounds that affect it, we cannot fail to be struck with admiration of the wonderfully delicate organization of a substance which possesses the power of adapting itself to all velocities of vibration, from 32 times in a second up to 24,000, the number found by Savart to be sensible. The limits, however, at which very acute sounds cease to be audible appear to vary considerably in respect of different individuals, some being altogether insensible to sounds which painfully affect others. (See a very interesting paper on sounds inaudible to certain ears by Dr. Wollaston in the *Phil. Trans.* for 1820.)

The mathematical problem, to determine the vibrations of a stretched cord, is one of very great difficulty. After exercising the talents of Dr. Brook Taylor, D'Alembert, Euler, Daniel Bernoulli, and others, it was completely solved by Lagrange, in the first volume of the *Turin Miscellanies*, and all the deductions from theory are found to be confirmed by experiment. The subject of the vibrations of solids has been recently examined experimentally by M. Savart, and the results given in a series of most important memoirs communicated to the French Academy of Sciences, and printed in different volumes of the *Annales de Chimie*. *See* VIBRATION.

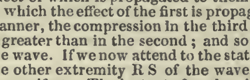
Propagation of Sound. — In order to convey an idea of the manner in which the vibratory motions of a sonorous body are communicated to the atmosphere or other elastic medium, let us conceive a tube, T T′, of an indefinite

(1.)

length, and open at both ends, to be filled with air of a uniform temperature and density throughout. Let us also suppose a piston, P Q, which closely fits the tube, and is moveable within it along the direction of the axis, to be propelled suddenly from the position P Q to R S; and to simplify the consideration, let the distance P R be supposed one foot, and the time in which the piston moves from P Q to R S to be one second. Now, assuming the air within the tube to have been in a state of rest before the piston began to move, let us consider what will be its state at the instant when the piston arrives at R S. If the air in the tube were acted upon as a perfectly hard body, any motion communicated to the particles at one extremity would be instantaneously conveyed to the other; and when the piston arrived at R S a quantity of air, equal to that which was contained between P Q and R S, would be expelled at T′, and all the particles within the tube would come to rest at the same time with the piston. But in consequence of the compressibility of the air the motion is not communicated to the distant particles instantaneously, but only after a sensible interval of time; and we may conceive the tube to be so long that when the piston has arrived at R S no air has yet been propelled from the tube at T′. In fact, the disturbance or compression of the particles, which takes place at the instant the piston begins to move, is propagated along the tube with a certain determinate velocity, depending on the elasticity of the air, and when the piston reaches R S will only have reached to a certain determinate distance. Let A B be the section of the tube which the first compression has reached at the instant the piston comes to R S; then, at the instant of time on which we have to fix our attention, the column of air between R S and A B will be in a state of compression, and between A B and the end of the tube at T′ it will still remain in its natural state. The column of air between R S and A B, which is thus modified by the stroke of the piston, is called a *wave* or *undulation*, and R A is the *length* of the wave.

On attending to the state of the molecules in the column R A, it will readily be seen that they are not subjected to the same degree of compression through its whole length. Conceive the wave to be divided into a very great number of thin layers by sections parallel to R S or A B, and that the piston, in passing from the position P Q to R S, has produced the effect, not instantaneously, but by a great number of successive small impulses. At the instant the piston comes to R S the disturbance has by hypothesis been propagated only to A B, and consequently the particles in the infinitely thin layer next to A B have suffered only the slightest degree of compression, or that caused by the first impulse of the piston. In the second layer next to A B the molecules of air are in a state of greater compression; inasmuch as they have sustained not only the compression due to the first impulse of the piston, but also that which is due to the second, the effect of which is propagated to them at the same instant at which the effect of the first is propagated to A B. In like manner, the compression in the third layer preceding A B is greater than in the second; and so on to the middle of the wave. If we now attend to the state of the molecules at the other extremity R S of the wave, a similar effect will be manifest. The instant after the piston stops, the layer next to R S has communicated all its velocity to the one preceding it, and remains at rest; or, at the moment of the arrival of the piston at R S, sustains only the compression due to the last impulse. The next layer in succession sustains the compression due to two impulses of the piston, — the last, and last but one. By following out this mode of reasoning, it will readily appear that the particles in the state of greatest compression are those towards the middle of the wave; and that if upon S B, as an axis (fig. 2.), we raise a great number of perpendiculars, *a a*, *b b*, *c c*, &c., each proportional to the compression at the corresponding point of the column, the curve drawn through the summits of these perpendiculars will represent the law of compression; and hence is of the form represented in the annexed diagram, the parts on each side of the middle ordinate *b b* being perfectly symmetrical.

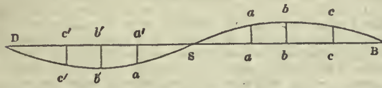
(2.)



If we now attend to the motions developed on the other side of the piston, it will be easily seen that similar phenomena must take place; but in a reverse order, inasmuch

as the air within the tube on that side must be rarefied, instead of being compressed by the motion of the piston from P Q to R S. Let C D (fig. 1.) be a section of the tube, so that the column C R is equal to R A; then, as the velocity of propagation depends only on the nature of the medium, it is obvious that at the instant in which the piston arrives at R S the disturbance of the molecules will only have extended to C D. The whole column between C D and R S will be rarefied by the withdrawal of the piston of air between P Q and R S; but the rarefaction will be greatest at the middle of the column, for the very same reasons that the condensation is greatest at the middle of the column between R S and A B. If, therefore, we represent the rarefaction by

(3.)



negative ordinates, $a' a'$, $b' b'$, $c' c'$, &c. (fig. 3.), the state of the column of air between A B and C D (and this is all which is modified by the passage of the piston from P Q to R S) will be represented by the double curve D b' S b B, the small part between P Q and R S being neglected as insensible. There are thus two distinct waves or undulations caused by the motion of the piston: the wave S B *before* the piston is called the *condensed wave*, and S D *behind* the piston is called the *rarefied wave*. But some writers on acoustics consider both these as belonging to the same wave; and therefore understand by the term wave the whole mass of particles between C D and A B (fig. 1.) which have been disturbed by the motion of the piston from P Q to R S.

As every thin stratum of air in the tube, by reason of its elasticity, communicates to the stratum before it the impulse which it has received from the one behind it, all the particles will successively be affected in the same manner; and at the end of a second interval, equal to that in which the piston has passed from P to Q, the motion will be communicated over another space equal to R A, or the wave will have moved forward its whole length, retaining always the same form; and, supposing the piston to have in this second interval remained at rest at R S, all the particles in the space R A will have returned to their original state of quiescence.

If, instead of supposing the piston to remain at rest at R S, we suppose it to be drawn back, in the second interval of time, to its original position at P Q, then all the phenomena now described will be repeated in the reverse order; that is to say, the compressed wave will be to the left of the piston, and the rarefied wave to the right; and the state of the particles within the tube, with respect to their compression, as modified by the advanced and subsequent retreat of the piston (the complete vibration), will be represented as under (fig. 4.).

(4.)

We have now only to suppose this forward and backward motion of the piston to be performed with the same rapidity as the vibrations of an elastic plate or stretched cord, and the phenomena now described will give an idea of the mode in which sound is transmitted through the atmosphere.

From this illustration (imperfect as it is) of the nature of the motions communicated to the air by the vibrating body, it is easy to see that the particles of air in the tube do not change their places *inter se*, but acquire a vibratory motion, backwards and forwards, along the length of the tube. It is also obvious that the vibrations of the air through which sound is transmitted must be precisely equal in number to those of the sounding body; and as soon as the vibrations cease those of the air cease likewise. But so long as the body vibrates, or the reciprocal motion of the piston is continued with the same velocity, a continued musical sound will be heard; and this will be precisely the same at whatever part of the tube the ear is situated, all the waves being perfectly similar.

It is also evident that sound is propagated not only in straight lines, like light, but in every possible direction. Air being equally elastic in all directions, each point of a sonorous wave may be regarded as a new centre, from which rays are propagated on all sides. A sound heard from the opposite side of a mountain is not conveyed through the mountain, but through the air in curved or crooked lines along secondary rays.

Sounds differ from one another in three respects,—pitch, intensity, and quality. The pitch, or tone, depends on the length of the wave; or, which comes to the same thing, on the number of vibrations in a given time (for the velocity being constant, the length of the wave multiplied by the number of vibrations in a given time is constant). The gravest tone which the ear can distinguish corresponds to a wave of about thirty-two feet in length, and the most acute to one of about half an inch. Two sounds, however different in loudness or quality, are always in perfect unison when the undulations by which they are conveyed are precisely of the same length. The intensity or loudness does not depend on the length of the wave, but on the degree of compression which the air receives; that is, on the violence of the impulses, or the length of the stroke of the piston in the above illustration. The *quality* of sound (the *timbre* of the French authors) is less easily explained. It probably depends on the greater or less abruptness of the impulses, or of the changes of velocity and density of the strata of air between the two extremities of the wave.

Theoretical Determination of the Velocity of Sound.— The investigation of the velocity of sound through the atmosphere (or any gaseous medium) is based upon this fundamental proposition of dynamics, viz. that the velocity of the pulses in an elastic medium is as the square root of the elasticity divided by the density of the medium. Let $v =$ the velocity, $e =$ the elasticity, $d =$ the density; and the proposition gives $v = \sqrt{(e \div d)}$. Make $g =$ the measure of gravity (386·29 inches per second), $w =$ weight of the unit of volume of air, $h =$ height of the homogeneous atmosphere (*i. e.* of a column of air of the same density throughout, and whose weight exercises on the base a pressure $= e$); we have then $e = h\, w$, $d = w \div g$; and the above equation becomes $v = \sqrt{(g\, h)}$. But this is the velocity which a heavy body acquires by falling in vacuo from a height $= \frac{1}{2} h$; therefore, the velocity with which sound is propagated through the air is the same as that which a heavy body would acquire by falling through half the height of the homogeneous atmosphere. This proposition was given by Newton in the *Principia* (lib. ii. prop. 47.), but from a theory wholly inapplicable. The correct demonstration was first given by Lagrange.

In order to convert this formula into numbers, it is necessary to determine h. Let $b =$ the standard height of mercury in the barometer, and $m =$ the ratio of the density of mercury to the density of atmospheric air under the same pressure; then $h = m\, b$, and the velocity becomes $v = \sqrt{(g\, m\, b)}$. At the temperature of freezing water (32° Fahr.), and under a barometric pressure of 29·927 inches, the value of m is found by experiment to be 10,466. But we have also $g = 386{\cdot}29$ inches; whence at that temperature $v = 10{,}998$ inches, or 916 feet.

Since the velocity, as above stated, is proportional to the square root of the elasticity divided by the density, an alteration in the height of the barometer, while the temperature remains the same, will produce no change in the velocity; for an increase of pressure, and consequently of elasticity, is accompanied by a proportional increase of density. An increase of temperature, however, by increasing the elasticity without changing the density, is accompanied by an augmentation of velocity. The correction for a difference of temperature is found as follows: Let t denote the number of degrees of temperature on Fahrenheit's scale above 32°, and a a constant coefficient; then the elasticity at the freezing temperature being e, the elasticity at the temperature t will be $e\,(1 + a\,t)$. But the value of a is found by experiment $= {\cdot}00208$; therefore the elasticity is $e\,(1 + {\cdot}00208\,t)$; and the formula for the velocity becomes $v = \sqrt{g\, m\, b\,(1 + {\cdot}00208\,t)}$; or, introducing the above value of $g\, m\, b$, $v = 916\,(1 + {\cdot}00104\,t)$.

The velocity of 916 feet at the freezing temperature, thus deduced from theory, falls short of the experimental velocity (which has been shown above to be 1089 feet) by 173 feet, or about a sixth part of the whole quantity. This discrepancy was remarked by Newton, who attempted to account for it by supposing the spherical molecules of air to be perfectly elastic solids, through which sound is propagated instantaneously; but the true solution of the difficulty was reserved for Laplace. The explanation given by Laplace is, that the compression of the air which takes place in the vibration disengages a portion of latent heat, which thus becomes sensible, and modifies the law of the elasticity, and accelerates the velocity. On submitting this to calculation, he found that the formula for the velocity of sound must be multiplied by a certain factor, namely, the square root of the quotient which is found by dividing the number which expresses the specific heat of the air (or other gas) under a constant pressure by that which expresses its specific heat under a constant volume. Let $k =$ this factor; then Laplace's formula for the velocity of sound is

$$v = \sqrt{g\, m\, b\,(1 + {\cdot}00208\,t)\,k}.$$

The value of k for atmospheric air, as determined by Dulong (*Lamé*, vol. ii. p. 87.), is 1·421; hence $\sqrt{k} =$ 1·192, and the formula in numbers is

$$v = 916 \times 1{\cdot}192\,(1 + {\cdot}00104\,t) = 1092 + 1{\cdot}14\,t,$$

which is almost identical with the experimental determination.

Velocity of Sounds through Liquids and Solids.— The

following general formula for the velocity with which sound is propagated through any elastic compressible body, whether liquid or solid, was found by Laplace: — Let b denote (as before) the standard height of the barometer, D the density of mercury at the freezing temperature, d the density of the medium, and c the *compressibility* of the medium, that is, the diminution of bulk it sustains by an additional pressure equal to one atmosphere; then the formula is $v = \sqrt{\frac{g\,b\,D}{c\,d}}$; or, (since $g = 386{\cdot}29$ inches, $b = 29{\cdot}927$ inches, $D = 13{\cdot}568$), $v = 396{\cdot}04\ \sqrt{(1 \div c\,d)}$ inches, or $33\ \sqrt{(1 \div c\,d)}$ feet per second. Applying this to the case of water, we have $c = {\cdot}000049589$ (Herschel, *Ency. Metrop.*), and $d = 1$; whence $v = 4687$ feet per second. This result agrees very nearly with the velocity determined by Culladon and Sturm by direct experiment on the propagation of sound through the lake of Geneva, the velocity actually observed by them being 1435 mètres, or 4708 English feet, which differs from the theoretical velocity only by 21 feet,—a space described by the aqueous pulse in the 200th part of a second.

By the above formula the velocity of sound through any medium of which the compressibility is known is readily computed. According to Chladni the velocities of sounds in different solids, that of air being taken as unity, are as follows: — Tin = 7½, silver = 9, copper = 12, iron = 17, glass = 17, baked clay = 10-12, woods of different kinds = 11-17. But the velocity of propagation through cast-iron tubes was determined experimentally by Biot, and found to be only about 10½ times its velocity in air. (See *Herschel's Treatise on Sound;* Chladni, *Traité d'Acoustique;* Biot, *Traité de Physique;* Pouillet, *Elémens de Physique;* Lamé, *Cours de Physique*, &c.)

SOUND. In Geography, a strait or inlet of the sea; applied specially to the strait which connects the German Sea with the Baltic.

SOUND BOARD. A thin board placed over the head of a public speaker to strengthen or extend the sound of his voice.

SOUTH. One of the four cardinal points of the compass; the direction in which the sun always appears at noon to the inhabitants of the northern hemisphere without the tropic.

SOUTHCO'TTIANS. In Religious History, the followers of Joanna Southcott, whose singular life and influence, although now nearly forgotten, deserve to be kept in record as examples of the contagious effects of fanaticism. She was born at Gittisham, in Devonshire, in 1750; and seems to have first persuaded herself of her miraculous calling in 1792. From that time she was in the habit of publishing pamphlets in an enthusiastic strain; traversed the west of England, preaching and prophesying, with a select body of followers, and gradually collected about her a considerable number of disciples. She came to town about 1803, when she announced a meeting, which she called her trial, for the purpose of satisfying the world of the reality of her mission. Several such meetings took place, the last in 1804; and many persons, including several clergymen, attested their belief in her pretensions. After this she became the founder of a church, which had a chapel in Duke's Place, where service was performed by a Mr. Tozer, a Dissenting clergyman of Exeter, who followed her to London. At last she announced her supernatural pregnancy; and this strange announcement took great hold on the public imagination, in consequence of Dr. Reeve and other medical men having declared their belief that she was actually pregnant in her 65th year. The excitement produced in London, in the summer of 1814, by the whole affair, was to be paralleled only by that which other delusions as absurd and impious have at different times occasioned. Her death, in December of that year, did not undeceive her disciples: even when her body was opened, four days after it, and no trace discovered to verify her assertions, many of them continued to proclaim their belief in her future reappearance. Her sect continued to exist for many years, nor are we aware that it is yet extinct. Many of its followers wore long beards, and a peculiar costume.

SO'VEREIGN. In Politics, a person, or body of persons, in whom the legislative authority rests in every state. A sovereign state is one in which the jurisdiction of that person or body, within the limits of the state, is absolute and uncontrolled by any foreign authority. The states which composed the German empire were termed, in the language of politics, "mi-souveraines;" because their sovereignty was qualified by their subordination, in some respects, to the imperial authority. The same term should seem applicable to the several states in the American Union, which are commonly, but improperly, termed sovereign; as, on some definite subjects, the power of their legislative bodies is subordinate to that of congress, or the sovereign body in the federal government.

SOVEREIGN. An English coin of the value of twenty shillings, the standard weight of which is 5 pennyweights and 3·27 grains, or 123·374 troy grains.

SO'WING. Depositing seed in the soil for the purpose of producing plants. The operation of sowing is generally performed in spring, in order that the plants may have the advantage of the coming summer. The seed is either scattered abroad, or deposited in rows or drills: on a small scale by the hand, and on a large scale by a sowing machine. Some seeds which are of large size are planted singly. The covering of seeds is greater or less, according to their size and the texture of the soil. Where the soil is somewhat firm, and the seed is pressed into it by a roller or by other means, and where the climate is moist, very little covering is necessary; but where the soil is loose, and the climate dry and warm, the covering should be twice or thrice the thickness of seeds. As the seeds of plants are the natural food of birds, insects, and vermin, in a state of culture artificial protection is required from their natural enemies.

SOWING MACHINE. A machine for depositing seeds in the soil, either equally over its surface or in rows. The simplest machine, and perhaps the most efficient for sowing seeds broadcast, is a hollow cylinder, pierced with holes, about the average size of the seed to be sown. This will deposit them at a greater or lesser distance asunder, according to the velocity with which it is turned round. Machines for sowing seeds in rows are termed drills. See DRILLS.

SPA. A place celebrated for its mineral waters, situate about seven leagues from Aix-la-Chapelle. The term is now generally applied to places at which there are mineral springs.

SPACE (Lat. spatium), signifies generally extension in all directions. Sometimes it has a less general signification; thus Euclid says, two straight lines cannot inclose a space, that is, an area.

SPACE. In Music, the void between the lines in a musical staff. The spaces are four in number, and the lines five.

SPA'DIX. A form of inflorescence in which the flowers are arranged around a fleshy rachis, and enclosed within a kind of bract called a spathe, as in palms and araceous plants.

SPAHI'S, or SIPAHIS. A part of the Turkish cavalry were so called. The word has the same derivation with *Sepoy*.

SPAN, in ordinary language, signifies a measure taken from the space between the thumb and the middle finger, both being extended. In Architecture and Engineering, it is applied to the extent or spread of an arch between its piers or abutments.

SPA'NDREL. (It. spandere, *to spread.*) In Architecture, the space about the flanks or haunches of an arch or vault above the intrados, and not higher than its crown.

SPA'NKER, or DRIVER. The name of the gaff sail set on the mizzen mast of a ship.

SPA'NNER. An iron instrument used in the manner of a lever to tighten the nuts upon screws. There is usually a notch at either end of the spanner, to suit nuts and screw-heads of different sizes.

SPAR. (Germ. spath.) A mineralogical term, applied to certain crystallized substances which easily break into cubic or prismatic, or other fragments, with polished surfaces; hence also the term *spathose*, applied generally to minerals of a sparry fracture.

SPAR, FLUOR, or DERBYSHIRE. Fluoride of calcium. *See* FLUOR SPAR.

SPAR, HEAVY. Sulphate of baryta. *See* BARYTA.

SPAR, ICELAND. Rhomboidal carbonate of lime.

SPA'ROIDS, *Sparoides*. The name of a tribe of Acanthopterygian fishes, of which the genus *Sparus* is the type. The palate is edentulous, but the jaws are generally well armed with teeth: sometimes these are all of a conical form, adapted for killing and lacerating; sometimes they are all rounded and obtuse, fitted for bruising. In some species, the anterior teeth are shaped according to the laniary type, and the posterior ones are grinders; in others, the anterior teeth resemble the human incisors. The genera of Sparoid fishes are chiefly founded on these dental modifications.

SPA'RROW-HAWK. The name of the *Falco nisus* of Linnæus, *Accipiter fringillarius* of Ray; which latter name is retained in modern ornithology for the subgeneric denomination of this small Raptorial bird.

SPARS. In Architecture, a term used in the provinces to denote the common rafters of a roof, as distinguished from the principal rafters.

SPASM. (Gr. σπασμος, *a cramp.*) An involuntary contraction of the muscles, generally attended by pain.

SPATA'NGUS. (Gr. σπαταγγος, *a species of Echinus.*) The name of a genus of *Echinidæ*, or sea-urchins, having the mouth situated laterally, and but four rows of pores.

SPATHE. In Botany, a large and coloured bractea situated at the base of a spadix, enclosing the latter, and supposed to perform the office of corolla.

SPA'TULATE. (Lat. spathulum, *a broad knife to spread salve with.*) In Zoology, when a substance or part of an animal is flattened, and broader and rounder at the apex, narrow at the base.

SPEA'KER. The presiding officer in each house of parliament is so termed. The lord chancellor, keeper of the great seal, or other person holding the king's commission, is ex-officio speaker of the House of Lords; and if there be none such, it is said the house may elect. He can speak and vote on any question. The speaker of the House of Commons is chosen by the house. Formerly, it was customary (see *Hatsell's Precedents of Parliaments*, vol. ii.) that persons holding high offices under the crown should be elected to this dignity. The speaker chosen must be approved of by the crown. The speaker cannot speak or vote except in a committee, when he is out of the chair; or in case of an equality of voices, when he exercises the privilege of giving a casting vote. The office of the speaker of the House of Commons, in addition to keeping order and controlling the debates of the house, is to issue warrants to the clerk of the crown to make out new writs for the election of members when seats are vacant. This power he exercised only by virtue of orders of the House of Commons, until the passing of the stat. 10 G. 3. c. 41., by which he was enabled to issue the writs during a recess. *See* PARLIAMENT.

SPEA'KING TRUMPET. *See* TRUMPET.

SPE'CIALTY. In Law, any instrument in writing under seal. Specialty creditors are those who have their debts secured to them by deed, in opposition to creditors on simple contract. The advantages of the former security are, that it has priority in the distribution of assets; and that specialty debts in general are not presumed satisfied until after the lapse of twenty years, whereas simple contract debts are buried in six by the Statute of Limitations.

SPECIE. A term used for gold and silver coin, in contradistinction to *paper money*.

SPE'CIES. (Lat.) In Logic, a predicable which is considered as expressing the whole essence of the individuals of which it is affirmed. The essence of an individual is said to consist of two parts: 1. The material part, or genus; 2. The formal or distinctive part, or difference. The genus and difference together make up, in logical language, the species: *e. g.* a "biped" is compounded of the genus "animal," and the difference "having two legs." It is obvious that the names *species* and *genus* are merely relative; and that the same common terms may, in one case, be the species which is predicated of an individual, and in another case the individual of which a species is predicated: *e. g.* the individual, Cæsar, belongs to the species man; but man, again, may be said to belong to the species animal, &c., as we contemplate higher and more comprehensive terms. A species, in short, when predicated of individuals, stands in the same relation to them as the genus to the species; and when predicated of other lower species, it is then, in respect of these, a genus, while it is a species in respect of a higher genus. Such a term is called a subaltern species or genus; while the highest term of all, of which nothing can be predicated, is the "summum genus;" the lowest of all, which can be predicated of nothing, the "infima species." The difference which, together with the genus, makes up the species, is termed the "specific difference." *See* PREDICABLE, LOGIC.

SPECI'FIC. In Medicine, this term is applied to remedies the effects of which upon particular diseases are little liable to fallacy and uncertainty; hence cinchona is called a specific in certain forms of intermittent fever, and mercury in syphylis, &c. A *specific character* is that which peculiarly and certainly distinguishes one thing from another.

SPECIFIC GRAVITY. *See* GRAVITY.

SPE'CTACLES. An optical instrument, consisting of two lenses set in a frame, for assisting or correcting the defects of imperfect vision. The lenses are convex or concave, according to the nature of the defect to be remedied. In old age the pupil of the eye becomes flat, and the rays of light are consequently not refracted sufficiently in passing through it to meet on the retina and produce distinct vision. This defect is remedied by a convex lens, which produces a slight convergency of the rays before they enter the eye. Short-sighted people, on the contrary, require concave lenses; because, in their case, the indistinctness of vision proceeds from too great a curvature of the pupil, which causes the rays to meet in a point before they reach the retina, — a defect which is remedied by giving the rays a slight divergency before they enter the eye.

Spectacles appear to have been first used about the latter end of the 13th century; but the date and author of the invention are not certainly known, and have been much disputed. It seems most probable that the first hint of their construction and use was taken either from the writings of Alhazen, who lived in the 12th century, or of Roger Bacon, who died about 1292. A passage in the *Opus Majus* of the latter renders it certain, at least, that he was acquainted with the use of crystalline lenses in magnifying minute or distant objects. (See *Smith's Optics*, "Remarks," art. 8. 5—90.)

SPE'CTRES, *Spectra*. A name given by Stoll and Latreille to a family of Orthopterous insects, comprehending those which have a linear and attenuated body, like the ghost of an insect.

SPE'CTRUM. (Lat. spectrum, *image*.) In Optics, the name given to an elongated image of the sun or other luminous body, formed on a wall or screen by a beam of undecomposed light received through a small hole, and refracted by a prism. For the different colours and fixed lines of the solar spectrum, see CHROMATICS; and for the refrangibility of the different rays, REFRACTION.

SPE'CULUM. (Lat. speculum, *a mirror*.) In Optics, the term *speculum* is usually appropriated to reflectors formed of polished metal; while the term *mirror* is used to signify a reflector of glass. For the focal distances and laws of reflexion of spherical specula, see REFLEXION; and for a description of the method of casting and polishing large specula for reflecting telescopes, see Sir W. Herschel's Description of his Telescope in the *Phil. Trans.* for 1795; Brewster's edition of *Ferguson's Lectures;* and Lord Oxmantown's Account of Experiments on the Reflecting Telescope, in the *Phil. Trans.* for 1840.

SPE'CULUM METAL, with which mirrors for reflecting telescopes are made, is an alloy of two parts of copper and one of tin; its whiteness is improved by the addition of a little arsenic.

SPELL. (Ang. Sax. spel, *story* or *tale*.) Any form of words, written or spoken, supposed to be endowed with magical virtues. This superstition seems common to every race of man; but it was more peculiarly prevalent among the ancients. The lines of Horace —

> Sunt verba et voces, quibus hunc lenire dolorem
> Possis, &c. —

probably refer to the belief in the efficacy of magical words in alleviating pain and disease. There is an amusing article upon this subject in the *Encyclopædia Metropolitana*.

SPE'LTER. The commercial term for zinc.

SPERMACE'TI. This substance concretes or crystallizes spontaneously out of the oil of the spermaceti whale. It is purified first by pressure, then by fusion and boiling with a weak alkaline ley. When melted in masses, it concretes in crystalline plates of a silvery lustre and unctuous feel. It fuses at about 100°. It dissolves in boiling alcohol; and as the solution cools it separates in brilliant scales, to which Chevreul has given the name of *cetine*.

SPERMI'DIUM. (Gr. σπερμα, *a seed*.) A kind of small seed-vessel, resembling a seed, and more commonly called an *akenium*.

SPHA'CELUS. *See* GANGRENE.

SPHÆRISTE'RIUM. (Gr. σφαιρα, *a sphere or ball*.) In ancient Architecture, a circular court for playing tennis, or other exercises. *See* BALL.

SPHENE. Native silico-calcareous oxide of titanium.

SPHENO'ID BONE. (Gr. σφην, *a wedge*.) One of the bones of the head; so called from its being wedged in, as it were, amongst the other bones. It is of a most irregular shape, and very complicated in its processes and connections with the other bones. When removed, it is something of the figure of a bat with its wings extended. It is connected with all the bones of the skull, and with those of the palate, cheeks, and upper jaw.

SPHERE. (Gr. σφαιρα.) In Geometry, a solid body described by the revolution of a semicircle about its diameter; or it may be defined to be a body bounded by a surface of which every point is equally distant from a single point within the surface, called the centre of the sphere. If r denote the radius of the sphere, and x, y, z the rectangular co-ordinates, the origin being at the centre, the equation of the surface is $x^2 + y^2 + z^2 = r^2$.

The following are some of the principal properties of the sphere: — 1. The surface of the sphere is equal to four times the area of one of its *great circles;* i. e. of a section made by a plane passing through its centre. 2. The curve surface of any zone, or portion contained between two parallel planes, is equal to the curve surface of a cylinder of the same height with the height of the zone, or the distance between the planes, and of the same diameter with the sphere. Hence it follows that the whole surface of the sphere is equal to the curve surface of the circumscribing cylinder. 3. The solid content of a sphere is equal to that of a pyramid whose altitude is the radius, and whose base is equal to the surface of the sphere; and hence the content of the sphere is one third of the product of its radius into its surface. 4. The sphere is equal to two thirds of its circumscribing cylinder.

Let r denote the radius of the sphere, s its superficies, c its solid content, and π the ratio of the semicircumference to the radius $= 3{\cdot}14159$; then, since the area of a circle of which r is the radius is πr^2, the properties above stated give the relations which follow; viz.

$$\text{Surface} = s = 4\pi r^2 = 12{\cdot}56637 \times r^2,$$

$$\text{Content} = c = \tfrac{1}{3} r s = \tfrac{4}{3}\pi r^3 = 4{\cdot}18859 \times r^3.$$

If we suppose the diameter $= 1$, and consequently $r = \frac{1}{2}$, these relations become $s = \pi$, $c = \frac{1}{6}\pi$.

SPHERE. In Astronomy, the concave expanse of the heavens, which, having no definite limit, appears to the eye as the interior surface of a sphere enclosing the earth, which is placed at the centre. The ancients gave the name of sphere to the orbits of the several heavenly bodies; thus, the sphere of Jupiter, the sphere of Saturn, the sphere of the fixed stars. In the Ptolemaic astronomy, the different spheres were supposed to be solid and transparent, moving about their common centre independently of each other, and each carrying its appropriate body along with it.

SPHERE, in Geography, denotes a representation of the earth on the surface of a globe, which has also represented on it an assemblage of circles showing the positions of the equator, ecliptic, meridians, &c. The ancients gave different appellations to the sphere, according to the inclination of the earth's axis to the horizon. When the poles are in the horizon, it was called a *right sphere;* when the poles are in the zenith and nadir, a *parallel sphere;* and in every other position, an *oblique sphere.*

SPHE'RICAL. Relating to a sphere. Thus, a *spherical angle* is an angle formed on the surface of a sphere by the intersection of two great circles, or circles whose planes pass through the centre; and a *spherical triangle* is a triangle formed by the intersecting arcs of three such circles. For the properties of spherical triangles, see TRIGONOMETRY.

SPHE'RICAL EXCESS, in Trigonometry, is the sum by which the three angles of any triangle on the surface of a sphere or spheroid exceeds two right angles. Let the three angles of a spherical triangle be denoted respectively by A, B, C, and let E represent the spherical excess; then, by the above definition, $E = A + B + C - 180^{\circ}$. Now, in any spherical triangle the sum of the three angles is always greater than two and less than six right angles; consequently E may have any value not exceeding four right angles.

In Geodesy, the angles of each triangle are determined by instrumental measurement, and are consequently subject to the errors of observation. But in order to compute the sides of the triangle with the requisite accuracy, it is necessary that the amount of the error in the sum of the three angles be known; and it is therefore necessary to determine the spherical excess independently of extreme precision in the values of the angles. Let S denote the area of the triangle, r the radius of the sphere, and π the ratio of the circumference to the diameter ($= 3{\cdot}14159$); then, by trigonometry,

$$S = \frac{A + B + C - 180^{\circ}}{180^{\circ}} \times r^2 \pi;$$

whence, since $E = A + B + C - 180^{\circ}$, we have $E = \frac{S \times 180^{\circ}}{r^2 \pi}$ in degrees, or $E = \frac{S \times 648000''}{r^2 \pi}$, expressed in seconds. In any triangle that can be measured on the surface of the earth S is very small in comparison of r^2, and E is therefore a very small quantity, seldom amounting to more than five or six seconds (though, in some of the large triangles of the British survey, where the sides were nearly 100 miles in length, it amounted to upwards of 30''); and therefore an approximate knowledge of the value of S, and of the radius r, within the limits of any probable error, will suffice to give E correct to the 100th part of a second. Hence, for computing the value of E, the triangle may be considered a plane one, and the value of S computed from approximate values of two of its sides and the included angle. If, therefore, a and b denote the number of feet in the sides opposite the angles A and B respectively, we shall have $S = \frac{1}{2} a\, b \sin. C$; and if we also assume $m = 648000 \div 2\, r^2 \pi$ (where r is expressed in feet), the logarithm of E in seconds will be found from this formula,

$$\log. E = \log. a + \log. b + \log. \sin. C + \log. m.$$

For the middle of England, the radius of an arc intersecting the meridian at an angle of 45° is 20,941,000 feet, nearly. Assuming this to be the value of r, then $\log. m = 9{\cdot}62860$.

SPHE'RICS. In Geometry, the doctrine of the properties of the sphere considered as a geometrical body, and, in particular, of the different circles described on its surface. *See* TRIGONOMETRY.

SPHE'ROID. (Gr. σφαιρα, and ειδως, *form.*) In Geometry, a solid generated by the revolution of an ellipse about one of its axes. If the generating ellipse revolves about its major axis, the spheroid is *prolate*, or oblong; if about its minor axis, the spheroid is *oblate*.

Let $2\,a$ be the axis of revolution, and $2\,b$ the diameter of the generating ellipse perpendicular to the axis; then the origin of the co-ordinates being at the centre, and x being taken on the semi-axis a, the equation of the surface of the spheroid is

$$\frac{x^2}{a^2} + \frac{y^2 + z^2}{b^2} = 1.$$

Let k^2 denote the ratio of the difference of the squares of a and b to the square of a; that is, make $a^2 k^2 = a^2 - b^2$, and put $\pi = 3{\cdot}14159$: then the whole surface S of the spheroid is expressed by the following series, in which the upper signs are to be used if the spheroid is oblong (that is, if a is greater than b), and the under signs if the spheroid is oblate: viz.

$$S = \pi\, a\, b \left(1 \mp \frac{1}{2\cdot3} k - \frac{1}{2\cdot4\cdot5} k^2 \mp \frac{3}{2\cdot4\cdot6\cdot7} k^3 - \&c.\right)$$

The solid content of any spheroid, whether oblate or oblong, is equal to two thirds of its circumscribing cylinder, and is therefore equal to $\frac{4}{3}\pi\, a\, b^2$. And since the content of a sphere, of which the radius is equal to a, is $\frac{4}{3}\pi\, a^3$, it follows that the content of the spheroid is to the content of a sphere whose diameter is equal to the axis of revolution as $b^2 : a^2$.

The oblate spheroid being the figure assumed by the earth and the other planets, its properties are of great importance in astronomy and geodesy. Newton demonstrated that the attraction of a sphere on any exterior body is the same as if all the matter in the sphere were collected into a point at the centre; but this property does not hold true of spheroids, and the calculation of the effects of attraction is thereby rendered greatly more difficult. *See* GRAVITATION.

In geodetical operations, it is necessary to have regard to the curvature of the spheroidal surface of the earth. Supposing the elements of the spheroid (that is, the polar and equatorial axes) to be known, the curvature of the surface at any place of which the latitude is given is determined by the following formulæ:—

Let a be half the polar axis, b the radius of the equator, e the ellipticity, or a number such that $b = a\,(1 + e)$ (*see* ELLIPTICITY), and l the given latitude. Also, let r be the radius of curvature in the direction of the meridian, r' the radius of curvature in the direction perpendicular to the meridian, and R the radius of curvature of a normal section, making with the meridian an angle $= \theta$; then

$$r = a\,(1 - e + 3\,e \sin.^2 l) \;.\;.\;.\; (1.)$$

$$r' = a\,(1 + e + e \sin.^2 l) \;.\;.\;.\;.\; (2.)$$

$$R = \frac{r\, r'}{r \sin.^2 \theta + r' \cos.^2 \theta} \;.\;.\;.\;.\;.\; (3.)$$

Dividing the numerator and denominator of this last expression by r', substituting $1 - \sin.^2 \theta$ for $\cos.^2 \theta$, and converting the result into a series, of which it is sufficient to retain only the two first terms, we obtain the following, which is more convenient for calculation,

$$R = r\left(1 + \frac{r' - r}{r'} \sin.^2 \theta\right)$$

SPHERO'METER. (Gr. σφαιρα, and μετρον, *measure.*) In Physics, an instrument for measuring with great precision the thickness of small bodies, the curvature of optical glasses, &c.

SPHE'RULITE. A term applied by some mineralogists to a variety of obsidian or pearlstone, which occurs in rounded grains.

SPHIGMO'METER. (Gr. σφιγμος, *the pulse.*) An instrument for counting the arterial pulsations.

SPHI'NCTER. (Gr. σφιγχω, *I close.*) A term applied by anatomists to several muscles which close or contract the orifices which they surround.

SPHINX. A fabled monster, half woman and half lion, said by the Grecian poets to have infested the city of Thebes, devouring its inhabitants till such time as a riddle it had proposed to them should be solved. This was done by Œdipus, who slew the sphinx, and was, by the gratitude of the Thebans, chosen their king. The Grecian sphinx was probably borrowed from Egypt; where the enormous figure, now half buried in the sand, was probably the archetype of the more elegant monster of Greece. This figure is close to the Pyramids of Ghizeh, and was disinterred by the late Mr. Belzoni, but has been again nearly covered. It has been said (on the authority of Pliny) that the sphinx represented the Nile in a state of flood; that event regularly occurring under the signs of the Virgin and Lion. But others contend that the original Egyptian sphinx was male (Androsphinx), like the specimen described by Herodotus, book ii. (*Wilkinson's Ancient Egyptians.*) But the greater part of the enormous number around the temples of Luxor (1500 in a single avenue) are said to be female. (*Libr. of Entertaining Knowledge.*) Sphinxes are also represented with the heads of rams and hawks (Criosphinx, Hieraco-sphinx). The Egyptian sphinx had no wings; these appendages were added by the Greek artists.

SPHRAGI'STICS. (Gr. σφραγις, *a seal.*) The science of seals, their history, peculiarities, and distinctions, especially with a view to the means which they afford of ascertaining the age and genuineness of documents to which they are affixed. Ancient seals were chiefly impressed on common wax of different colours; sealing-wax came into use in the sixteenth century. This branch of diplomatics owes its origin to Heineccius, who

published a work on the subject in 1709. Gercken's treatise, styled *Anmerkungen über die Siegel zum Nutzen der Diplomatik* (Augsburg, 1781), will be found a useful guide.

SPICCA'TO. (It. *divided.*) In Music, a term indicating that every note is to have its distinct sound. When used in relation to instruments played with a bow, it is to be understood that every note is to have a bow distinct from the preceding or succeeding one.

SPI'DER. *See* ARACHNIDÆ.

SPIKE. In Botany, a form of inflorescence in which all the flowers are sessile along a common axis, as in *Plantago*.

SPI'NDLE. In Geometry, a solid generated by the revolution of a curve line about its base or double ordinate. The solid generated by the revolution of a curve about its axis is called a *conoid*. In Mechanics, *spindle* denotes the axis of a wheel or roller.

SPINE. *See* VERTEBRÆ.

SPINE'L. (Fr. spinelle.) A subspecies of the ruby. It is of various colours, such as red, brown, yellow, and sometimes blue; its colouring matter is sometimes oxide of chromium, but generally oxide of iron. It usually contains from 80 to 84 per cent. of alumina, and from 8 to 10 of magnesia.

SPINELLA'NE. A term applied by some mineralogists to a dodecaëdral variety of zeolite of a blueish or brownish colour, found near Andernach on the Rhine. Its essential components are silica, alumina, and soda.

SPINES. Branches that, being imperfectly formed, lose their power of extension, become unusually hard, and acquire a sharp point. They are very different from aculei, or prickles, which are a kind of hardened hair. In leaves, they are processes formed either by an elongation of the woody tissue of the veins, or by a contraction of the parenchyma: in the former case, they project beyond the surface or margin of the leaf, as in the holly; in the latter case, they are the veins themselves become indurated, as in the palmated spines of *Berberis vulgaris*.

SPINE'T. A musical stringed instrument with a key-board, &c., similar in construction to a harpsichord; from which, indeed, it little differs, except in being much smaller. Its general form is that of the harp, and it was originally called the *couched harp*.

SPI'NNERS, or SPINNERETS. In Entomology, organs with which insects form their silk or webs. In spiders they consist of two retractile pieces issuing from anal protuberances, and giving out the threads.

SPINNING. *See* COTTON MANUFACTURE.

SPINNING JENNY. *See* COTTON MANUFACTURE.

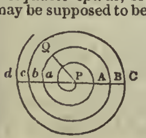
SPINO'SISM. In Philosophy, the system of Benedict Spinosa, a Jew of Amsterdam, born in 1634, which is developed in his work on ethics. In it he deduces by strictly mathematical reasoning, from a few axioms, the well-known principles, that "there can be no substance but God; whatever is is in God, and nothing can be conceived without God." Hence his scheme is called with justice Pantheistic. In fact, as Mr. Hallam observes, "he does not essentially differ from the Pantheists of old. He conceived, as they had done, that the infinity of God required the exclusion of all other substance; that he was infinite *ab omni parte*, and not only in certain senses." "It was one great error of Spinosa," says the same writer, "to entertain too arrogant a notion of the human faculties; in which, by dint of his own subtle demonstrations, he pretended to show a capacity of adequately comprehending the nature of what he denominated God. And this was accompanied by a rigid dogmatism, no one proposition being stated with hesitation; by a disregard of experience, at least as the basis of reasoning; and by a uniform preference of the synthetic mode." (*Literature of Europe*, vol. iv. p. 243. &c.; and see *Brucker's History of Philosophy*, vol. iii.; *Stewart's Introductory Essay to the Encyclopædia Britannica*.)

SPI'NTHERE. A mineral of a greenish grey colour, found in the department of the Isere in France.

SPI'RACLES, or SPIRACULA. (Lat. spiro, *I breathe*.) In Entomology, the breathing pores of insects are so called.

SPIRAL. In Geometry, the name given to a class of curves distinguished by this general property, that they continually recede from a centre or pole, while they continue to revolve about it. Spirals receive different names from the properties by which they are characterized, or from their inventors; thus, the *equable spiral*, the *hyperbolic spiral*, the *logarithmic spiral*, the *spirals of Cotes*, &c.

Equable spiral, or *spiral of Archimedes*. This curve may be supposed to be generated as follows:—If a straight line P A B C turn uniformly about its extremity P, a point in the straight line which advances from P with a uniform motion and arrives successively at *a*, A, *b*, B, *c*, C, *d*, will describe the spiral. The point P is called the pole, and the portion of the revolving line intercepted between the pole and any point of the curve is the *radiant*, or radius vector at that point. Let Q be a point in the spiral, make the radiant P Q $= u$, and let θ be the angle described by the revolving line while the travelling point advances from P to Q; then, since from the definition the radiant u and the angle θ are both proportional to the time, they are proportional to each other; and the polar equation of the equable spiral is $u = a\,\theta$, where a is a constant. If we suppose $u = r$ when the revolving line has made a complete revolution, or when $\theta = 2\pi$; then $a = r \div 2\pi$, and the equation becomes $u = \frac{r}{2\pi}\,\theta$.



Some of the principal properties of this spiral are the following:—1. The area of the spiral P a A b Q is equal to $\frac{u^3}{6a} = \frac{\pi u^3}{3r}$. If $u = r$, this becomes $\frac{1}{3}\pi r^2$; or the area generated while the revolving line makes one revolution, is equal to a third of a circle whose radius is r. If $u = 2r$, the expression for the area becomes $\frac{2}{3}\pi (2r)^2$; and the spiral area is therefore the third part of a space that is double of a circle described with a radius $= 2r$. And generally the whole area generated by the radiant, from the beginning of the motion till after any number of revolutions, is equal to the third part of a space which is the same multiple of the circle whose radius is equal to the greatest radiant as the number of revolutions is of unit. 2. The arc of the spiral between its origin and the radiant u is equal to that of a parabola whose *latus rectum* is $2a$ included between the vertex and an ordinate $= u$, and the corresponding area of the spiral is equal to one half the corresponding area of the parabola. 3. The subtangent to any point Q of the spiral is equal to the arc of a circle described by the radiant P Q; and hence at the termination of the first, second, third, fourth, &c. revolutions, the corresponding subtangents are as the series of square numbers, 1, 4, 9, 16, &c.; for the second, third, fourth, &c. the subtangents are equal to 2, 3, 4, &c. circumferences, whose radii are at the same time doubled, tripled, quadrupled, &c.

The equable spiral was proposed by Conon to Archimedes, who, in his treatise Περι Ελιχων, has investigated its quadrature, and some of its chief properties.

The *hyperbolic spiral* belongs to a class of spirals of which the general equation is $u = a\,\theta^{-n}$. If we suppose $n = 1$, we have $u = a\,\theta^{-1}$, or $u\,\theta = a$, which is the equation of the hyperbolic spiral; and from which it follows, that if from a point in a straight line, given by position, arcs be described of a given length, and having each one extremity in the given straight line, the locus of their other extremities will be in the spiral.

This curve was proposed by James Bernoulli, and has been called the hyperbolic spiral, from the analogy between its polar equation and the equation to rectangular co-ordinates of the common hyperbola, when referred to its asymptotes; namely, $x\,y = $ A, a constant area.

The *logarithmic spiral* differs from the equable spiral in this respect, that the point which describes the curve, instead of advancing equably along the uniformly revolving straight line, is carried along it with a velocity increasing in proportion to the distance from the centre. This curve, which was noticed by Des Cartes, has many remarkable properties, of which the more abstruse were investigated by James Bernoulli. *See* LOGARITHMIC SPIRAL.

For the investigation of the properties of spirals, see *Leslie's Geometrical Analysis; Peacock's Examples of the Differential and Integral Calculus; Maclaurin's Fluxions*, &c.

SPI'RAL VESSELS, in Plants, are membranous tubes with conical extremities, lined in the inside by a fibre twisted spirally, and capable of unrolling with elasticity; their function is that of the conveyance of air. They are found in almost any part of plants except the bark; but are most abundant in leaves and flowers, and least common in the stem and root, except in the medullary sheath of the former.

SPIRE. (Gr. σπειρα, *a twisting*.) In Architecture, among the ancients, the base of a column: also the astragal or torus of the base. In modern architecture, it is an erection above the tower of a church, which diminishes gradually as it rises; sometimes rising in the form of a plain slender pyramid, polygonal on the plane.

SPI'RIFER. The name of a genus of extinct Palliobranchiate mollusks, characterized by the shell having two internal calcareous spiral appendages.

SPI'RIT OF WINE. *See* ALCOHOL and FERMENTATION.

SPI'RITO, SPIRITO'SO (It. *spirit, with spirit*), in Music, denotes, when affixed to a movement, that it is to be performed in a spirited manner.

SPI'RITS. All inflammable liquors obtained by distillation, as brandy, rum, geneva, whisky, &c., are comprised under this designation. The manufacture of spirits is placed under the surveillance of the excise, and a very large revenue is obtained from it. The following statis-

tical accounts relative to spirits, &c., for the year ending Jan. 5. 1841, are extracted from a return laid before the House of Commons: — 1. It appears that during that period the total gallons of proof spirits distilled in the United Kingdom, and produced from malt and from a mixture of malt with unmalted grain, amounted to 22,021,394 gallons, of which 5,918,435 gallons were distilled in England, 8,821,530 gallons in Scotland, and 7,281,449 gallons in Ireland. 2. The total gallons of proof spirits on which duty was paid for consumption in the United Kingdom amounted to 21,859,337 gallons; the total amount of duty paid thereon having been 5,208,040*l*. Of these 21,859,337 gallons, there were 8,278,148 on which duty was paid for home consumption in England, 6,180,338 in Scotland, and 7,404,051 in Ireland. 3. The total number of gallons of proof spirits (made from various grain, &c.), imported into England from Scotland, was 2,056,640; into England from Ireland, 370,441; into Ireland from Scotland, 762,358; and into Scotland from Ireland, 6459; the gross total amount of duty paid upon all which was 1,028,294*l*. 4. The total number of gallons of proof spirits permitted out from distillers' stocks in England amounted to 5,864,950; and the total number of gallons proof of British brandy and spirits of wine, permitted out from rectifiers' stocks in England, was as follows, viz. British brandy 308,063 gallons, and spirits of wine 236,007 gallons. 5. The total number of proof gallons of foreign spirits (including rum, brandy, geneva, &c.) which paid duty in the United Kingdom, amounted altogether to 3,644,410; the net amount of duty paid upon which was 2,440,942*l*. Of this duty, England paid 2,352,550*l*., Scotland 66,134*l*., and Ireland 22,258*l*. If to the above quantities there be added the spirits of the manufacture of the United Kingdom, and of Jersey and Guernsey, the gross total number of gallons of spirits of all kinds that paid duty in the year 1840-41 will amount to 25,517,326, and the net amount of such duty to 7,654,233*l*. (For full particulars as to the operation of the duties upon spirits, see the *Com. Dict.*) *See* DISTILLATION.

SPI'RITUALISM, as distinguished from *Materialism*. That system according to which all that is real is spirit, soul, or self; that which is called the external world being either a succession of notions impressed on the mind by the Deity, or else the mere educt of the mind itself. The first is the spiritualism of Berkeley; the second, which may be called pure egoism, that of Fichte.

SPI'RULIDÆ. The name of a family of Dibranchiate Cephalopods, of which the genus *Spirula* is the type. They are chiefly characterized by having a spiral discoid chambered shell developed in the substance of the mantle, instead of a calcareous or horny plate.

SPLANCHNO'LOGY. (Gr. σπλαγνον, *an entrail*, and λογος, *a discourse*.) The doctrine of the viscera.

SPLAYED. (*Displayed, spread out.*) In Architecture, a term used to denote an angle which is cut off, or oblique.

SPLEEN. A spongy viscus, of an oval form, the use of which is unknown; placed in the human subject in the left hypochondrium, between the eleventh and twelfth false ribs. *Spleen* is also used for a species of hypochondriasis to which the English are said to be particularly open.

SPLENI'TIS. Inflammation of the spleen.

SPLE'NIUS. A flat muscle, situated between the back of the ear and the lower and posterior part of the neck.

SPLENT COAL. An inferior kind of cannel coal from the Scotch collieries.

SPLICE. In Naval language, to join the end of a rope with the end or bight of another, by untwisting the strands of both and laying them up again involved.

To *splice the main brace*, a term applied to an extra allowance of spirits in cases of cold or wet.

SPLINT. A piece of wood or pasteboard, so shaped as to support a broken or debilitated limb.

SPLINTERY. That fracture of minerals which is nearly even, but exhibits small splinters or scales thicker at one extremity than the other, and adhering by their thicker ends to the broken surface.

SPO'DUMENE. A mineral found in laminated masses, hard, brittle, translucent, and of various shades of green or grey. It was first discovered at Utoë, in Sweden. It consists of silica and alumina, with 8 to 10 per cent. of lithia. Before the blowpipe, it exfoliates into little scales of an ash colour: hence its name, from σποδυω, *to reduce to ashes*. It is also called *triphane*.

SPOLIA'TION, WRIT OF, in English Law, is obtained by one of the parties to a suit in the ecclesiastical courts suggesting that his adversary has wasted the fruits of a benefice, or received them to his prejudice. The suit founded on this writ lies for one incumbent against another, where they both claim by one patron, and the right of patronage is not in question.

SPO'NDEE. (Gr. σπονδη, *a libation.*) In Greek and Latin Poetry, the name of a foot consisting of two long syllables. It was so called because it was originally employed in the hymns sung in honour of the gods during the offering up of a sacrifice, for which it was admirably fitted from its grave structure. *Spondaic verse* is an hexameter line, in which the two last feet are spondees; instead of the usual termination, a dactylus and a spondee.

SPO'NDYLUS. (Lat. spondylus, *a spindle* or *shell fish*.) The name of a Linnæan genus of the Vermes Testacea, comprehending the spring oysters; characterized by having a strong tooth on each side of the depression lodging the elastic ligament of the hinge of the shell. The genus is included in the Ostracean family of the Acephalous Testacea by Cuvier, and has been subdivided by Lamarck into the genera *Spondylus* proper and *Plicatula*. Some of the species of *Spondylus*, as the water-clam (*Sp. varius*), form a series of chambers by secreting successive layers of nacreous shell at a distance from each other, the last chamber containing a quantity of fluid, which escapes by very slow evaporation through the pores of the calcareous shell.

SPONGE (Fr. eponge, Germ. schwamm), is a cellular fibrous tissue produced by small animals, almost imperceptible, called Polypi by naturalists, which live in the sea. This tissue is said to be covered in its recent state with a kind of semifluid thin coat of animal jelly, susceptible of a slight contraction or trembling on being touched; which is the only symptom of vitality displayed by the sponge. After death this jelly disappears, and leaves merely the sponge; formed by the combination of a multitude of small capillary tubes, capable of receiving water in their interior, and of becoming thereby distended. Sponges occur attached to stones at the bottom of the sea, and abound particularly upon the shores of the islands in the Grecian Archipelago. Although analogous in their origin to coral, sponges are quite different in their nature; the former being composed almost entirely of carbonate of lime; while the latter are formed of the same elements as animal matters, and afford on distillation a considerable quantity of ammonia.

Dilute sulphuric acid has been recommended for bleaching sponges, after the calcareous impurities have been removed by muriatic acid. Chlorine water answers better.

The sponges of commerce are usually prepared before they come to the market, by being beaten and soaked in dilute muriatic acid with a view to bleach them, and to dissolve any adherent portions of carbonate of lime. Three kinds are found commonly in the market, and known as the Turkey; the variety of the same, which is very rare; and the West Indian. On examining the living sponge of commerce with a power of about 500 linear, the fleshy matter will be distinctly observed, having in its interior gemmæ, which are considered to be the young. These are occasionally given off from the mass of living matter. The greater portion of the mass of sponge consists of small cylindrical threads or fibres, various in size. The spiculæ are not found within these, but in the large and flattened fibres, and varying in number from one to three or more, imbedded in their substance. Sometimes one spiculum projects a half or more from the side of the fibre, and is then only covered with the animal matter at the base, or half way up. The fibres of the West Indian species of sponge have been clearly proved to be solid. In the rare variety of Turkey sponge, the fibres are possessed of vessels which anastomose in various directions, differing much in size, and not imbedded in horny fibre, but in a separate sheath. This true vascular tissue performs very important functions in the economy of the animal during life. In some of the tubes of sponge have been observed small globules, the largest of which measured the 1666th of an inch, and the smallest the 50,000th of an inch. They were accidentally perceived to move from right to left. (See a Paper read by Mr. Bowerbank at a meeting of the Microscopical Society in 1841.)

SPONGE TENT, is formed by dipping sponge into hot melted wax plaister, and pressing it till cold between two iron plates: it is then cut into pieces, and used for dilating wounds.

SPO'NGIÆ. The name of a class of aquatic Zoophites composed of the different genera and species of sponge.

SPO'NGIOLE. In Botany, the lax cellular tissue and mucus situated at the extremities of roots, having the property of absorbing fluid like a sponge; whence the name.

SPO'NSIONS. In International Law, acts and engagements made on behalf of states by agents not specially authorized, or exceeding the limits of the authority under which they purport to be made, are so called by writers on this branch of jurisprudence. Such conventions must be confirmed by express or tacit ratification; the latter of which is implied from the fact of acting under it as if bound by its stipulations; but mere silence is not, in general, held equivalent to ratification. Such are the official acts of admirals and generals suspending or limiting hostilities, capitulations of surrender, cartels of exchange, &c. (See Grotius, *De Jure Bel. et Pac.* lib. iii.;

Vattel, liv. ii.; Wheaton, *On International Law*, vol. i. p. 291.)

SPO'NSORS. In the Roman Catholic, Greek, Lutheran, and Calvinistic Churches on the Continent, and in the Church of England, the name given to the parties who at the baptism of infants make a profession of the Christian faith in their name, and guarantee their religious education. (See *Neander's Church History*, vol. i. part 2.) In the Presbyterian Church, baptism is administered without sponsors.

SPOO'NDRIFT. The light spray blown off the waves in a violent wind.

SPO'RADIC. (Gr. σπειρω, *I sow.*) A term applied to such diseases as attack a few persons at a time.

SPORANGI'UM. (Gr. σπορα, *a seed*, and αγγειον, *a vessel.*) The case in which the reproductive matter of ferns, mosses, and many other Cryptogamic plants is enclosed. Sporangiolum is the same part, when so small as to be microscopic.

SPORI'DIA. (Gr. σπορα, and ειδος, *form.*) A term used in describing Algæ and Characeæ, to denote the granules which resemble sporules, but which are of a doubtful nature. Also in describing Fungi, to indicate the immediate covering of the sporules.

SPORIDIO'LA. The sporules or reproductive granules of Fungi.

SPO'RTUM, SPORTULA. In Roman Antiquities. It was an ancient usage in Rome for rich men to distribute victuals on certain occasions among their poor clients, each of whom attended for the purpose with a wicker basket (sportum). Afterwards this dole was generally commuted for money; and the sum thus distributed, about 100 quadrantes, or eighteen pence English, was called *sportula*.

SPO'RULES, or SPORES. (Gr. σπορα, *a seed.*) The reproductive bodies of Asexual or Cryptogamic plants; differing from seeds in not being generated by impregnation, and in having no definite and predetermined points of growth, but springing forth into young plants from any part of their surface.

SPOTS ON THE SUN. *See* SUN.

SPRING. In Astronomy, one of the four seasons of the year. For the northern hemisphere, the spring season begins when the sun enters Aries, the first of the northern signs, or about the 21st of March, and ends at the time of the summer solstice. *See* SEASONS.

SPRING. In Mechanics, a piece of mechanism, formed of tempered steel or some other elastic substance, applied mostly for the purposes of producing resistance, or of preventing a shock from the collision of hard bodies, or of giving motion to mechanism by its effort to unbend itself. For the law of the force exerted by a spring, see ELASTIC CURVE.

SPRING. In Natural History. *See* FOUNTAIN.

SPRING. In Naval language, a rope or hawser by which a ship is held at one part, as the bow or quarter, in order to keep her in a particular position, or to turn her in a short compass.

SPRINGING. In Architecture, the lower part of an arch; or that part from which it rises.

SPRING TIDES. The tides at the times of the new and full moon. At these times the sun and moon are in a straight line with the earth, and their joint effect in raising the waters of the ocean is a maximum, and the tides are consequently the highest. *See* TIDES.

SPRIT SAIL. This is generally a four-cornered fore-and-aft sail, supported diagonally by a piece of wood called the sprit. Ships formerly carried sails on their sprit-sail yards.

SQUA'DRON, in Military affairs, signifies a body of cavalry, averaging from one to two hundred men. In naval matters, it is applied to a detachment of ships employed on a particular expedition.

SQUALL. The Sea term for a gust of wind, or for a short temporary increase in the force of the wind.

SQUA'MA. (Lat. *a scale.*) The bracteæ of an amentum; also used occasionally for any kind of bracted or rudimentary leaf which has a scaly appearance.

SQUA'MMIPENNES. (Lat. squama; penna, *a fin.*) The name of a family of Acanthopterygious fishes, comprising those which have the dorsal and anal fins covered with scales.

SQUA'MOUS. (Lat. squama, *a scale.*) In Zoology, when a surface is covered with small scales.

SQUARE. In Geometry, a four-sided rectilineal figure, of which all the angles are right angles, and all the sides equal

SQUARE MEASURES. The squares of the lineal measures. *See* MEASURE.

SQUARE NUMBER, in Arithmetic, is the product of a number multiplied by itself. Thus, the squares of the natural numbers, 1, 2, 3, 4, 5, &c., are respectively, 1, 4, 9, 16, 25, &c. The square numbers are the first series of figurate numbers derived from the progression 1, 3, 5, 7, 9, &c., in which the common difference of the terms is 2. (*See* FIGURATE NUMBERS.) Among the properties of square numbers the following may be mentioned:—Every odd square number is of the form $8n+1$, or when divided by 8 leaves 1 for the remainder. Every even square number is of the form $4n$, or is divisible by 4. Every square number ends with one or other of the following digits, 0, 1, 4, 5, 6, 9. No number of the form $2m^2+3n^2$ can be a square.

SQUARE-RIGGED. The term for a vessel carrying *square sails*, which are extended by yards suspended horizontally, or slung by the middle.

SQUARE ROOT. In Arithmetic, the square root of any number is the number which being multiplied into itself produces the given number. Thus 12 is the square root of 144, $\frac{1}{3}$ is the square root of $\frac{1}{9}$, and ·05 the square root of ·0025. When the given number is not an exact square, the root may be found to any degree of approximation by the process for extracting the square root, which is taught in every book of common arithmetic. *See* QUADRATIC EQUATION.

SQUILL. The root of the *Scilla maritima*. Squills are imported from the Levant; they have a nauseously bitter and very acrid flavour, and are generally cut into slices and dried for pharmaceutical uses. There are two varieties, the red and the white; which, however, do not appear to differ materially in composition. In large doses squill is purgative and emetic; but it is chiefly employed in smaller doses as a powerful expectorant, and as a diuretic in combination with other remedies. Half an ounce of oxymel of squills is sometimes prescribed as an emetic in cases where the bronchiæ are much loaded with viscid mucus, and in the chronic coughs of old people.

STA'BAT MATER DOLOROSA. The first words of a celebrated Latin hymn of the church, in rhymed lines of eight syllables without metre; said to have been composed by a Franciscan monk named Jacopone, in the 14th century. It has been set to music by nearly all the greatest composers; but the best known of all their compositions is that of Pergolesi, commenced by him when nearly on his deathbed, and finished by another hand. The stabat mater is performed in the ecclesiastical services of the Roman church during Holy Week.

STACCA'TO. (It. *separated.*) In Music, a term denoting that the notes to which it is affixed are to be detached in a striking way from each other, being much like *spiccato*, which see.

STACK. Corn in the sheaf piled up in a circular or rectangular figure, brought to a point or ridge at top, and afterwards thatched to protect it from the influence of the weather, and more especially from rains. The term is also sometimes applied to hay piled up in the same manner; which, however, in most places, is called a *rick*. The foundation of a corn stack is commonly made on a platform of wood or iron, raised on props to protect it from the moisture of the soil, and also from rats and mice; in which respect stacks of corn differ from ricks of hay, which are built always on the ground.

STA'DIUM. (Gr. σταδιον.) A measure of length in use among the ancient Greeks and some other nations, the precise value of which is unknown; though there are some data from which a rough approximation to its value may be made. The most ancient measurement of an arc of the terrestrial meridian is that of Eratosthenes, and the result gave the length of the circumference of a great circle = 250,000 stadia. But the circumference of the earth's equator is known to be nearly 25,000 English miles; whence, supposing the measurement of Eratosthenes to be correct, a stadium is the tenth part of an English mile. Posidonius found by another measurement the circumference of the earth to be 240,000 stadia: on the same supposition of an accurate determination, this gives about $9\frac{1}{2}$ stadia to the English mile. But it is to be remarked, that little dependence can be placed on these ancient measurements; for Ptolemy estimated the circumference of the earth at 180,000 stadia, which is only 3-4ths of the result found by Posidonius. The stadium is, however, supposed to have been different at different places. (See Paucton, *Metrologie;* also the *Quarterly Review*, No. 5.) The best account of the stadium, and the ancient mode of measuring distances, is to be collected from the various memoirs of Danville, in the *Mém. de l'Acad. des Inscr.* vols. xxiv. xxviii. xxxvi.; and *Histoire de l'Acad.* vols. xxvii. xxxi.

STADIUM. In Ancient Architecture, an open area used for exercises by the Grecian youth. With the Romans it was much in the form of the circi, but most of the Grecian stadia were enclosed by merely an earthen mound. Vitruvius informs us that its length was much greater than its breadth; the lists were formed by a bank or terrace. Though the stadium mostly formed part of a gymnasium, it sometimes formed a separate structure, and was built at great cost and with considerable elegance; witness that on the Corinthian Isthmus mentioned by Pausanias, as well as that of Herodis Atticus at Athens, which was of large dimensions, and constructed of Pentelican marble. Besides this, mention is made by that author of several others.

STA'DTHOLDER. (Dut. stadhouder, *city-holder.*) The name formerly given to the commander-in-chief of the military forces in the republic of the United Netherlands. William I. Prince of Orange had been made governor or stadtholder of the three provinces of Holland, Zealand, and Utrecht; and during the war of Independence, he was continued in that office by the goodwill of those provinces. After his death the Earl of Leicester was declared stadtholder by the States General; while some of the separate provinces appointed Prince Maurice, son of their former governor. For a century and a half afterwards the office was conferred and withdrawn by the several provinces at many different times, although always confined to members of the house of Orange. William IV. Prince of Orange, in 1747, was the first general hereditary stadtholder; in 1794, the office ceased in the French conquest; in 1814, the present head of the house of Orange (who recently abdicated in favour of his son) was raised to the throne by the title of King William I. The power of the stadtholder varied in different provinces, and at different periods.

STAFF. In Music, the five lines and spaces between them on which music is written.

STAFF. In Architecture. *See* RUDENTURE.

STAFF. In Military affairs, those officers attached to the commander of an army to assist him in carrying his plans into execution. They consist of a quartermaster-general, adjutant-general, majors of brigade, &c. The importance of the judicious selection of a staff is ably demonstrated in the preface to *James's Military Dictionary.*

STAFF ANGLE. In Architecture, a square rod of wood standing flush with the wall on each of its sides, at the external angles of plastering on the inside of apartments, to prevent the angles thereof being broken or damaged.

STAIRS. In Architecture, steps for ascending from the lower to the upper part of a house. When these are enclosed with walls or balustrades, with landing-places for communication between the several stories of a building, the whole is called a staircase. Vitruvius makes no mention of staircases in his Treatise on Architecture; and indeed with the ancients they formed no feature in the interior, being generally on the outside of the houses. Those of which traces remain are narrow, and so inconvenient that in some cases the steps are a foot in height. In modern architecture, they are often constructed with great display of skill and magnificence, and are no small test of the skill and power of the architect. Those stairs which proceed in a right line of ascent are called *fliers;* when they wind round a solid or open *newel* they are called *winders. Mixed stairs* are such as partly wind and partly fly.

STALA'CTITES. Conical concretions of carbonate of lime attached to the roofs of calcareous caverns, and formed by the gradual dropping of water holding the carbonate in solution: from *σταλασσω, I drop.*

STALA'GMITE. Stalactical formations of carbonate of lime, found upon the floors of calcareous caverns.

STALK. In Architecture, an ornament resembling a stalk in the Corinthian capital, from which the volutes and helices spring. It is sometimes fluted.

STALL. In Architecture, a seat raised on the sides of the choir or chancel of a church, mostly appropriated to a dignitary of a cathedral or collegiate church. Sometimes stalls are placed near the high altar, for the priest and deacon or subdeacon to rest whilst the service in certain parts is carried on by the choristers. In churches of the kinds named there is generally a series of them. At St. George's Chapel, Windsor, a stall is appropriated to every Knight of the Garter after his election and installation.

STA'LLAGE. In Law, a duty paid for the liberty of setting up moveable stalls or tables, or the like, in a fair or market; due to the owner of the soil as such, to set up stalls without whose licence is trespass. When the stalls are fixed into the ground, the duty is termed *pickage.*

STALL-FEEDING. Cattle kept in stables, and tied up separately, which have their food brought to them, are said to be stall-fed. The advantages of this mode of fattening cattle are very great, both to the farmer or feeder and to the public; because much less food is wasted, and a much greater quantity of manure is produced. The disadvantages are, that more manual labour is required for cutting and carrying the food from the field to the stable; and that the flesh of the animals, for want of exercise in the latter, is not considered so wholesome or high-flavoured as that of cattle which have pastured at large. To remedy this defect of stall-feeding, the most enlightened farmers, instead of rendering their cattle fixtures by tying them up to stakes, put two or three together in small yards, with a shed at one end, in which they can take exercise, shelter, or repose, according to their inclination. By this mode an equal quantity of manure is produced with less labour, and the flesh of the cattle is reckoned wholesome. When herbage plants or grasses are cut over only two or three times in the course of a season, instead of being continually cropped by the bite of cattle during the whole summer, the amount of vegetable produce is found to be much greater, because the plant while growing perfects a sufficient number of leaves to nourish the root; and when this produce is given to cattle in racks, in stables, sheds, or small courts, much less of it is wasted than if it were eaten on the spot where it grew. Hence any given surface of cultivated land will produce a much greater quantity of butcher meat under crops to be mown than under herbage to be pastured; and stall-feeding, therefore, is one of the greatest modern improvements that has been introduced into husbandry. There can be little doubt that, with the progress of rural improvement, it will ultimately become universal; and then, and not till then, will the butcher meat of warm climates be equal to that of such climates as that of Britain. In warm climates, at present, cattle cannot be fattened by pasturing.

STA'MENS. (Lat.) The male apparatus of a flower. They are situated immediately within the petals, and consist each of a filament, the anther, and the pollen; of which the two latter are essential, and the former not. They are a modified form of the petal, and are placed next it on the inside next the centre of a flower. Independently of their physiological importance, they are much used as good marks of discrimination in systematical botany.

STAMINI'DIA. (Lat. stamen.) Those bodies which are supposed to be, in *Hepaticæ*, and other Cryptogamic plants, the equivalent of anthers in more perfect plants.

STAMP DUTIES. Duties imposed on pieces of parchment and paper on which many species of legal instruments are written; on newspapers, advertisements, cards, dice, &c. The stamp duties have been consolidated and altered by a great variety of acts of parliament; and by 4 & 5 W. 4. c. 60. the boards of stamps and taxes are united into a single one.

The manner in which the stamp duties on legal instruments are chiefly secured is by prohibiting the reception of them in evidence, unless they bear the stamp required by the law. Should the instrument, after being stamped and executed, be altered, a restamping will in certain cases be requisite: thus, a mere mistake may be altered without a stamp; but any change in the terms of a contract, or any fresh conveyance by indorsement on a former one, requires a fresh stamp. The objection to an instrument arising from the want of a stamp must be taken at the trial before the instrument is read; but it is sufficient for the purpose of evidence that the instrument when produced on the trial should be properly stamped, although it may not have been stamped when it was executed; except in cases where the commissioners of stamps are prohibited, by express enactment, from affixing in this manner a subsequent stamp. When an instrument has been lost, and it is proposed to give secondary evidence of its contents, it is necessary first to give evidence that it was duly stamped; but this fact may be presumed from circumstances: and where an instrument is withheld by an adversary after notice to produce, it is always taken as against him that it is so stamped. An unstamped instrument, though inadmissible in evidence of its contents, may yet be received in evidence for collateral purposes. Thus, in indictment for forgery of an instrument, the instrument may be produced, although unstamped; and an agreement, although unstamped, is admissible for the purpose of proving usury, &c. (See *Starkie on Evidence.*)

STA'NCHIONS. The Sea term for upright supports in general.

STAND. A Sea term, used variously; as, for example, a sail is said to *stand* well or ill. A ship is said to *stand* towards or from the shore or any object (for *to sail*). To *stand on*, to continue the course. To *stand by*, to be ready.

STA'NDARD. In Botany, the upper and erect petal of that form of corolla which is called Papilionaceous, from its fancied resemblance to a butterfly.

STANDARD. *See* BANNER, FLAG.

STA'NDARD OF MONEY. *See* MONEY.

STA'NISLAUS, SAINT. A Polish order of knighthood, founded by Stanislaus, king of Poland, in 1765; renewed by the emperor Alexander in 1815.

STA'NNARIES. (Lat. stannum, *tin.*) The stannary courts of Devon and Cornwall are courts of record for the administration of justice among the tinners. They are held before the lord warden and his substitutes. The privileges of the tinners were confirmed by 33 E. 1. The appeal from the lord warden lies to the privy council of the Prince of Wales, and thence to the sovereign.

STA'NNIC ACID. Peroxide of tin.

STA'NZA. (Ital. stanza, *station.*) In Poetry, a series or number of verses connected with each other in a poem, of which the metre is constructed of successive series similar in arrangement. The stanza, however, must be understood to form a shorter division than the classical strophe, to which this definition would be equally applicable. The term is of Italian origin, and

signifies literally a *station* or *resting place*: it is so called from terminating with a full point or pause. The *ottava rima*, which consists of six lines in alternate rhyme ended by a couplet, the lines being deca- or rather hendeca-syllabic, is the principal Italian stanza. (*See* OTTAVA RIMA.) The Spenserian stanza (which was perhaps invented by the poet from whom it derives its name, but certainly first applied by him to the construction of a regular poem) consists of eight deca-syllabic verses and an Alexandrine at the end; the first and third verses forming the first rhyme; the second, fourth, fifth, and seventh another; and the eighth and ninth a third rhyme. Lord Byron has given both to the Ottava and the Spenserian stanza in English verse a peculiar and original character.

STANZA. In Architecture, an apartment or division in a building. The series of divisions of the Vatican, for instance, are called the *stanze* of the Vatican.

STAPES. A stirrup. One of the bones of the internal ear is so called, from its shape.

STAPHYLO'MA. (Gr. σταφυλη, *a grape*.) A disease of the eyeball, in which the cornea becomes opaque and tumid, forming a white projection, sometimes resembling a grape in shape; it occasionally increases to a great extent, and requires to be removed by an operation.

STA'PLE, signified originally a public market, whither merchants were obliged to carry their goods for sale; but it is now applied to the chief commodities either grown or manufactured in any country.

STAR. (Gr. αστρον, Ger. stern.) In a popular sense, the term star is used to designate any celestial body whatever, including the planets; but in astronomy it is applied only to those self-shining bodies which are situated beyond the sphere of solar attraction, and consequently do not participate in the motions of the solar system.

One of the first results of the observation of the heavens was, that the stars maintain always the same positions relatively to each other. Hence they were called *fixed stars*, in distinction to the *planets*, or *wandering stars*, which are constantly changing their places in the firmament. The fixity of the stars is, indeed, not absolute; for modern observations have detected some changes of relative position among them; but these changes are so minute, that in general they only become sensible after the lapse of a number of years, by a comparison of positions determined with the most perfect instruments at the beginning and end of the interval. They are consequently altogether inappreciable to unassisted vision, and the discovery of their existence has not rendered a change of language necessary: astronomers still speak of the *fixed stars*.

Apparent Magnitude of the Stars. — The first circumstance which arrests the attention of the observer of the stars is the great differences of their apparent magnitudes or their relative brightness. In order to establish a gradation in this respect, and for the convenience of description and reference, astronomers divide them into classes or orders, which are called magnitudes. A few of the most brilliant are denominated stars of the *first magnitude*; those of an inferior degree of brightness are of the *second magnitude*; and so on down to the 6th or 7th, which, according to the established convention, comprehend all the stars visible to the naked eye. The gradation is, however, still continued among those which are only visible in the telescope, and magnitudes from the 8th to the 16th are familiar to those who are in the practice of using powerful instruments. It is, however, to be remarked, that this classification is not based on any photometrical determination, but is entirely arbitrary. "Of a multitude of bright objects," says Sir John Herschel, "differing, probably, intrinsically, both in size and splendour, and arranged at unequal distances from us, one must of necessity appear the brightest, one next below it, and so on. An order of succession *must* exist; and it is a matter of absolute indifference where, in that infinite progression downwards from the brightest to the invisible, we choose to draw our lines of demarcation. All this is matter of pure convention. Usage has, however, established such a convention; and although it is impossible to determine exactly, or *à priori*, where one magnitude ends and another begins, and although different observers have differed in their magnitudes, yet, on the whole, astronomers have restricted their first magnitudes to about 15 or 20 principal stars, their second to 50 or 60 next inferior, their third to about 200 yet smaller, and so on; the numbers increasing very rapidly as we descend in the scale of brightness, the whole number of stars already registered, down to the 7th magnitude inclusive, amounting to 15,000 or 20,000." (*Astronomy, Cabinet Cyclopædia*, p. 374.)

Arrangement and Nomenclature of the Stars.—In order to indicate the quarter of the heavens in which any star is situated, astronomers, in the earliest ages of the science, had recourse to the method of forming them into groups, to which they gave the name of *constellations*, or *asterisms* (*see* CONSTELLATION), and distinguished the different groups one from another by appellations borrowed in general from mythology, and suggested by vague resemblances or fanciful analogies, the origin of which it is now difficult or impossible to trace. A few of the brightest stars received particular names; some of which, conferred by the Greeks and Arabs, have been preserved, as Sirius, Rigel, Aldebaran, Arcturus, Capella, &c.; but it is obvious that this nomenclature could not be carried to any great extent. The system which has prevailed in modern times, and been generally adopted by astronomers in their charts and catalogues, was invented by Bayer, whose *Uranometria*, containing charts of all the constellations, was first published at Augsburg in 1603. It consists in distinguishing the stars belonging to each constellation by the letters of the alphabet, beginning with the brightest, which is called α. The next brightest is called β, the next in order of brightness γ, and so on; and when the letters of the Greek alphabet were exhausted, Bayer had recourse to the Roman, and then to the Italian. It is to be observed, that the order of the letters indicates only the relative brightness of stars in the same constellation, without reference to other parts of the heavens. Admitting the principle, it might have been simpler to have employed the ordinal numbers 1, 2, 3, 4, &c. for distinguishing individual stars. But great perplexity is caused by the irregular forms of the constellations, whose numerous contortions and interlacings with each other baffle the efforts of memory, and which seem, as Sir J. Herschel remarks, "to have been purposely named and delineated to cause as much confusion as possible."

Distribution of the Stars. — The stars are very irregularly distributed over the celestial sphere. In some regions spaces of considerable magnitude occur in which scarcely a single star is to be seen, while in others they are crowded together, so as to present to the unassisted eye the appearance of a confused mass of light. A great and rapid increase of number is in general perceptible as we approach the borders of the Milky Way, where they appear, when viewed through a powerful telescope, to be crowded almost beyond imagination. (*See* MILKY WAY.) Besides the general increase which takes place towards this region, there are in several parts of the heavens patches or clusters of stars, where great numbers are condensed into a very narrow space. A telescope turned upon the Pleiades shows fifty or sixty large stars crowded together within a small area, and comparatively insulated from the rest of the heavens. The constellation Coma Berenices is a similar group, though more diffused. Another occurs in the constellation Cancer, and is called Præsepe, or the Beehive, from the great number of stars it presents in the telescope. In the sword-handle of Orion there is also a group of the same kind, but in which the individual stars can only be distinguished in a telescope of considerable power; and in various parts of the heavens there are found luminous spots in which no star can be distinguished with ordinary telescopes, but which, when viewed through very powerful instruments, are found to consist of stars crowded together so as to occupy almost a definite outline. Many of them, says Sir J. Herschel, "are of an exactly round figure, and convey the complete idea of a globular space filled full of stars, insulated in the heavens, and constituting in itself a family or society apart from the rest, and subject to its own internal laws. It would be a vain task to count the stars in one of these *globular clusters*. They are not to be reckoned by hundreds; and on a rough calculation, grounded on the apparent intervals between them at the borders (where they are not seen projected on each other) and the angular diameter of the whole group, it would appear that many clusters of this description must contain at least ten or twenty thousand stars compressed and wedged together in a round space, whose angular diameter does not exceed 8 or 10 minutes; that is to say, in an area not exceeding the tenth part of that covered by the moon." (*Astronomy*, p. 400.)

Number of the Stars. — Hopeless as any attempt to count the number of the "starry host" may appear to be, it has nevertheless been sometimes made. Of the stars visible to the naked eye at any one time, the number probably does not exceed a few thousands; but in the telescope they are prodigiously multiplied. Sir W. Herschel estimates that in a zone not exceeding two degrees in breadth, but including a portion of the Milky Way, the number which passed through the field of his telescope in a single hour amounted to 50,000. On account of their irregular distribution this estimate furnishes a very imperfect datum for inferring the whole number in the sphere; but it has been supposed that not fewer than 75 millions may be visible in a good telescope. Baron Zach, indeed, was of opinion that there may be 1000 millions in the entire heavens. But it is abundantly obvious that all estimates of this sort are nothing better than fanciful conjectures; and instead of a limit being found to the number of the stars, there is an infinitely greater probability that if an observer could transport himself to the remotest visible star, he would there behold a firmament not less rich than the one he left

behind. "Every increase," says Sir J. Herschel, "in the dimensions and power of instruments, which successive improvements in optical science have attained, has brought into view multitudes innumerable of objects invisible before; so that, for any thing experience has hitherto taught us, the number of the stars may be really infinite, in the only sense in which we can assign a meaning to the word." (*Astronomy*, p. 373.)

Parallax and Distance of the Stars. — The distance of the fixed stars from the earth has in all ages been an object of interest and inquiry. The element from which the distance can be deduced is the annual parallax, or the angle subtended by the diameter of the earth's orbit at the distance of the star (*see* PARALLAX); but this distance is so great that if we except one or two instances, perhaps still doubtful, all the attempts of astronomers to determine it have hitherto been fruitless. The instance in which the observations have *most probably* shown the annual parallax to have a measurable value is that of the double star 61 Cygni, observed by Bessel at Königsberg in 1839 and 1840. The value of the parallax obtained by this celebrated astronomer was 0·3483″ (a little more than the third part of a second), from which it results that the distance of the star is 592,000 times the mean radius of the earth's orbit; a distance so enormous, that light, which is propagated with a velocity of 192,000 miles in a second, would require $9\frac{1}{4}$ years to traverse it. (*Monthly Notices of the Royal Astr. Society*, May, 1840.) Now there is every reason to believe that this is one of the nearest of the fixed stars; and it is no extravagant supposition that there may be others still visible which are a thousand times more remote. If, therefore, one of these were annihilated, some ten thousand years would elapse before its extinction could be perceived at the distance of the earth.

Proper Motions of the Stars. — On comparing the places of the stars determined by recent observations with the positions assigned to them in the older catalogues, it is found that many of them have undergone a very sensible displacement. Within the last fifty years the double star 61 Cygni, above mentioned, has moved through 4′ 23″ of right ascension; and as the motion appears to be uniform, its rate is therefore about 5·3″ annually. Another star (μ Cassiopeiæ) has an annual proper motion of 3·74″. The number of stars in which such motion has been detected, though of smaller amount than in the above instances, is very considerable. Out of 2959 stars in the catalogues of Bradley and Piazzi, Bessel found 425 having a proper motion of not less than 0·2″. The discovery of the existence of such changes in the places of the stars gives rise to some interesting speculations relative to the constitution of the universe. That the stars gravitate to each other like the bodies of the solar system is rendered certain from the phenomena of binary stars; and when we admit the prevalence of this force among them, we are led to suppose a centrifugal force to be necessary to counteract the tendency to a general collapse produced by their mutual gravitation. Hence we conclude that the proper motions must be performed in circular or elliptic orbits round some very remote centre; and as every appearance leads us to suppose the stars to be bodies of the same nature as our own sun, it becomes extremely probable that the sun with its attendant system is transported through space with a similar motion. Now the translation of the solar system would necessarily give rise to an apparent change of the positions of the stars; for in consequence of the diminution of distance, they must appear to recede from that point of the heavens towards which the sun's motion is directed, and to converge and become more condensed in the region diametrically opposite. Sir William Herschel was of opinion that this is what actually takes place, and that a general recess of the principal stars from the point occupied by ζ Herculis is already indicated by the catalogues, and consequently that the solar system is carried forward in the direction of that star. It seems, however, to be the opinion of astronomers at present, that the observations are not yet sufficient to establish the certainty of this motion; but whether the supposition shall be confirmed or not, it is evident that the proper motions which have been remarked cannot be all accounted for in this way. They appear, indeed, to be subject to no one assignable law, but to be directed to many different and even opposite points of space. It is a curious circumstance, and was first noticed by Bessel, that a large proportion of the stars which have a proper motion are double stars. In the *Memoirs of the Royal Astron. Society*, vol. ii., a list is given of all the stars whose proper motions, as determined by comparison of the observations of Bradley and Mayer with Piazzi's catalogue, exceed half a second either in right ascension or declination.

Variable and Periodic Stars. — The proper motions are not the only indications of the existence of active forces in the stellar regions. Many stars have been observed whose light appears to undergo a regular periodic increase and diminution of brightness, amounting in some instances to a complete extinction and revival. Of this kind one of the most remarkable is the star *Omicron* in the constellation Cetus, or the Whale, which has a period of about 334 days. At its greatest brightness it is a star of the second or third magnitude, and continues in this state about a fortnight, when its light begins to wane, and at the end of three months it becomes for some time invisible to the naked eye. Algol, in the constellation Perseus, appears for about 62 hours as a star of the second magnitude; its light then suddenly diminishes, and in about $3\frac{1}{2}$ hours it is reduced to the fifth magnitude: it then begins to revive, and in the space of $3\frac{1}{2}$ hours more it is restored to its original state, thus accomplishing its period in about 69 hours. The star δ Cephei has a period of about 5 days $8\frac{1}{2}$ hours, and β Lyræ one of 6 days 9 hours. A star in the breast of the Swan has a period of about 15 years, during five of which it is invisible. Various other similar instances have been remarked; and recently Sir John Herschel has pointed out α Cassiopeiæ and α Orionis (the latter of the first magnitude) as variable stars. (*Monthly Notices of the Royal Astr. Society*, May 1839, and June 1840.)

Several hypotheses have been suggested to account for these variations. Newton suggested that the stars revolve about axes of rotation, like the sun and planets; and that parts of their surfaces may be covered with spots, or be less fitted to emit light. Maupertuis supposed that their figure is not globular but flat, and that the variations of brilliancy depend on the angle made by the flat sides with the visual ray. Others, again, have imagined that the partial obscurations may be occasioned by dark bodies or planets revolving about them in regular periods.

Temporary Stars. — On examining ancient catalogues it is found that some stars formerly distinguished by their splendour have entirely disappeared, no stars being now found in the places which they are set down as having occupied. Others have suddenly shone forth with extraordinary brilliancy, and after a longer or shorter period have gradually died away, and become extinct. A phenomenon of this kind about 125 years B. C. induced Hipparchus to undertake the formation of his catalogue. In the year 389 of our era a star suddenly blazed forth near α Aquilæ, and remained for three weeks as bright as Venus, and then disappeared. But one of the most remarkable instances is that of the star which appeared in 1572, and was observed by the astronomer Tycho Brahé. It suddenly shone forth in the constellation Cassiopeia, attained a splendour equal to that of Jupiter and Venus when nearest the earth, and could be seen by the naked eye at mid-day. Its brightness gradually diminished, and at the end of sixteen months it disappeared, and has never been seen since. During the time of its visibility, its apparent place remained unchanged. All the phenomena attending it are fully described by Tycho in his work entitled *De Nova Stella Anni*, 1572. A similar phenomenon occurred in the year 1604, in the constellation Serpentarius, of which an account is given by Kepler (*De Stella Nova in Pede Serpentarii*, Pragæ, 1606). For various other instances of a similar kind, and also of stars set down in the catalogues, but which cannot now be found, the reader is referred to *Lalande's Astronomie*, tome i. p. 259.

Double and Multiple Stars. — Many of the stars which appear to the naked eye, or in telescopes of feeble power, merely as bright points, are found, when observed with high magnifying powers, to be composed of two, and some of them of three or more stars, in close juxtaposition. This appearance may arise from the circumstance of two stars being situated in nearly the same line of view; for it is evident that two stars thus placed would appear as a double star, however great the real distance between them may be. It was suggested by Galileo that the variations (if sensible) of the apparent distance between two contiguous stars would furnish a good method of determining the annual parallax; and a series of observations on double stars was undertaken by Sir William Herschel with a view to this question. The result, however, was a discovery of a very different kind; for instead of finding an alternate increase and decrease of the apparent distance between the two stars, which would be the consequence of an annual parallax, he observed in some instances a regular progressive change from year to year in one direction. By reason of the slowness of the apparent motion, a considerable interval elapsed before he was able to determine its laws; but it was explicitly announced by him in 1803 that there exist sidereal systems composed of two stars, one revolving round the other, or both about a common centre. Subsequent observations have fully confirmed this discovery; and in some instances even the ellipticity of the orbits and the periods of revolution have been determined. Some of these binary systems, as they are called, have periods of great length, and which, consequently, have been inferred from observations continued during the description of only a small part of their orbits. Thus, γ Leonis has an angular motion of about only 3-10ths of a degree in a year, and consequently requires 1200 years to complete its revolution. The star γ Virginis, which consists of two stars of

nearly the same magnitude, has a period of 629 years. The period of 61 Cygni is 452 years, and that of Castor 252 years. There are others, however, having much shorter periods, and which have already been observed through their entire orbits. The star η Coronæ, for example, has a period of little more than 43 years, and has consequenly completed nearly two revolutions since its discovery as a double star by Sir William Herschel in 1761; ζ Ursæ Majoris has a period of about $58\frac{1}{4}$ years, and 70 Ophiuchi one of about 80 years. Since the time of Sir William Herschel, the observation of double stars has been a subject of much interest in astronomy, and catalogues containing some thousands of them have been published, giving the apparent distances of the two bodies, and their angles of position, or the direction of the straight line which joins them, by comparing which with future observations their orbits and periods will become known. (Herschel and South, *Phil. Trans.* 1826; Herschel, *Memoirs of the Royal Astronom. Society*, vol. iii.; Struve, *Catalogus Stellarum Duplicium et Multiplicium*, Petropoli, 1837.)

About 40 or 50 of the double stars are already known to form binary or revolving systems; and there are others presenting phenomena still more remarkable. Struve has enumerated 52 triple stars; and systems have been observed compounded of five and even more stars, all appearing to revolve about a common centre.

Some of the binary systems afford curious instances of contrasted colours, the colour of the smaller star being frequently complementary to that of the larger. In such instances the larger star is usually of a ruddy or orange hue, and the smaller one blue or green. Sir J. Herschel thinks it probable that the colour of the small star is the effect of the brighter light of the large one; for it is a general law of optics that when the retina is under the excitement of any bright-coloured light, feebler lights for the time appear coloured with the complementary tints. This opinion seems strengthened by the fact that though insulated stars of a red colour, almost as deep as that of blood, appear in many parts of the heavens, no green or blue star (of any decided hue) has been noticed unassociated with a companion brighter than itself.

Intrinsic Light of the Stars.—On account of the distance of the stars, it is not possible to form any idea of their actual magnitude; for when viewed through good telescopes they appear simply as luminous points without any sensible disks. Their light may, however, be compared with that of any other luminous object; and Dr. Wollaston found by photometrical experiments the light of Sirius, the brightest of the fixed stars, to be to that of the sun in the ratio of 1 to 20,000,000,000. Now the proportion of light received from any luminous body being inversely as the square of its distance, it follows that the sun would require to be removed to 141,400 (the square root of the above number) times its actual distance, in order that its light should be equal to that of Sirius. But the parallax of Sirius, if sensible at all, is undoubtedly less than 1″, whence it is easily calculated that the distance of Sirius cannot be less than 200,000 times the distance of the sun from the earth: from this it follows that the light of Sirius cannot be less than the double of that emitted by the sun. Dr. Wollaston, assuming a smaller and more probable limit of the parallax, supposes the light of Sirius to be equal to that of fourteen suns. (*Phil. Trans.* 1829; *Herschel's Astronomy*, p. 380.)

The observation of the places of the stars has formed the principal business of the astronomer in all ages; for as it is to them that the motions of the planets and all the other bodies of the solar system are referred, the knowledge of their exact relative positions is the foundation of all our astronomical theories, and of all the applications of the science to the practical purposes of geography and navigation. The discovery of their proper motions could only be made after instruments and methods of observation and theory had been brought to a state of great perfection, and is consequently of recent date. For our knowledge of binary and other systems of connected stars, and, in general, of all the facts which have been brought to light respecting the physical constitution of the stars, we are chiefly indebted to the two Herschels; and so pre-eminently distinguished have been the labours and discoveries of these illustrious astronomers in this department of observation, that it is now usually called the Herschelian branch of astronomy, in contradistinction to the observation of positions which forms the business of national observatories. *See* Astronomy, Nebula.

STARBOARD. The right-hand side of a ship, looking forwards.

STARCH. (Germ. stärke.) Starch is one of the commonest proximate principles of vegetables. It is characterized by its insipidity, and by insolubility in cold water, in alcohol, and in ether. It dissolves in, or at least forms a gelatinous compound with water, heated to 175°; and this solution, even when much diluted, is rendered blue by iodine. This admirable test of the presence of starch is not effective in hot solutions; and by boiling the blue colour disappears, but returns in strong solutions as they cool. The term *starch* is commercially applied to that obtained from wheat, which for this manufacture is ground and diffused through vats of water, where it undergoes a slight fermentation, and acquires a peculiar sour smell. A part of the gluten and albumen of the grain is thus separated in the form of a viscid scum; the starch being in the form of a finely divided white powder, is gradually further separated by washing in large quantities of water, from which it is ultimately allowed to settle, and put into boxes lined with linen to drain; it is then cut into squares, which are dried first in airy chambers upon porous bricks, and afterwards rolled up in papers and *stove* dried; it is in this latter operation that the starch acquires that peculiar columnar texture and fracture, which is well exhibited on opening a paper parcel as it comes from the stove. A little *smalt* is generally added to the starch, by which it acquires a very pale blue tint, and is better adapted to conceal or cover the yellow tint acquired by worn linen. Starch may be obtained from many other grains, and from potatoes and several other esculent vegetables. *Arrow root* is the starch of the *Maranta arundinacea; sago*, of the *Sagus farinifera*, an East Indian palm tree; and *tapioca* and *cassava* of the *Jatropha manihot.* Viewed under the microscope, the varieties of starch exhibit a more or less distinct globular appearance, and are said to be made up of little spherical particles of soluble starch, enveloped in an insoluble membrane, which protects the interior from the action of cold water, but which is broken or burst by hot water. In the process of germination, and by various chemical agents, starch may be converted into a species of gum and of sugar.

Starch is charged with a duty of $3\frac{1}{4}d.$ per lb.; and its manufacture is, consequently, placed under the control of the excise. Every maker of starch for sale must take out an annual licence, which costs 5*l.* Notice must be given to the excise of the erection, and of all changes in the construction of workshops, implements, &c. used in the manufacture of starch, under a penalty of 200*l.* All starch, before it is put into any stove or place to dry, must be papered and sealed, or stamped by the officer, under a penalty of 100*l.* Any person forging or counterfeiting such stamp or seal is guilty of felony, but with the benefit of clergy. Any person knowingly selling any starch with a forged or counterfeit stamp, &c. forfeits 500*l.* No quantity of starch exceeding 28 lbs. to be removed from one place to another, unless the word *starch* be marked on the package in legible letters three inches long, under forfeiture of the package, and of the cattle and carts conveying the same. Any dealer in starch receiving any quantity exceeding 28 lbs. not marked as above, shall forfeit 200*l.* Starch-makers are to make weekly entries of the starch made by them, under a penalty of 50*l.*; and are to make payment of the duties within a week of such entry. Cockets granted for shipping starch to be carried coastwise are to express the quality, quantity, weight, the mark of the package, by whom made and sold, and to whom consigned; and if shipped without such cocket, it may be seized. No starch is to be imported, unless in packages containing at least 224 lbs. stowed openly in the hold, on pain of forfeiture, and of incurring a penalty of 50*l.* No starch is to be exported, unless the package as originally sealed or stamped by the officer be entire, and unless the officer mark the word *exportation* upon it. The duties must have been paid on all starch exported; but the exporter is entitled to an excise drawback of $3\frac{1}{4}d.$ per lb. (*Burn's Justice of the Peace*, Marriott's ed., tit. "Starch.")

STAR CHAMBER, COURT OF (Curia camera stellatæ; from the ornaments of the ceiling of the room in which at one period it sate), was originally the privy council itself, "sitting in the star chamber," and there exercising important criminal jurisdiction, and administering equitable relief. It is mentioned as early as the reign of Edward III. In the third year of Henry VII. an act was passed giving determinate criminal powers, extending chiefly to state offences and misdemeanors of a public kind, to the court of star chamber. The judges were four high officers of state, with power to join a bishop and a temporal lord of the council, and two justices of the courts of Westminster, to their number. They proceeded by bill and information without the assistance of a jury. The sittings of the privy council itself, as a criminal court, were after this gradually abandoned, and its powers transferred to the star chamber. This court continued to exercise very extensive jurisdiction, both in political matters and in private concerns, during the reigns of Henry VIII. and his successors, until it was finally dissolved by 16 Car. 1. c. 10., together with what remained of its cognate jurisdictions. (*See* Council, Privy.)

STA'RKEY'S SOAP. A compound of turpentine, or oil of turpentine, and alkali.

STA'ROST. A title under the Polish republic enjoyed by noblemen who were in possession of certain castles and domains called starostics. These were grants

of the crown, and only conferred for life, but generally renewed after the demise of a possessor to his heirs.

STA'RSTONE. A very rare variety of sapphire, which, when cut and viewed in a direction perpendicular to the axis, presents a peculiar reflection of light in the form of a star.

STA'TER. (Gr. στατηρ.) An ancient Greek measure of value. It was undoubtedly a coined piece of money at an early period. The common gold currency in the republican times of Greece consisted of staters. The Attic golden stater weighed two drachms, and is estimated at twenty silver drachms; but the value of the coin struck by different states with this denomination varied greatly.

STATES, or ESTATES. In modern European History (French états, Germ. stände), those divisions of society, professions, or classes of men, which have partaken, either directly or by representation, in the government of their country. Their number has varied in different countries. In France, and most other feudal kingdoms, there have been three estates (nobles, clergy, commonalty), members of the ancient national assemblies. Hence the well-known appellation *tiers état* (third estate) for the last. In Sweden there are at this day four: nobility, clergy, citizens, peasants. In most countries the ancient system of assemblies convoked from separate estates disappeared by the progress of absolute government in the 16th and 17th centuries; and in modern monarchical constitutions the English system of government, by king, lords, and commons, or analogous powers, has prevailed. But the states have been reconstituted of late years in some German monarchies and grand duchies, the electorate of Hesse Cassel, &c.

STATES-GENERAL. In French History, assemblies which were first called A.D. 1302, and were held occasionally from that period to the year 1614, when they were discontinued, till they were summoned again at an interesting period, viz. in the year 1789. These states-general, however, were very different from the ancient assemblies of the French nation under the kings of the first and second race. There is no point with respect to which the French antiquaries are more generally agreed than in maintaining that the states-general had no suffrage in the passing of laws, and possessed no proper jurisdiction. The whole tenor of the French history confirms this opinion. *See* ASSEMBLY, DIRECTORY.

STA'TICS. (Lat. stare, *to stand.*) The branch of Mechanics which has for its object the investigation of the conditions of equilibrating forces, or the conditions under which several forces applied to a rigid body mutually destroy each other.

There are three general principles on which the theory of equilibrium may be grounded: these are, 1. The principle of the lever; 2. The principle of the composition of forces; and 3. The principle of virtual velocities.

Principle of the Lever. — The equilibrium of a straight horizontal lever, loaded at its extremities with weights which are reciprocally proportioned to their distances from the fulcrum, was demonstrated by Archimedes (*see* LEVER); and it is easy to extend this principle to the bent lever, when the fulcrum is at the angular point, and to show that if the two arms be urged in opposite directions by two forces perpendicular to the arms, and reciprocally proportioned to their lengths, there will be equilibrium. Now, it is an axiom in statics that a force may be regarded as acting at any point whatever in the line of its direction; and hence it follows that any two forces, applied at any points whatever in a plane which is only moveable round a fixed point, and having any directions whatever in that plane, will be in equilibrium when they are to each other reciprocally as perpendiculars drawn from the fixed point to the lines of their direction; for the perpendiculars may be regarded as the arms of a bent lever having the fixed point for its fulcrum. This general principle, which is also called the *principle of moments*, suffices for the resolution of all the problems of statics, and is indeed the only one which was rigorously demonstrated previous to the discovery of the composition of forces; that is to say, previous to the publication of the *Principia* in 1687.

Composition of Forces. — The second general principle consists in this, that any two forces acting together upon the same point of a body, are equivalent to a single force represented in intensity and direction by the diagonal of a parallelogram, of which the two given forces are represented by the sides. This equivalent of the two forces is called their resultant; and as the resultant may be combined with a third force acting on the same point, and the resultant of this composition with a fourth, and so on, it follows that any number of forces applied to the same point have a single resultant, or may be replaced by a single force. (*See* FORCE.) This principle was not known to the ancients. Galileo demonstrated that a body moved by two uniform velocities, the one vertical and the other horizontal, must acquire the velocity represented by the hypothenuse of the right-angled triangle, whose sides represent respectively the two velocities. This is a particular case of the principle. Newton proved it to be true generally, and substituted the composition of forces for that of motions; and in the second corollary to the third law of motion, he shows how the laws of equilibrium may easily be deduced from it. The *Nouvelle Mécanique* of Varignon, published in 1725, contains the first complete theory of the equilibrium of forces in different machines, deduced solely from the principle of the composition of forces. The simplicity of the principle, and the facility of its application to all questions connected with equilibrium, caused it to be almost immediately adopted; and it is the basis of all the modern treatises of statics.

Virtual Velocities. — The third general principle on which the conditions of equilibrium may be made to depend consists in this, that forces acting in opposite directions destroy each other when they are inversely proportional to the velocities which they would respectively communicate to the body in the first instant of its motion, if the equilibrium were destroyed. This principle applies almost self-evidently to the conditions of equilibrium of the lever, pulley, and other simple machines. Its generality was first remarked by John Bernoulli. It has been adopted by Lagrange, as the basis of his *Mécanique Analytique;* and it has the advantage over the others of being capable of representation in a single general formula, which includes the solution of every question that can be proposed relative to the equilibrium of forces. Lagrange, however, remarks that it is not sufficiently self-evident to be erected into a primitive principle; but it may be regarded as a general expression of the laws of equilibrium deduced from the two former. *See* VIRTUAL VELOCITY.

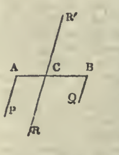
The general problem of statics may be thus enunciated: — *To find the equations of equilibrium of a body urged by any number of forces having any directions whatever in space.* We shall briefly indicate the steps by which the equations which express the conditions of equilibrium are obtained, adopting the principle of the composition of forces.

1. A force which acts on any point of a solid body may be regarded as applied at any point in the line of its direction, provided the different points of the line are invariably connected, as is the case with any two points of a rigid body. This, as already stated, may be assumed as an axiom.

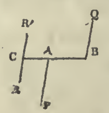
2. If a material point is urged by two forces acting in the same straight line, and in the same direction, the effect will be the same as if the point were urged in the same direction by a single force equal to their sum; and if the two forces act in opposite directions, the effect will be the same as if the two forces were replaced by a single force equal to their difference acting in the direction of the greater. The single force into which the others are compounded is called the *resultant;* and as a third force may be compounded with the resultant of two, another with the new resultant, and so on, it is obvious that any number of parallel forces acting on a point have a single resultant.

3. It has been shown in the article FORCE (p. 462.) that a force acting in any direction can always be decomposed into three others respectively parallel to three straight lines given in space, provided no two of these lines be parallel. Hence it follows that whatever be the number or the direction of the forces which act upon a solid body, they may be all replaced by three sets of parallel forces acting in given directions. We have therefore only to consider the theory of parallel forces.

4. When two parallel forces P and Q, acting in the same direction, are applied to the extremities of a rigid straight line A B, the resultant R will be equal to their sum, parallel to their common direction, and will divide the line A B into two parts in C, so that the distance of the points of application from C are reciprocally as the forces, or so that A C : C B : : Q : P. Thus, if A P and B Q be taken to represent the forces, and C R the resultant, we have C R = A P + B Q; and the two forces will be in equilibrium with a force C R′, equal to C R, and acting in the opposite direction.



5. When two parallel forces P and Q, acting in opposite directions, are applied to the extremities of a rigid straight line A B, there are two cases for consideration. If P and Q are unequal, they have a resultant which is parallel to their direction, equal to their difference, and applied at a point C in A B produced, which is such that A C : C B : : Q : P, or A C : A B : : Q : P − Q, and the two forces represented by A P and B Q will be in equilibrium with a force C R′ equal and opposite to C R. But if the two forces P and Q are equal, the point C, determined as above, is at an infinite distance, and



there is consequently no resultant. In this case, therefore, the two forces P and Q cannot make equilibrium with any single force.

The system of two equal and parallel forces applied in opposite directions at the extremities of a rigid straight line is very important in statics. For the sake of facilitating calculation, the two forces may be transferred to other points in the lines of their direction, so that the line joining the new points of application shall be perpendicular to the direction of the forces. Under this form, the system has been designated by the French mathematicians a *couple;* and its consideration has introduced great simplicity into the theory of equilibrium. We shall here state the principal properties of couples, referring for the details of demonstration to the *Elémens de Statique* of Poinsot.

6. Def.: — A couple is a system of two equal parallel forces acting in opposite directions, and applied perpendicularly to the extremities of an inflexible straight line of a given length.

7. It is obvious from the definition that the efficacy of a couple depends on two things; the intensity of the forces, and the length of the straight line or lever to the extremities of which they are applied. Now the force multiplied into the leverage is the *moment*, or the measure of the effect produced. Let the force be denoted by F, and the length of the straight line by a, then F a is the statical moment of the couple. And if there be another couple $F' a'$, such that $F : F' :: a' : a$, then $F a = F' a'$; or the statical moments of the two couples are equal, and the one may be substituted for the other without disturbing the conditions of equilibrium.

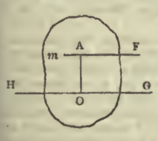
8. Any couple applied to a solid body may be transported, parallel to itself, to any position in its own plane, or in any other parallel plane; and it may be turned round through any angle in those planes without altering in any manner its effect on the body to which it is applied, provided the new points of application are invariably connected with those to which the couple was originally applied.

9. Two couples situated any where in the same plane, or in parallel planes, may be composed into a single couple equal to their sum, if they tend to turn the body in the same direction, or equal to their difference if they tend to turn it in opposite directions. Hence, by successive composition, any number of couples acting in parallel planes may be replaced by a single couple, the statical moment of which will be equal to the difference between the sum of the moments of all the couples tending to turn the body in one direction, and the sum of the moments of those which tend to turn it in the opposite.

10. Two couples situated any where in two planes which intersect each other may always be compounded into a single couple; and if we represent the moments of the two couples respectively by two straight lines, making an angle equal to that of the two planes, and complete the parallelogram, the moment of the resulting couple will be represented by the diagonal, and the plane of the resulting couple will divide the angle formed by the plane of the component couples into two parts respectively equal to the parts into which the diagonal divides the angle of the parallelogram. From this it is obvious that by successive composition any number whatever of couples, applied in any manner to a solid body, may be replaced by a single couple.

11. Reciprocally, any couple may always be resolved into two others situated in given planes, provided these planes and the plane of the proposed couple meet in the same or in parallel straight lines.

12. From the principles above stated, we draw this important conclusion, — viz. that when a solid body is urged by any number of forces having any directions whatever, the whole may be reduced to one force and to one couple. For let m be one of the points of a solid body, and conceive a force F represented in intensity and direction by the straight line m F to be applied at m. Take O any point whatever in the solid body or invariably connected with it, and draw O A perpendicular to m F, and conceive the force F to be applied at A in the same direction m F. Now suppose another force G represented by O G, equal and parallel to m F, to be applied at O, and let a third force H represented by O H, equal to O G, but acting in the opposite direction, be also applied at O. These two auxiliary forces will not alter the statical condition of the body, because the one exactly destroys the effect of the other. But the system of three forces F, G, H may now be conceived as consisting of a single force G applied at O, and of a couple formed by the two forces F and H applied at the extremities of the lever O A. Let O A be denoted by a, then the statical moment of this couple is F a; and by

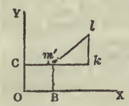


(9.) we may conceive it to be moved in its own plane until the centre of the arm O A coincides with the point O.

In like manner, if the other points m' m'' &c. of the solid body be respectively urged by forces F' F'', &c., acting in any directions whatever, each of these forces may be replaced by a single force acting at O, and by a couple having its centre at O. Now (2.) all the force acting at O will have a single resultant R applied at the same point, and all the couples having their centre at O may be compounded into a single couple, which has its centre at the same point (9). Therefore, finally, the whole of the forces acting on the solid body may be reduced to one force and to one couple; and in order that the body may remain at rest, it is necessary that the efforts of the resulting force and the resulting couple be severally destroyed. It is to be observed, that the resultant R cannot destroy the couple, or be in equilibrium with it; and, in general, the resultant and the couple will be situated in different planes.

From this it appears that the conditions necessary for the equilibrium of a body urged by a number of forces are these: — 1. That the resultant of all the forces at the point O be nothing; and 2. That the moment of the couple be nothing. When the first of these conditions is satisfied, there can be no progressive motion; and when the second is satisfied, there can be no rotatory motion about an axis. In order to express these conditions by equations, an expression for the single resultant, and an expression for the single couple, must be deduced from the conditions of the proposed problem, and the results severally made equal to nothing. We shall now show the general forms of these expressions, and for simplicity we shall first suppose all the forces to act in the same plane.

Let there be any number of forces F', F'', F''', &c. applied respectively at the points m', m'', m''', &c. of a system of points invariably connected; and suppose all the points to be in one plane, and all the forces to act in the same plane, but to have any directions whatever in that plane. From a point O taken arbitrarily in the plane draw the rectangular axes O X, O Y; then, whatever the direction of the force F', it may be resolved into two forces respectively parallel to these axes. Let the force F' be represented in intensity and direction by the line $m' l$, and let $X' = m' k$ be its component parallel to the axis O X, and $Y' = k l$ its component parallel to O Y. In like manner let X'' and Y'' be the components of a second force F'' resolved in the same manner, X''', Y''' those of a third F''', and so on; then, instead of the system of forces F', F'', F''', &c., we shall have two groups of parallel forces, namely, X', X'', X''', &c. parallel to O X, and Y', Y'', Y''', &c. parallel to O Y.



Now if x' and y' be the co-ordinates of the point m', so that $x' = $ O B, and $y' = $ O C (m' B and m' C being respectively perpendicular to O X and O Y); then (12.) the force X' may be replaced by an equal force applied at O, and by a couple whose statical moment is $X' \times$ O C $= X' y'$. In like manner the force Y' may be replaced by an equal force applied at O, and by a couple whose statical moment is $Y' \times$ O B $= Y' x'$. Each of the remaining forces X'', X''', &c. Y'', Y''', &c. may evidently be replaced in a similar manner. But it is evident that the group of forces X', X'', X''', &c. applied at O, may be represented by a single force X equal to their sum (those which fall to the right of the axis O Y being considered as positive, and those which fall in the opposite direction as negative), and those of the group Y', Y'', Y''', &c. by a single force Y (having due regard to the signs), and the first condition of equilibrium requires that we have $X = 0$, $Y = 0$ (for the resultant of X and Y can only be nothing when these quantities are severally $= 0$); that is to say, we must have the two following equations: —

$$\left.\begin{array}{l} X' + X'' + X''' + \&c. = 0 \\ Y' + Y'' + Y''' + \&c. = 0 \end{array}\right\} \ldots (a)$$

With respect to the two sets of couples $X' y'$, $X'' y''$, &c., $Y' x'$, $Y'' x''$, &c., since they are all situated in the same plane, it follows from the principle stated in (9.) that they may all be compounded into a single couple whose statical moment is equal to the sum of the statical moments of the component couples; and since the second condition of equilibrium requires that the moment of this resultant couple be nothing, the following equation must be satisfied: —

$$X' y' + X'' y'' + \&c. - Y' x' - Y' x'' - \&c. = 0 \ldots (b)$$

The effort exerted by each of these separate couples is to turn the system round an axis passing through the point O, and perpendicular to the plane X O Y; and the sum of the efforts being nothing, there is consequently no rotatory motion communicated.

The equations which have now been obtained for the equilibrium of a system of forces all acting in the same plane are easily rendered general. Let F', F'', F''', &c.

be the forces, having any directions whatever in space, applied to the points of a solid body; through a point O in the body, or invariably connected with it, draw three rectangular axes, O X, O Y, and O Z; and let each of the forces F′ be resolved into three others parallel to those axes, and denoted respectively by X′, Y′, Z′; then the first condition of equilibrium obviously requires the three equations,

$$\left.\begin{array}{l} X' + X'' + X''' + \&c. = 0 \\ Y' + Y'' + Y''' + \&c. = 0 \\ Z' + Z'' + Z''' + \&c. = 0 \end{array}\right\} \ldots (c)$$

With respect to the couples formed by transporting the resolved forces from their points of application to the point O, it is manifest that as the directions of the forces are now in planes parallel to three rectangular planes, X O Y, X O Z, and Y O Z, the couples may all be transferred to those three planes; therefore, by the same reasoning as above, it is easy to see that in each plane there will be two sets of couples tending to turn the body about an axis perpendicular to that plane. Thus, in the plane X O Y, there will be, as before, the two sets of couples $X'y'$, $X''y''$, &c., $Y'x'$, $Y''x''$, &c.; and, similarly, in the plane X O Z there will be the two sets $X'z'$, $X''z''$, &c., $Z'x'$, $Z''x''$, &c.; and in the plane Y O Z the two sets $Y'z'$, $Y''z''$, &c., $Z'y'$, $Z''y''$, &c. Now, supposing all these couples compounded into one, it is manifest that the moment of this resulting couple can only be nothing when the sums of the moments of the couples in each plane are respectively nothing: hence we have this second set of equations,

$$\left.\begin{array}{l} X'y' + X''y'' + \&c. - Y'x' - Y''x'' \&c. = 0 \\ Y'z' + Y''z'' + \&c. - Z'y' - Z''y'' \&c. = 0 \\ Z'x' + Z''x'' + \&c. - X'z' - X''z'' \&c. = 0 \end{array}\right\} \ldots (d)$$

These two systems of equations (c) and (d) contain the conditions necessary for the equilibrium of any solid body. When the first system (c) is satisfied, there can be no progressive motion; and when the system (d) is satisfied, there can be no rotation about an axis.

These two systems of equations are usually given under a different form. Let α', β', γ', be the three angles which the direction of the force F′ make with lines parallel to the three axes O X, O Y, O Z; we shall then have for the components of the force F′,

$$X' = F' \cos. \alpha',\ Y' = F' \cos. \beta',\ Z' = F' \cos. \gamma'.$$

Denoting the analogous angles in respect of the force F″ by α'', β'', γ'', we shall have similar expressions for the components of that force; and so on. Hence the six equations (c) and (d) become

$$\left.\begin{array}{l} F' \cos. \alpha' + F'' \cos. \alpha'' + \&c. = 0 \\ F' \cos. \beta' + F'' \cos. \beta'' + \&c. = 0 \\ F' \cos. \gamma' + F'' \cos. \gamma'' + \&c. = 0 \end{array}\right\} \ldots (c')$$

$$\left.\begin{array}{l} F'(y' \cos. \alpha' - x' \cos. \beta') + F''(y'' \cos. \alpha'' - x'' \\ \quad \cos. \beta'') + \&c. = 0 \\ F'(z' \cos. \beta' - y' \cos. \gamma') + F''(z'' \cos. \beta'' - y'' \\ \quad \cos. \gamma'') + \&c. = 0 \\ F'(x' \cos. \gamma' - z' \cos. \alpha') + F''(x'' \cos. \gamma'' - z'' \\ \quad \cos. \alpha'') + \&c. = 0 \end{array}\right\} (d')$$

Our limits will only permit of our giving a general indication of the manner in which the above equations are applied to the solution of particular problems.

1. If the body is retained by a fixed point, we have only to assume the fixed point as that in respect of which the preceding transformations are made. The effort of the resultant of the different forces will then be annihilated by the resistance of the fixed point, and consequently there will be equilibrium if the resultant couple is nothing, or if the three equations (d′) are satisfied.

2. If the body is retained by two fixed points, the line which joins them will constitute a fixed axis in the body. On taking the point O any where on the axis, the resultant of the forces applied at O will again be destroyed by the resistance of the axis; but in order that equilibrium may take place, it is not now necessary that the resulting couple be nothing,—it is sufficient that it be situated in any plane which contains the axis; for when this condition is fulfilled its arm coincides with the axis and is fixed, and consequently the effect of the forces applied at its extremities will be annihilated.

3. Lastly, if the body, in other respects free, be subjected to touch an invariable plane, it is not necessary for equilibrium that the equations (c′) be satisfied; it will be sufficient if the resultant of the forces be perpendicular to the plane, provided it also fall within the interior of the space which limits the points of contact of the body with the plane, for in this case it will be destroyed by the plane's resistance. The second system of equations (d′) must, however, be satisfied; since the resistance of the plane can only generate a normal resistance, which, therefore, is incapable of destroying the action of the couple.

Of all the forces which act upon bodies, that which most frequently comes under our observation is terrestrial gravity, under the influence of which all bodies, when unsupported, fall to the ground in vertical lines. A solid body acted upon by gravity presents the case of an infinite number of connected points urged by parallel forces; for though gravity is directed towards the centre of the earth, yet, by reason of the great magnitude of the earth in comparison of such bodies as usually come under consideration, the direction of the forces acting on the different points may all be regarded as parallel. All these forces have therefore a single resultant, which, in respect of every particular body, passes through a given point, called the centre of gravity. The determination of the centres of gravity of different bodies, and of their various properties, consequently forms a considerable portion of every treatise on statics. For the general formulæ, see CENTRE OF GRAVITY. (See Poinsot, *Elémens de Statique;* Biot, *Notions de Statique;* Poisson, *Traité de Mécanique;* Lagrange, *Mécanique Analytique; Whewell's Mechanics;* and the references under the term MECHANICS.)

STA′TION. (Lat. stare, *to stand.*) In Astronomy, a planet is said to be at its *station*, or to be *stationary*, when its motion in right ascension ceases, or its apparent place in the ecliptic remains for a few days unaltered. The real motions of the planets are always in the same direction from west to east; but owing to the motion of the earth from which they are seen, their *apparent* motions, though generally from west to east, or direct, are sometimes from east to west, or retrograde, and in changing from one of these directions to the other the planet appears for some short time to stand still. The distance of the earth and of a planet from the sun being given, and also their periodic times, the determination of the arc of retrogradation, or the times at which the planet will appear stationary, is an easy problem; but to the ancient astronomers, who were unacquainted with the relative distances of the planets, and who, moreover, supposed the earth to be the centre of motion, the phenomena of the stations and retrogradations occasioned great embarrassment, and the principal object of the various systems which were propounded previous to that of Copernicus was to give a satisfactory explanation of them. *See* EPICYCLE, PLANET.

STATION, in Surveying, is the place selected for planting the instrument with which an angle is to be measured.

STATION, in the Church of Rome, is applied to certain churches in which indulgences are granted on certain days.

STATION, is applied to those resting-places on railways at which a halt is made for the purpose of receiving or letting down passengers or goods. The last stations on a railroad are called the *termini*.

STATIONARY ENGINE, in contradistinction to "Locomotive Engine," expresses a steam engine in a fixed position, which draws loads on a railway by a rope or other means of communication extended from the *station* of the engine along the line of road.

On railways worked by locomotive engines, inclined planes sometimes are constructed of an acclivity too steep to be worked with advantage by these machines: such a plane occurs on the London and Birmingham railway, between the passenger station at Euston Square and the depôt and station for goods at Camden Town. Similar inclined planes are constructed on the Liverpool and Manchester railway, between the quay at Liverpool and the station at Edge Hill, and between the passenger station at Lime Street and the same place. In these cases a stationary engine is placed at the summit of the inclined plane, by the power of which acting on a rope carried along the plane the trains of carriages and waggons are drawn to the summit.

But it is not only on planes whose acclivity forbids the advantageous application of locomotive engines that stationary engines are used as a moving power on railways. In some situations, where a line of railway is sufficiently level, they are applied in preference to locomotive power. Thus the railway extending from the India House in London to Blackwall, whose acclivities do not exceed sixteen feet per mile, is worked throughout its entire length by stationary power.

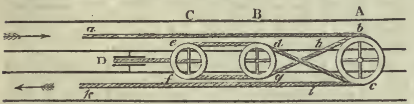
When a line of railway is to be worked by stationary engines the whole line is resolved into a succession of stages of certain lengths, at the end of each of which a stationary steam engine is placed; or, more generally, *two* such engines are provided, in order that the occasional suspension of one for the purpose of repairs may not interrupt the traffic of the road. The power of these engines is applied to give motion to a drum, or cylinder, or wheel, on which a rope is wound. This rope extends along the road, being supported at short intervals on iron sheaves or pulleys, by which its friction and consequent wear and resistance are diminished.

There are several methods by which the stationary engine is made to draw the train by a rope.

The plan adopted by Mr. Stephenson to draw the trains of goods from the quay at Liverpool to the station at Edge Hill, up an inclined plane of about a mile in length, is by an *endless rope*. At the foot of the machine a wheel is laid down in a horizontal position, revolving on a ver-

tical axis, having a groove on its circumference of a proper magnitude to receive the rope. The diameter of this wheel is equal to the distance between the centres of the two lines of rails; so that when the rope is extended between each line it will fall into the groove at the ends of that diameter of the wheel which is at right angles to the line of road. Thus, the rope being brought round the groove of the wheel for half its circumference, is carried up each line of rails midway between the rails.

At the summit of the plane, a similar wheel is similarly placed, round which the rope is conducted; but, instead of being merely carried half round this wheel, it is brought round two other wheels of less diameter, by means of which the necessary tension is given to it. Let A repre-



sent the great wheel at the top of the plane, and let *a b* represent the rope passing up the plane between one line of rails and falling into the groove of the wheel at *b*. It is carried round the wheel A to *c*, and thence passes diagonally to *d*, where it falls into the groove of a smaller wheel B, from whence it is carried to *e* and half round another wheel C, equal to B; and from *f* it is conducted to *g*, where it falls again into the groove of the wheel B, from whence it passes diagonally to *h*, and half round a second groove in the great wheel A to *i k*, from whence it is carried down the other line between the rails.

The steam engine is thrown into connection with the axle of the wheel, to which it imparts continued revolution. The adhesion of the rope to the grooves makes this motion cause the rope to be drawn in the direction of the arrows. Any train of carriage, therefore, attached to the rope *a b* would be drawn in one direction, and a train attached to *i k* would be drawn in the other direction. The tension of the rope is regulated by a weight suspended by a rope passing over a vertical wheel D, and attached to the axle of the wheel C. This weight hangs in a pit, and continually draws the wheel C from the wheel D. By this means, however the rope may vary its length by moisture or other hygrometric causes, it will necessarily have the same tension.

The new tunnel at Liverpool, extending from the engine station at Edge Hill to the passenger station at Lime Street, is differently worked, but also by an endless rope. The distance from the Lime Street station being 2200 yards, a horizontal shaft is extended across the whole width of the two lines of railway at Edge Hill. The extremities of this shaft are continued on either side into two buildings, where stationary engines are erected. A motion of revolution may be given to the shaft by either of those engines separately, or by both of them simultaneously. Upon the shaft, and in the centre of one of the lines of railway, a grooved wheel, 19½ feet in diameter, is fixed with its plane vertical. The rope, which constantly ascends the plane between the rails of the line appropriated to ascending trains, passes over this wheel, and, being brought under it, is returned nearly to the point where it first comes upon it. It is there conducted into the groove of another wheel 4 feet in diameter, placed in front of the greater wheel. By this arrangement the rope embraces nearly the whole circumference of the greater wheel, and an adhesion is obtained sufficient to draw a load of one hundred tons up the plane. After the rope passes over the smaller wheel, it is carried round a horizontal wheel placed upon a carriage running backwards and forwards upon a railway, which wheel is drawn by a weight similar to that described in the preceding case, by which a uniform tension is given to the rope. After passing round this horizontal wheel, the rope is then directed to the centre of the other line of railway by two other horizontal wheels, and, after passing down the plane, is conducted by two other horizontal wheels at Lime Street into the centre of the ascending line, along which it is conducted, as already described, to the large shaft wheel at the top of the plane.

By either of the contrivances here described a railway of any extent may be worked by stationary engines driving endless ropes; and as the rope is at the same time moving in contrary directions along the two lines of railway, trains may be drawn by the same engine at the same time in contrary directions. In case of such a rope being applied to an inclined plane, the weight of the descending train would act upon the ascending train, leaving the moving power to act against the difference of their weights only. If, in such a case, the descending load were greater than the ascending load, the latter would not only descend by its gravity without any moving power, but would draw the ascending load up. A plane worked in this way without an engine is called a self-acting plane. Railways composed of self-acting planes are very frequent in mining districts, where the level at which the mineral product is obtained is much more elevated than that at which it is shipped. The weight of the mineral itself is, in such cases, used as the moving power, the loaded waggons in their descent drawing the empty waggons in the contrary direction.

When an endless rope is not used, the power of the engine is applied to a drum or cylinder, called a rope-roll, on which the rope is coiled. In such cases, the rope being carried along the line of rails, has its extremity attached to the train to be drawn; and the engine, as it works, turns the rope-roll on which the rope is gradually coiled, and the train is thus drawn towards the engine. When the train has arrived there, the whole of the rope will be coiled on the rope-roll. In order to move the train in the other direction, a similar engine is placed at the other extremity of the railway along which the train is moved; and the train is drawn back by the other engine in the same manner. But, in order to unroll the rope from each rope-roll, the train, in returning, is made to draw the rope after it. Thus the two engines reciprocally draw the train backwards and forwards between them; each engine, while it draws the train in one direction, unrolling the rope from the rope-roll of the other.

There are various other expedients that have been suggested and practised for working railways by *stationary* engines and ropes, but all of them partake more or less of the principle of one or other of these here described. The speed attainable by such means was formerly very limited; but the application of ropes and the machinery connected with them has been much improved, and, if it were otherwise desirable, a line of railway could now be worked at an average speed of from fifteen to twenty miles an hour by a series of stationary engines and ropes. Nor would it be necessary in passing each station to stop the train, expedients being devised by which the train may be transferred from one rope to another without stopping it.

STA'TIONERY. The name given to all the materials employed in the art of writing, but more especially to those of pens, ink, and paper. The term *stationery* is derived from the business of booksellers having been anciently carried on entirely in stalls, or *stations*. The Stationery Office in London is the medium through which all government offices, both at home and abroad, are supplied with writing materials; and at the same time it contracts for the printing of all reports and other matters laid before the House of Commons, &c. It consists of a comptroller, a storekeeper, and about thirty clerks and other subordinate officers; and has a branch establishment at Dublin.

STATION POINTER. An instrument used in maritime surveying, for expeditiously laying down on a chart the position of a place from which the angles subtended by three distant objects, whose positions are known, have been observed. It consists of three scales, which move about a common centre, two of them carrying each a divided circular arc, and the third two verniers adapted to the arcs, by means of which the scales can be opened so as to form two angles of any inclination. Suppose the angles of the scales to be made equal to the two measured angles, and the instrument to be laid on the chart, so that the edges of the three scales coincide with the positions of the observed objects, the centre marks the position of the spot from which the objects were observed. (See *Simms's Treatise on Mathematical Instruments*, p. 98.)

STA'TIONS. In Ecclesiastical Antiquities (from the Roman statio, *a soldier keeping guard*). The weekly fasts of Wednesdays and Fridays. These were omitted between Easter and Whitsuntide. They terminated at three in the afternoon; hence sometimes called *semi-jejunia*. Saturday was made a station day by the council of Elvira; which, it is said, led to the gradual neglect of the Wednesday station in the Western church. (*Riddle's Christian Antiquities*, 624.)

STATI'STICS. (Lat. status, *state, condition*.) The name given to the science which exhibits the state or condition of a country or nation, principally in relation to its extent, population, industry, wealth, and power.

By a statistical account of a country, we mean a work describing its situation and extent; its natural and acquired capacities of production; the quantity and value of the various articles of utility and convenience existing and annually produced in it; the number and classes of its inhabitants, with their respective incomes; its institutions for the government, improvement, defence, and maintenance of the population; with a variety of subsidiary statements and details. A science embracing so great a variety of objects is not easily defined or limited; nor is it possible to draw any distinct line of demarcation between what should be left out of statistical works, and what should be included in them. Much must always depend on the object in view, and on the good sense and discrimination of the author. Statistics has many features in common with geography and politics, and embraces that sort of mongrel science

that has been called political arithmetic. Some authors, and, among others, the economist M. Say, contend that any description, however brief, of the territory of a country is foreign to statistics, and belongs exclusively to physical geography. But this is evidently a most erroneous statement. How can we acquire any accurate or comprehensive knowledge of the capacities of production enjoyed by a country, if we be unacquainted with its situation, soil, climate, and native products, and with its facilities for bringing them to market and exchanging them with others? So far from being alien to, this knowledge lies at the very foundation of the science; and any work which should omit it, however well it might be executed, would have no claim to be considered as a complete statistical work. Those topographical details which are essential in a geographical work would, however, be totally out of place in one devoted to statistics. One of the principal objects of the latter is to exhibit the means and sources of the national wealth, its amount and distribution; and these would not be in any respect promoted by indulging in topographical details. Hence, in statistical works, a short notice of the principal divisions of the country, with reference especially to its climate, soil, native products, agriculture, including the method of holding and occupying lands, manufactures, and population, is generally sufficient. This much, however, cannot be dispensed with. It is the foundation on which all the rest of the building is to stand; and the completeness of the other, and more elevated parts, will generally depend more on the compactness and solidity of this than on any thing else.

Opinions differ as widely as to the mode in which statistical treatises should be drawn up, as with respect to the topics they should embrace. Some contend that their object is limited to an exposition of the state of a country, province, or place, at some given period; and that, consequently, all historical and theoretical discussions should be rigidly excluded. The Germans, who are supposed to be the great authorities in statistical matters, mostly compose their works on this plan; but it, notwithstanding, appears to us to be radically objectionable, and to be calculated to deprive the science of all that is most interesting and instructive. Nor need we travel beyond the sphere of German statistical works for ample proof of what is now stated. They are, in fact, with few exceptions, the most worthless rubbish imaginable. We have accounts, sometimes accurate and sometimes not, but usually put forward with equal confidence, of a variety of minute facts; but as we have no explanation of the circumstances under which they originated, they communicate, even when accurate, little useful information: and it would not be more idle to attempt to form any notion of St. Peter's or St. Paul's from an account of the number of tons of stone, brick, and mortar in each, than it would be to attempt to form any opinion of the state of Prussia, Austria, or any other German state, from the details respecting it supplied by German statistical writers. They tell us, for example, that so many looms were at work in such a town or place at such a time; but the chances are, not a word will be said as to whether the number of looms was increasing or diminishing; and supposing that were stated, it is all but certain that not a word will be said explanatory of the causes by which this result has been brought about, though this be, in fact, of ten times more importance than anything else. This species of statistics presents us with a skeleton, instead of a living animated body. It is of importance, no doubt, to know the amount of population, the sum paid in taxes, the rate of wages, &c. in a country or district at any given period; but it is only by comparing these statements with others of the same sort, applying to different epochs, that we learn whether such country be advancing or retrograding: and it is only by comparing details peculiar to one country with those peculiar to another, that we learn in what respects they agree and differ, and that the attention of the politician and economist is called to those circumstances that retard the progress of the one, and accelerate that of the other. Those who make a parade of subdivisions would call this *comparative statistics*, and would contend that it should not be mixed up with descriptive statistics. But to be really good, and possessed of interest enough to make it be read, a work must embrace both. They should not be so intermixed as to create confusion; but unless they be combined in due proportions, the principles on which the comparisons are made expounded, and the circumstances that produce the discrepancies pointed out, and their influence correctly appreciated, no details, however accurate, can be of much value. It is the easiest thing possible to pile figures on figures; but unless deduced from correct data, they serve only to mislead; and they do this the more easily, that they have a scientific air about them, and that most people shrink from the irksome task of examining whether tabular statements be correct or not. There is nothing, indeed, about which one should be so sceptical as the greater number of what are called statistical facts and details, or with respect to which a sound and searching criticism is so necessary. The reader would do well generally to look with suspicion and distrust on most statements, how imposing soever they may appear, unless he be informed of the sources whence they have been derived, and of the principles on and the mode in which they have been compiled.

It would be easy to illustrate what has now been said by references to the statements in parliamentary and other official documents, many of which are altogether false; while many more, from the conditions to which they apply not being clearly set forth, are, though not absolutely incorrect, fitted only to mislead.

Perhaps the least valuable book ever published on any important subject was that of Dr. Colquhoun *On the Wealth and Resources of the British Empire*. It is, from beginning to end, a tissue of extravagant hypotheses, exaggeration, and absurdity. Nothing was too difficult for this intrepid calculator. Under his transforming hand every thing was reduced to figures; and matters as to which it is impossible to obtain any certain information, and of which he knew nothing, were set down as if they had been ascertained with absolute precision! And yet the most extravagant of his statements were for a while regarded as well-established truths. The book obtained an extensive circulation; it was translated into German, and the German doctors continue to refer to it as if its authenticity were alike unquestioned and unquestionable.

In justice, however, to the German writers on statistics, it should be stated that the circumstances under which they are placed do not really admit of their publishing the best class of works. In Prussia, Austria, and most German states, the press is subject to a rigorous censorship; and no statements of a political kind are allowed to be published that might give offence to government, or that would be likely to call the attention of the reader to the defects in the organization of the state. This sufficiently accounts for the absence of such discussions in German works, and their anti-critical character. But this certainly is no reason why the writers of other nations, not laid under any restraints, should adopt such emasculated works as models for their treatises.

Indeed it would seem to be considered by some writers that every thing in statistics may be estimated in figures, and exhibited in tabular statements! But the truth is, that but a few of the more prominent facts, in regard to the situation of any great country, can be so exhibited. A grand object in every good statistical work should be, not merely to state what is, but *why it is*; to trace and exhibit causes as well as effects; to show how advantageous results may be best brought about, and how those of an opposite character may be best avoided.

It may be said, perhaps, that this would encroach on the province of the politician and political economist. But, in our estimation, a certain admixture of politics and political economy is indispensable to statistics. Without such admixture, most statistical works are little better than worthless: if they are to be excluded, a good almanac may be taken as the model of a good statistical work.

Arthur Young, in his *Travels in France*, Townsend, in his *Travels in Spain*, and Volney, in his *Syria and Egypt*, indulge largely in discussions that depend more or less on politics and political economy. But, nevertheless, no one can doubt that the books in question belong to the class of travels, of which, indeed, they are among the very best specimens. And why should it be otherwise with statistical works? If their writers know what they are about, they will use political science not to supersede, but to illustrate, explain, and give utility to their statistical details.

A really good statistical work can only be compiled by a writer who to great talent and good sense adds the most extensive information, and hence the extreme rarity of such works; but, when properly executed, they are alike instructive and interesting. *Est enim cognitio reipublicæ et privato homini et publico utilissima et maxime necessaria, atque scientiam illam, qua duce cognitionem reipublicæ nobis comparamus, imprimis dignam esse, quam studiosius colamus et prosequamur, non est, quod jure negare vel adeo dubitare possimus.* (Mone, *Hist. Statisticæ*, p. 4.)

We subjoin a few of such of the more interesting particulars in the statistics of the United Kingdom, and of Europe generally, as may be exhibited in a tabular form. The details are mostly derived from official returns.

STATISTICS.

STA'TUARY. (From statue.) The art of carving or otherwise forming statues.

STATUE. (Lat. statua, from sto, *I stand.*) In Sculpture, a representation in relief in some solid substance, as marble or bronze, or in some apparently solid substance, of a man or other animal. There are various species of statues: — 1. Those smaller than nature. 2. Those of the same size as nature. 3. Those larger than nature. 4. Those that are three or more times larger than nature, and are called *colossal*. The first were by the ancients confined to men and gods generally. The second were confined to the representation of men celebrated for their learning and talents, who had rendered service to the state, and were executed at the public expense. The third were confined to kings, emperors, and, when more than twice the size of nature, to heroes. The fourth species were confined to statues of the gods, or of kings and emperors represented under the form of gods. *Equestrian statues* are those in which the figure is seated on a horse. *See* SCULPTURE.

STA'TUS QUO. In Politics, a treaty between two or more belligerents, which leaves each party in possession of the same territories, fortresses, &c. as it occupied before hostilities broke out, is said to leave them "in statu quo ante bellum," in the same state as before the war.

STA'TUTE. (Lat. statuo, *I establish.*) An act of parliament made by the king by and with the advice of the lords and commons. But some ancient statutes are in the form of charters or ordinances, proceeding from the crown, and in which the consent of the lords and commons is not expressed. 1. As to the time from which statutes run, if no time was expressed for the operation of a statute to commence, it was of force anciently from the first day of the session, and consequently had a retrospective operation. By 33 G. 3. c. 13. it now has force from the day on which it receives the royal assent. 2. Statutes are divided into public and private; a distinction which rests rather on conventional usage and difference in the formalities of passing them, than on any principle; and public acts themselves may be either local or general. There may be a private clause in a general act. Statutes are also said to be *declaratory* of the law as it stood at their passing; *remedial*, to correct defects in the common law, subdivided into *enlarging* and *restraining;* and *penal*, imposing prohibitions and penalties. But these, again, are rather distinctions of an arbitrary character than of any legal effect, although some legal maxims have been founded on them; *e. g.* that penal statutes, or clauses in statutes, are to be construed strictly, remedial statutes liberally, &c. A few other rules laid down by learned authorities in the construction of statutes are, — that they are to be construed out of the words themselves, according to the true intent of the makers; that when the words of a statute are doubtful, general usage may be called in to explain them; that the purview of the whole act is to be considered, and not particular words or clauses only; that doubtful words are to be construed with reference to the object of the act; that the *preamble*, or recital at the commencement, is to be considered, as it generally indicates the evil which it was meant to remedy, and consequently affords an insight into the meaning of the framers; that repeal of former statutes by implication shall not be favoured, &c. Statutes are numbered according to rather an inconvenient arrangement: the entire acts of one session are considered as forming two collections or volumes, one of public and one of private acts; each act forming a distinct "chapter," and subdivided into sections.

STAUROLITE. (Gr. σταυρος, *a cross*, and λιθος, *a stone.*) The mineral called *cross-stone*, *harmotome*, and *Andreasbergolite*. It is a silicate of baryta and alumina, with traces of lime and potash, and forms small quadrangular prisms crossing each other: the most characteristic specimens are from Andreasberg, in the Hartz.

STAUROTIDE. (Gr. σταυρος, *a cross*, and ειδος, *form.*) A name given by Haüy, and other mineralogists, to the prismatic garnet, or *grenatite*. It occurs in four and six-sided prisms, sometimes crossing each other at right angles. It is a silicate of alumina and lime, with the oxides of iron and manganese. It occurs in primary rocks, and is distinguished from garnet by its form and difficult fusibility.

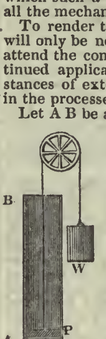
STAY. A strong rope from the mast head, leading forward to support it from falling aft. It takes the name of the mast, as the fore stay, main-topmast stay, &c. *To stay*, means to tack. To be *in stays*, is to be in the act of tacking. To *miss stays*, signifies to fail in attempting to tack.

STEAM. The elastic fluid into which water is converted by the continued application of heat.

All liquids whatever, when exposed to a sufficiently high temperature, are converted into vapour. The mechanical properties of vapour are similar to those of gases in general. The property which is most important to be considered, in the case of steam, is the elastic pressure. When a vapour or gas is contained in a close vessel, the inner surface of the vessel will sustain a pressure arising from the *elasticity* of the fluid. This pressure is produced by the mutual repulsion of the particles, which gives them a tendency to fly asunder, and causes the mass of the fluid to exert a force tending to burst any vessel within which it is confined. This pressure is uniformly diffused over every part of the surface of the vessel in which such a fluid is contained: it is to this quality that all the mechanical power of steam is due.

To render the chief properties of steam intelligible, it will only be necessary to explain the phenomena which attend the conversion of water into vapour by the continued application of heat, under the various circumstances of external pressure which present themselves in the processes of nature and art.

Let A B be a tube or cylinder, the magnitude of whose base is a square inch, and let a piston P move steam-tight in it; let it be imagined that under this piston, in the bottom of the cylinder, there is an inch depth of water, which will therefore be in quantity a cubic inch; let the piston be counterbalanced by a weight W acting over a pulley, which shall be sufficient to counterpoise the weight of the piston and its friction in the cylinder; and let the weight W be so arranged that from time to time its amount may be diminished to any required extent. Under the circumstances here supposed, the piston being in contact with the water, and all air being excluded from beneath it, it will be pressed down by the weight of the atmosphere, which we shall assume to be 14¾ lbs. Let it be also supposed that a thermometer is placed in the water under the piston, and that the tube A B is transparent, so that the indications of the thermometer may be observed. The temperature of the water under the piston being reduced to that of melting ice, which is 32° of the common thermometer, let the flame of a lamp be applied under the tube, and let the time of its application be noted. If the thermometer be now observed, it will be seen slowly and gradually to indicate an increasing temperature of the water, the piston maintaining its position in contact with the water unchanged. This augmentation of temperature will continue until the thermometer indicates the temperature of 212°. Let the time be then noted. It will be found that after that epoch, the water will cease to increase in temperature, notwithstanding the continued application of the lamp, the thermometer not rising above 212°. But another effect will begin to be manifested; the piston P will be observed gradually to rise, leaving a space apparently vacant between it and the water. The depth of the water will, however, be at the same time gradually diminished, and the diminution of its depth will be found to bear constantly the same proportion to the ascent of the piston. This proportion will render the circumstances here supposed to be that of 1700 to 1. If the application of the lamp be continued, and the tube have sufficient length, the water will, after the lapse of a certain time, altogether disappear from the bottom of the tube; and when that occurs, the piston will have risen to the height of 1700 inches, being 1700 times the original depth of the water.



The tube will now, to all appearance, be empty; but if the apparatus were weighed, it would be found to have the same weight as at the commencement of the experiment. The water, therefore, must still be contained in the tube, though it has assumed an invisible form. To demonstrate its presence, let the lamp be removed; immediately the piston will begin to descend, and the inner surface of the tube will be covered with a dew, which speedily increasing, will fall to the bottom in drops of water. The piston meanwhile will continue to move downwards, sweeping before it the water from the sides of the tube; and at length will recover its first position, having under it, as at the beginning, a cubic inch of water.

In the above process, the elevation of the piston is produced by the elastic force of the steam, into which the water was gradually converted by the lamp. The space between the piston and the water during its ascent, though apparently empty, was filled with steam; which, like air and most other gases, is a colourless and invisible fluid. The proportion of the elevation of the piston to the diminution of depth of the water being 1700 to 1, proves that the water in passing into steam increases its volume in that proportion. When the water altogether disappeared, the height of the piston from the bottom of the tube was 1700 inches; and as the tube under the piston was then filled with the steam into which the water had been converted, it is apparent that the cubic inch of water, in this case, was converted into 1700 inches of steam.

The pressure of the atmosphere above the piston was, in this case, overcome by the elastic force of the steam, and the piston, bearing that pressure upon it, was raised to a height of 1700 inches. In the evaporation, therefore,

of this cubic inch of water, a mechanical force has been evolved equivalent to $14\frac{3}{4}$ lbs. raised to the height of 1700 inches.

From the moment at which the water began to be converted into steam the thermometer, having then attained 212°, ceased to rise. Nevertheless, the application of the lamp was continued, and therefore the same quantity of heat per minute was still supplied to the water. Since the water did not increase in temperature, it may be asked what became of this continued supply of heat received from the lamp? It may be said that it was imparted to the steam into which the water was converted; but if the thermometer were raised out of the water, and held in the steam between the water and the piston, it would still indicate the same temperature of 212°. We thus arrive at the extraordinary and unexpected fact, that notwithstanding a large supply of heat imparted to water during its evaporation, that heat is sensible neither in the water itself nor in the vapour into which the water is converted.

The quantity of heat which is thus absorbed in converting water into steam is easily determined, the interval of time being noted which elapsed between the first application of the lamp and the moment at which the thermometer ceased to rise. Let us suppose that interval to be an hour; the interval being also noted between the moment the thermometer ceases to rise and the process of evaporation begins, and the moment at which the last particle of water disappears from the bottom of the tube and the evaporation is completed, it will be found that this interval is $5\frac{1}{2}$ hours; and in general, whatever may be the length of time necessary to raise the temperature of the water from 32° to 212°, $5\frac{1}{2}$ times that interval will be necessary for the same source of heat to evaporate the same quantity of water. It follows, therefore, that *to evaporate water under a pressure of* $14\frac{3}{4}$ *pounds per square inch requires* $5\frac{1}{2}$ *times as much heat as is necessary and sufficient to raise the same water from* 32° to 212°.

Since the difference between 212° and 32° is 180°, and since $5\frac{1}{2}$ times 180° is 990°, it follows that to convert the water into steam after it has attained the temperature of 212°, as much heat must be supplied to it as would be sufficient, if it were not evaporated, to raise it 990° higher. The heat thus absorbed in evaporation, and not sensible to the thermometer, is said to be latent in the steam; and the phenomena which have been just described form the foundation of the whole theory of *latent heat.* That this large quantity of heat is actually contained in the steam, though not sensible to the thermometer, admits of easy demonstration, by showing that it may be reproduced by converting the steam into water. If a cubic inch of water, in the form of steam at the temperature of 212°, be introduced into the same vessel with $5\frac{1}{2}$ cubic inches of water at the temperature of 32°, the steam will be immediately converted into water; the temperature of the $5\frac{1}{2}$ inches of ice-cold water will be raised to 212°, and there will be found in the vessel $6\frac{1}{2}$ cubic inches of water at 212°. Thus, while the steam, in reassuming the liquid form, has lost none of its temperature, it has nevertheless given up as much heat as has raised $5\frac{1}{2}$ cubic inches of water from 32° to 212°. It is therefore demonstrated that this quantity of heat was actually in the steam; and that it was its presence there in the latent state, by some agency not yet explained, that conferred upon the water in the vaporous form the property of elasticity.

We have here supposed that the pressure under which the water in the tube was evaporated was the mean pressure of the atmosphere, or $14\frac{3}{4}$ lbs. per square inch. Let us now suppose that the piston resting on the water is loaded with a force of $14\frac{3}{4}$ lbs., besides the pressure of the atmosphere, which may be done by taking $14\frac{3}{4}$ lbs. from the counterpoise W. If the same process be followed as before, it will now be found that the thermometer will not cease to rise when it has attained 212°; nor will the piston then begin to ascend. The thermometer will, on the other hand, continue to rise until it has attained 250°. It will then, as in the former case, cease to rise; the piston will ascend, and the water will begin to be converted into steam; the proportion, however, between the ascent of the piston and the diminished depth of the water, or, in other words, between the volume of steam produced and the volume of water producing it, instead of being 1700 to 1, will now be about 930 to 1, being little more than half the former proportion. The force against which the elasticity of the steam, in the present case, acts, is $29\frac{1}{2}$ lbs.; and this force is raised about 930 inches by the evaporation of a cubic inch of water. In the former case, a force of $14\frac{3}{4}$ lbs., being half the present force, was raised to 1700 inches by the evaporation of the same quantity of water. If the double force, instead of being raised 930 inches, had been raised only 850 inches, or half the first elevation, then the mechanical effect evolved would in both cases be precisely the same, the double resistance being raised through only half the space; but the actual height through which the double resistance is raised being 930 inches instead of 850, a greater mechanical effect is produced in the one case than in the other, in the proportion of 930 to 850, being an advantage on the part of the steam of greater pressure of about 8 per cent.

If the pressure under which the evaporation is produced were further varied, it would be found that with every increase of pressure the temperature at which the evaporation would commence would be augmented, and that with every diminution of pressure that temperature would be diminished. It would be also found that the volume of steam produced by a cubic inch of water would be less with every increase of pressure under which the evaporation is made; and that the diminution of volume would be nearly, but not in quite so great a proportion, as the increase of pressure. In like manner, if the pressure be diminished, the volume of steam produced by a cubic inch of water will be augmented in nearly, but not quite so great a proportion, as that of the diminution of pressure. From all this, it obviously follows that the mechanical effect evolved by the evaporation of a given volume of water under different pressures is very nearly the same; greater pressures, however, having a slight advantage over lesser ones.

It has been seen that $14\frac{3}{4}$ lbs. are raised to a height of 1700 inches by the evaporation of a cubic inch of water under the pressure of $14\frac{3}{4}$ lbs. per square inch. Now, 1700 inches are nearly equal to 142 feet; and $14\frac{3}{4}$ lbs. raised 142 feet is equivalent to 142 times $14\frac{3}{4}$ lbs. raised one foot, which is equal to very nearly 2100 lbs. raised one foot. To use round numbers, it may then be stated, that by the evaporation of a cubic foot of water a mechanical force is produced equivalent to a ton weight raised a foot high; and that this force is very nearly the same, whatever be the temperature or pressure under which the evaporation takes place.

In the following table, calculated by Dr. Lardner, and given by him in the Appendix to the 7th edition of his work on the *Steam Engine*, is exhibited the temperatures at which water is evaporated under different pressures, the volume into which the water expands by evaporation, the mechanical effect evolved expressed in lbs. raised one foot.

Total Pressure in Pounds per Square Inch.	Corresponding Temperature.	Volume of the Steam compared to the Volume of the Water that has produced it.	Mechanical Effect of a Cubic Inch of Water evaporated, in Pounds raised One Foot.

From what has been above explained, it is apparent that the quantity of sensible heat in steam is augmented with every increase of pressure under which the evaporation takes place; but if the interval of time be observed which elapses between the first application of the lamp to the ice-cold water in the experiment above described, and the moment at which the last particle of water disappears by evaporation from the bottom of the tube, it will be found that this interval is exactly the same, whatever be the temperature or pressure under which the evaporation takes place. It follows, therefore, that the actual quantity of heat necessary to convert ice-cold water into steam is the same, whatever be the pressure of the steam; but as the temperature of steam increases and diminishes as the pressure is increased or diminished, it follows that this given quantity of heat is differently distributed between sensible and latent heat in steam of different pressures. As the pressure is increased the sensible heat is augmented, and the latent heat undergoes a corresponding diminution, and *vice versâ*. The sum of the sensible and latent heats is, in fact, a constant quantity; the one being always increased at the expense of the other. It has been shown that in converting water at 32° of temperature, and under a pressure of $14\frac{3}{4}$ lbs. per square inch, it was necessary first to give it 180° additional sensible heat, and afterwards 990° of latent heat, the total heat imparted to it being 1170°. Such, then, is the actual quantity of heat which must be imparted to ice-cold water to convert it into steam. The actual temperature to which water would be raised by the heat necessary to evaporate it, if its evaporation could be prevented by confining it in a close vessel, will be found by adding 32° to 1170°. It may, therefore, be stated that the heat necessary for the evaporation of ice-cold water is as much as would raise it to the temperature of 1202°, if its evaporation were prevented. If the temperature of red-hot iron be, as is supposed, about 800°, and that all bodies become incandescent at the same temperature, it follows that to evaporate water it is necessary to impart to it 400° more heat than would be sufficient to render it red hot if its evaporation were prevented. As the mechanical effect evolved by water evaporated at all pressures is nearly the same, and as the quantity of heat necessary to effect that evaporation is also the same, it follows that the same quantity of fuel employed in the evaporation of water is productive of very nearly the same mechanical effect, whatever be the pressure of the steam.

Since the heat imparted to water in evaporation is necessary to sustain it in the form of vapour, it follows that if any portion of that heat be taken from it, the steam will not be lowered in temperature, but a portion of it will be reconverted into water; a process which is called *condensation*. To illustrate this, let us suppose the tube A B to be filled with steam of 212° of temperature, produced from a cubic inch of water evaporated under the pressure of $14\frac{3}{4}$ lbs. on the piston. If, by the application of external cold, or any other means, a quantity of heat be extracted from this steam, say as much as would be sufficient to evaporate the tenth of a cubic inch of water, then a tenth part of the steam in the tube will be condensed and deposited in the liquid state in the bottom, the piston will descend through a tenth of its entire height, and the steam remaining uncondensed will still have the temperature of 212° and the pressure of $14\frac{3}{4}$ lbs. per square inch, while the water in the bottom of the tube produced by the condensation will also have a temperature of 212°. The heat, therefore, which has been thus abstracted is the heat which was latent in the steam formed by the water thus deposited. And in the same manner, any heat which is drawn from the steam will be latent heat; a corresponding condensation will take place until all the steam has been condensed, and the piston brought into contact with the bottom of the tube. After that, any abstraction of heat must be made at the expense of the sensible heat of the water.

It has, in some works, been stated that by mere mechanical compression steam will be converted into water. This is, however, an error, since steam, in whatever state it may exist, must possess at least 212° of heat; and as this quantity of heat is sufficient to maintain it in the vaporous form, under whatever pressure it may be placed, it is clear that no compression or increase of pressure can diminish the actual quantity of heat contained in the steam; and it cannot, therefore, convert any portion of the steam into water.

If steam, by mechanical pressure, be forced into a diminished volume, it will undergo an augmentation both of temperature and pressure, the increase of pressure being greater than the diminution of volume; in fact, any change of volume which it undergoes will be attended with the change of temperature and pressure indicated in the above table. The steam, after its volume has been changed, will assume exactly the pressure and temperature which it would have in the same volume if it were immediately evolved from water. Thus, let us suppose a cubic inch of water converted into steam under a pressure of $14\frac{3}{4}$ lbs. per square inch, and at the temperature of 212°. Let its volume be then reduced by compression in the proportion of 1700 to 930. When so reduced, its temperature will be found to have risen from 212° to 250°, and its pressure will be increased from $14\frac{3}{4}$ lbs. per square inch to $29\frac{1}{2}$ lbs. per square inch; but this is exactly the state, as to pressure, temperature, and density, as the steam would be in if it were immediately raised from water under the pressure of $29\frac{1}{2}$ lbs. per square inch. It appears, therefore, that in whatever manner, after evaporation, the density of steam be changed, whether by expansion or contraction, it will still remain the same as if it were immediately raised from water in its actual state.

The circumstance which has given rise to the erroneous notion that mere mechanical compression will produce a condensation of steam is, that the vessel in which steam is contained must necessarily have the same temperature as the steam itself. If then the steam contained in the vessel be suddenly compressed, it will undergo as sudden an elevation of temperature; and the vessel containing it not receiving at the same time, from any external source, a corresponding increase of temperature, it will rob the steam of a portion of its heat, and a partial condensation will be produced, and will be continued until the temperatures of the steam and the vessel containing it shall be equalized.

Since water, in passing into steam, suffers a great enlargement of volume, steam, on the other hand, in being converted into water undergoes a corresponding diminution of volume. It has been seen that a cubic inch of water, evaporated at the temperature of 212°, swells into 1700 cubic inches of steam. It follows, therefore, that if a close vessel, containing 1700 cubic inches of such steam, be exposed to cold sufficient to take from the steam all its latent heat, the steam will be reconverted into water, will shrink into its original dimensions, and will leave the remainder of the vessel a vacuum. This property of steam has supplied the means, in practical mechanics, of obtaining that amount of mechanical power which the properties of the atmosphere confer upon a vacuum. If by any means whatever the space in a cylinder under the piston be rendered a vacuum, the atmospheric pressure will take effect above the piston, and will urge the piston downwards with a force amounting to about 15 lbs. on each square inch of the surface of the piston. To render

steam available for this purpose, it is only necessary to inject it into the cylinder until it expels from the cylinder all the atmospheric air or other uncondensable gases which the cylinder contains; and when that is effected, the pure steam which remains in the cylinder being suddenly condensed by the application of cold, leaves the cylinder a vacuum, and gives effect to the atmospheric pressure above the piston, as before explained. This is, in fact, the principle of the atmospheric engine.

The temperature and pressure of steam produced by immediate evaporation, when it has received no heat, save that which it takes from the water, have a fixed relation one to the other. If this relation were known, and expressed by a mathematical formula, the temperature might always be inferred from the pressure, or *vice versâ*. But physical science has not yet supplied any principles by which such a formula can be deduced from any known properties of liquids. In the absence, therefore, of any general relation established by direct reasoning, empyrical formulæ have been proposed which express, with more or less precision, this relation in different parts of the thermometric scale.

When the pressure under which the evaporation takes place does not exceed one atmosphere, or 15 lbs. per square inch, the relation between the temperature and the pressure will be expressed with sufficient accuracy by the following formulæ, proposed by Southern:—

$$P = 0{\cdot}04948 + \left(\frac{51{\cdot}3 + T}{155{\cdot}7256}\right)^{5{\cdot}13}$$

$$T = 155{\cdot}7256 \times \sqrt[5{\cdot}13]{P - 0{\cdot}04948} - 51{\cdot}3\,;$$

where P expresses the pressure in pounds per square inch, and T the temperature by Fahrenheit's thermometer.

For pressures exceeding one atmosphere and not exceeding four, the relation is expressed by the following formulæ, proposed by Tredgold:—

$$P = \left(\frac{103 + T}{201{\cdot}18}\right)^6$$

$$T = 201{\cdot}18\sqrt[6]{P} - 103\,;$$

or by the following formulæ,

$$P = \left(\frac{98{\cdot}806 + T}{198{\cdot}562}\right)^6$$

$$T = 198{\cdot}562\sqrt[6]{P} - 98{\cdot}806.$$

For pressures extending from four to fifty atmospheres, the following formulæ have been proposed by Messrs. Dulong and Arago:—

$$P = (0{\cdot}26793 + 0{\cdot}0067585\ T)^5$$

$$T = 147{\cdot}961\sqrt[5]{P} - 39{\cdot}644.$$

Biot has proposed a more general fomula, which expresses the relation between the pressure and the temperature, whatever be the pressure under which the evaporation takes place. Let p be the pressure, expressed in millimètres, of mercury at the temperature of melting ice; let t be the temperature of the water, taken on the centesimal air thermometer; and let a, a_1, a_2, b_1, b_2 be constant quantities, whose values shall be determined by the following conditions:—

$$\begin{aligned} a &= 5{\cdot}96131330259 \\ \log. a_1 &= \bar{1}{\cdot}82340688193 \\ \log. b_1 &= -\,0{\cdot}01309734295 \\ \log. a_2 &= 0{\cdot}74110951837 \\ \log. b_2 &= -\,0{\cdot}00212510583. \end{aligned}$$

The relation between p and t will then be expressed by the following formula,

$$\log. p = a - a_1\, b_1^{20 + t} - a_2\, b_2^{20 + t}.$$

M. Biot compared the temperatures and corresponding pressures, calculated by this formula, with the series determined by an extensive course of experiments undertaken by MM. Arago and Dulong by order of the French government, to those of the experiments of Taylor at lower temperatures, and to a numerous series of MSS. observations of M. Gay-Lussac, extending from the boiling point to temperatures considerably below that of melting ice, and found that the calculated and observed results corresponded within the limits of error of the experiments themselves. The formula first given above offer, however, much greater facility for practical calculation, and afford as accurate results as are required for all ordinary purposes.

The same difficulty which attends the establishment of a general formula expressing the relation between the temperatures and pressures of steam, also attends the determination of one expressing the relation between the pressure and the augmented volume into which the water expands by evaporation. Empirical formulæ have accordingly been likewise proposed to express this relation. The late Professor Navier proposed the following formula for this purpose.

Let V express the number of cubic inches of steam produced by one cubic inch of water, and let P express the pressure of this steam in kilograms per square metre; then we shall have

$$V = \frac{1000}{0{\cdot}09 + 0{\cdot}0000484\ P}.$$

This formula gives sufficiently accurate results when applied to pressures much above one atmosphere. It fails to give the same accuracy, however, when applied to lower pressures.

The following formulæ have been proposed by M. de Pambour:—

$$V = \frac{10{,}000}{0{\cdot}4227 + 0{\cdot}00258\ P},$$

which will apply to low pressures; and

$$V = \frac{10{,}000}{1{\cdot}421 + 0{\cdot}0023\ P},$$

which will be applicable to high pressures. In each of these P is expressed in pounds per square foot.

Dr. Lardner proposes the following modified formula, V and P retaining their signification:—

$$V = \frac{3875969}{164 + P},$$

which may be used in reference to low-pressure engines of every form, as well as for high-pressure engines which work expansively.

When the pressure is not less than 30 lbs. per square inch, the following formula will be more accurate:—

$$V = \frac{4347826}{618 + P}.$$

In the preceding observations steam has been considered as receiving no heat except that which it takes from the water during the process of evaporation, the amount of which, as has been shown, is 1170° more than the heat contained in ice-cold water. But steam, after having been formed from water by evaporation, may, like all other material substances, receive an accession of heat from any external source, and its temperature may thereby be elevated. If the steam to which such additional heat is imparted be so confined as to be incapable of enlarging its dimensions, the effect produced upon it by the increase of temperature will be an increase of pressure; but if, on the other hand, it be confined under a given pressure, with power to enlarge its volume, subject to the preservation of that pressure, as would be the case if it were contained in a cylinder under a moveable piston loaded with a given pressure, then the effect of the augmented temperature will be, not an increase of pressure, but an increase of volume; and the increase of volume in this latter case will be in exactly the same proportion as the increase of pressure in the former case.

These effects of elevated temperature are common not only to the vapours of all liquids, but also to all permanent gases; but, what is much more remarkable, the numerical amount of the augmentation of pressure or volume produced by a given increase of temperature is the same for all vapours and gases. If the pressure which any gas or vapour would have were it reduced to the temperature of melting ice be expressed by 100,000, then the pressure which it will receive for every degree of temperature by which it is raised will be expressed by $208\frac{1}{3}$; or, what amounts to the same, the additional pressure produced by each degree of temperature will be the 480th part of its pressure at the temperature of melting ice. From these data it is easy to obtain an algebraical expression by which the augmentation of pressure in a given volume, or, what is the same, the augmentation of volume under a given pressure for every increase of temperature, may be calculated.

Let v be the volume of any elastic fluid at the temperature of 32°; and let it be then supposed to be raised by the application of heat to the temperature T, if under a given pressure. Let its augmented volume be V. The increase of volume will then be $V - v$, while the increase of temperature will be $T^\circ - 32^\circ$. But since the increase of volume for *one* degree of temperature is $\frac{v}{480}$, the increase for $T^\circ - 32^\circ$ will be $\frac{v}{480} \times (T^\circ - 32^\circ)$; and therefore the augmented volume V will be

$$\begin{aligned} V &= v + \frac{v}{480}\,(T^\circ - 32^\circ). \\ &= v\left\{1 + \frac{T^\circ - 32^\circ}{480}\right\}. \end{aligned}$$

If V' be the volume at any other temperature T', we shall have

$$V' = v\left\{1 + \frac{T'^\circ - 32^\circ}{480}\right\}.$$

From whence we infer

$$\frac{V}{V'} = \frac{T + 448}{T' + 448};$$

by which, when the volume of steam at any one temperature is known, the volume at any other temperature may be found, supposing that the steam receives no accession of water by evaporation.

Steam which thus receives additional heat after its separation from the water from which it is evolved has been called by Dr. Lardner *superheated steam*, to distinguish it from *common steam*, which is that usually employed in steam engines. *Superheated steam* admits of losing a part of its heat without suffering partial condensation; but *common steam* is *always* partially condensed if any portion of heat be withdrawn from it. For further details on these properties, see *Lardner on the Steam Engine*, 7th ed. p. 168. *et seq.*; also Appendix. See also *Lardner on Heat*, chap. viii., *Cabinet Cyclopædia*.

In the mechanical operation of steam, which has been already explained, the pressure, density, and temperature of the steam are supposed to remain the same during its action, and the mechanical effect is produced by the continual increase of the quantity of steam produced by evaporation. Thus, the piston in the apparatus represented in the figure is moved upwards, not by any change in the temperature, density, or pressure, but by the increased volume required by the continual production of steam. It has been proved that by this process alone the evaporation of a cubic inch of water, whatever be the pressure under which it takes place, evolves a mechanical force equivalent to a ton weight raised a foot high. But if, after this evaporation has been completed, the steam be separated from the water which produced it, and the load on the piston be gradually diminished, the steam would expand by moving the piston upwards in virtue of its excess of pressure, and this expansion will continue until the pressure of the steam shall be reduced to equality with the load on the piston. All mechanical effect developed in this process is due to the steam itself, independently of any further evaporation.

To make this important quality of the expansive action of steam understood, let us suppose the piston loaded with a pressure amounting to four times that of the atmosphere, including that of the atmosphere itself. If the water under the piston be evaporated under this pressure, it will have a temperature of about 291°, and by its evaporation the piston will be raised 40 feet. This will, therefore, be the whole mechanical effect arising from the immediate evaporation of the water. But when the evaporation has been completed, and the piston, with its load of four atmospheres, stands suspended at 40 feet above the bottom of the tube, let a pressure equal to that of one atmosphere be removed from the piston. The remaining pressure of three atmospheres being less than that of the steam below the piston, the piston will be raised, and will continue to rise until it has attained a height of about 50 feet, and the temperature of the steam thus expanded will fall to about 275°; and its pressure being reduced to that of three atmospheres, it will cease to rise. By this process, therefore, a mechanical force has been obtained from the steam equal to the weight of three atmospheres raised 10 feet, in addition to the effect obtained by immediate evaporation; but the expansive action does not stop here. Let it be supposed that the piston is again relieved from the pressure of another atmosphere, the superior pressure of three atmospheres below will cause it to rise, and it will ascend to the height of about 75 feet, the temperature of the steam falling to about 250°, and its pressure being reduced to two atmospheres. A further mechanical effect equivalent to the weight of two atmospheres raised to about 25 feet, has thus been obtained; and it is evident that by constantly and gradually diminishing the load on the piston, an additional effect may be always obtained from a given amount of evaporation, to an extent which is only limited by practical circumstances which restrain the application of this expansive principle. Since the cost of producing steam as a mechanical agent depends chiefly on the quantity of fuel necessary to effect the evaporation of a given volume of water, it follows that all the mechanical effect obtained by this principle of expansion is so much power added to the steam without further expense. Its importance, therefore, will be obvious in the economy of steam power. For the manner of rendering it available in steam machinery, see STEAM ENGINE.

History of Steam. — The nature and properties of steam were altogether unknown to the ancients. Some accounts have come down to us bearing a very early date of engines; such, for example, as that proposed by Hero of Alexandria, in which the mechanical agency of steam was more or less used; but it does not appear that those who invented and applied these machines comprehended the properties of vapour, or had any correct notion of the phenomena produced by the application of heat to liquids. Even at a much more recent period the effects produced by steam were ascribed, not to the vapour of water, but to the force of air which was supposed to be expelled from water by heat. In the beginning of the 17th century, De Caus proposed the construction of a machine by which a column of water was raised by the elastic force of steam; but there is no sufficiently distinct explanation of the properties of vapour in his description of that machine to warrant the conclusion that he comprehended the elasticity of the vapour of water. About the middle of the same century, Lord Worcester published the description of a high-pressure steam engine, which has since formed so remarkable a feature in all histories of that machine. Towards the latter end of that century, however, the actual properties of vapour began to be gradually unfolded. In 1683, Sir Samuel Moreland published a description of the force of steam, in which he assigned very nearly the exact numerical proportion in which water increases its volume when evaporated under the pressure of a single atmosphere. A few years after this, Papin discovered the method of producing a vacuum by the condensation of steam; and in the course of the next half century the elastic force of steam, and the circumstances attending its condensation, became gradually better understood, having been applied to mechanical purposes by Savery, Newcomen, and others. About the middle of the 18th century, the celebrated Watt applied himself to the improvement of the steam engine, and by various experiments determined the relative volumes of steam as commonly used in steam engines, and the quantity of heat absorbed in evaporation and evolved in condensation. About the same period Dr. Black was engaged in his well-known investigations respecting the phenomena of heat, and had discovered the phenomena and found the theory of latent heat, which served to explain the effects which Watt had also observed. During the latter part of the 18th and the beginning of the present century, the physics of heat, and more especially those principles immediately connected with steam, were rapidly advanced. The relation between the temperatures and pressures of the vapour of water throughout the common range of the thermometric scale was determined by Dalton, and confirmed by Gay-Lussac, Prof. Robison, Ure, Southern, and others. The discovery of the law in virtue of which the pressure of all gases and vapours increases in proportion to their density at a given temperature was due to Mariotte, and is known as Mariotte's law. The discovery of the remarkable fact that all gases and vapours receive the same increase of pressure or volume for each degree of temperature was first discovered by Dalton; but was immediately afterwards discovered also by Gay-Lussac, who was not informed of Dalton's proceedings. The most important course of experiments which has since been made were undertaken by a committee of the French Institute, consisting of MM. Prony, Arago, Gerard, and Dulong, in consequence of an application from the French government to the academy to point out the best means of preventing accidents from the bursting of the boilers of steam engines. The experiments were conducted chiefly by Arago and Dulong, and were certainly not only the most delicate as to their management, but the most hazardous which science and art owe to the courage and zeal of philosophers. Steam was produced of a sufficient pressure to force a column of mercury up a glass tube to the height of nearly 43 feet; an atmosphere being measured by a column of mercury measuring 29·922 inches. The following table exhibits the temperatures and corresponding pressures of steam, as determined by these experiments, up to fifty atmospheres.

Pressure in Atmospheres.	Temperature.	Pressure in Atmospheres.	Temperature
1	212°	13	380·66°
1½	234	14	386·94
2	250·5	15	392·86
2½	263·8	16	398·48
3	275·2	17	403·83
3½	285	18	408·92
4	293·7	19	413·78
4½	300·3	20	418·46
5	307·5	21	422·96
5½	314·24	22	427·28
6	320·36	23	431·42
6½	326·26	24	435·56
7	331·7	25	439·34
7½	336·86	30	457·16
8	341·78	35	472·73
9	350·78	40	486·59
10	358·88	45	499·14
11	366·85	50	510·6
12	374		

The last six temperatures in the above table are deduced by calculation from the formula $e = (1 + 0·7153t)^5$, in which e expresses the elasticity in atmospheres, and t the temperatures in centième degrees, beginning from 100°, and proceeding upwards. The methods employed in this magnificent course of experiments will be found detailed in the *Annales de Chimie et de Physique*, tome xliii. p. 74.

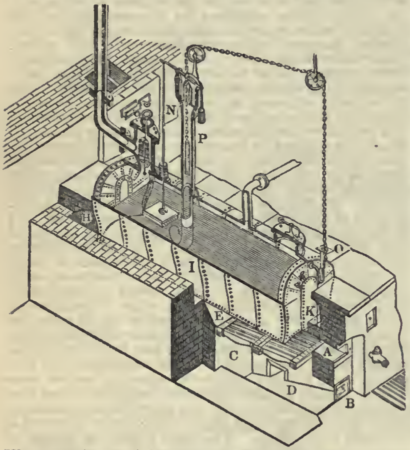
The committee seized the opportunity presented by

the apparatus used for these experiments for testing Marriotte's law, as applied to atmospheric air; and they found that it agrees with experiment as far as a pressure of twenty-four atmospheres.

For further details respecting the properties of steam, see *Dr. Lardner on the Steam Engine*, 7th edition; *Lardner on Heat, Cabinet Cyclopædia; De Pambour on the Steam Engine;* various articles on Steam and Vapour, in the Philosophical Transactions in the *Proceedings of the Institute of France;* the *Annales de Chimie et Physique;* the *Annales de Mines;* the *Journal des Ponts et Chaussées*, &c. &c.

STEAM BOILER. A vessel in which water is converted into steam for the purpose of supplying steam engines, or for any other purposes for which steam is used in the arts, or in domestic economy.

The most common form of boiler used for steam engines is that called the *waggon boiler*, an isometric view of which is given in the cut. The form of boiler adopted by



Watt consisted of a semi-cylindrical top, flat perpendicular sides, flat ends, and a slightly cancave bottom. That which is represented in the cut has sides a little concave. The steam used in these boilers does not exceed the pressure of the atmosphere by more than 5 lbs. per square inch; and the sides and ends, though not so favourable to strength as the cylindrical form, are sufficiently strong for this pressure. In a boiler of this form the air and smoke, passing through flues that are carried round it, are in contact at one side only with the boiler. The brickwork or other materials forming the flue must therefore be non-conductors of heat, that they may not absorb any considerable quantity of heat from the air passing in contact with them.

The grate and a part of the flues are rendered visible in the figure, by the removal of a portion of the surrounding masonry in which the boiler is set. The interior of the boiler is also shown by cutting off one half of the semi-cylindrical roof. The door by which fuel is introduced upon the grate is represented at A, and the door leading to the ash-pit at B. The fire-bars at C slope downwards from the front at an angle of about 25°, giving a tendency to the fuel to move towards the back of the grate. The ash-pit D is constructed of such a magnitude, form, and depth, as to admit a current of atmospheric air to the grate-bars sufficient to sustain the combustion.

The fuel, when introduced at the fire-door, is laid on that part of the grate next the fire-door which is called the *dead plates.* There it is submitted to the process of coking, by which the gases and volatile matter are expelled from it; and being carried by a current of air admitted through small apertures in the fire-door over the burning fuel in the hinder part of the grate, they are burnt. When the fuel in the front of the grate has been thus *coked* it is pushed back, and a fresh feed is introduced upon the dead plates. The coal thus pushed back soon becomes vividly ignited, and by continuing this process, the fuel spread over the grate is maintained in the most active state of combustion in the hinder part of the grate. By such an arrangement the smoke produced by the combustion will be burnt before it enters the flues. The flame and heated air proceeding from the fuel rushing to the back of the furnace pass over the fire-bridge E, and being carried through the flue, pass below the concave base of the boiler. This bottom flue is very nearly equal in width to the base of the boiler, the space left near the corners being only what is sufficient to support the weight of the boiler resting on the masonry. The bottom of the boiler being concave, the flame and heated air rise to the upper part of the flue by the effect of their high temperature, and *lick* the bottom from the fire-bridge to the further end.

The flue rises at the back of the boiler, and returns along the side from H to I. It then passes in front of the boiler at K to the opposite side, along which it is again carried from the front to the back of the boiler. At the back it finally turns upwards to the base of the chimney.

By this arrangement the flame and heated air are made to circulate round the boiler; and the length and magnitude of the flues should be such that when it arrives at the chimney its temperature shall be reduced, as nearly as is consistent with the maintenance of the draught, to the temperature of the water with which it is in contact.

The magnitude of the grate and ash-pit must be determined by the rate at which the evaporation is to be produced in the boiler. There is no well-established rule for this. Some engine-makers allow a square foot of grate surface for each cubic foot of water to be evaporated per hour, while others only allow half this for the same evaporation and the same quantity of fuel. Practice varies between these limits.

To facilitate the raking out of the grate, the bars are placed with their ends towards the fire-door. They are made of cast iron about two inches broad on the upper surface, and with intervals of half an inch between them.

They taper downwards, the spaces between them widening, to facilitate the fall of the ashes between them. The height of the centre of the bottom of the boiler above the front of the grate is usually about two feet, and about three feet above the back of it.

Between the evaporating power of the boiler and the magnitude of surface it exposes to the action of the fire, there is a relation not yet satisfactorily ascertained. That part of the surface immediately over the grate is probably the most efficient in producing steam. The tendency of the flame to rise would naturally bring it more in contact with those parts of the boiler which are horizontal in their position, and which form the tops of the flues, than with those which are vertical or lateral. In the boiler here represented the most efficient surface would therefore be the bottom of the boiler. Engine-builders vary much in the quantity of surface which they allow for a given rate of evaporation. Some allow twelve and some eighteen square feet of surface for each cubic foot of water per hour to be evaporated.

The capacity of the boiler is appropriated to a two-fold purpose: 1. to contain the water to be evaporated; 2. to contain a quantity of ready-made steam to supply the engine. The proportion of the steam space in the boiler to the volume of the cylinder has been variously estimated. It is held by some that it will be sufficient if it be five times the volume of the cylinder, while others allow double that quantity.

For every cubic foot of water per hour intended to be evaporated, water space should be allowed in the boiler for at least five cubic feet; so that one fifth of the contents are evaporated per hour.

The surface of the water in the boiler must be matter of careful and exact regulation. It should *always* be *above* the range of the flues. When the heat in the flues acts upon a part of the boiler which is not in contact with water, steam being a slow recipient of heat, the heat accumulates in the boiler plates, and raises their temperature to an injurious degree. The plates may be by this means softened, so as to cause the boiler to burst; or the difference between the expansion of these highly heated plates and of those in contact with water may cause the joinings of the plates to open and the boiler to leak. By whatever means, therefore, the boiler be fed, the level of the water ought never to be allowed to fall below the highest flue.

Since the level of the water in the boiler ought to be maintained in a steady position, it is evident that the magnitude of the feed must be equal to the quantity of water evaporated. If, therefore, one fifth of the water in the boiler be evaporated per hour, that quantity ought to be introduced by the feeding apparatus in the same time. To regulate the feed with safety and certainty, it is necessary to provide an indicator of the level of the water in the boiler.

This is accomplished by a float which rests on the surface of the water suspended by a wire, which passes steam-tight through a small hole in the top of the boiler, and is connected by a flexible chain or string, passing over a wheel with a counterpoise, which is only capable of balancing the weight of the float when the latter is sustained by its buoyancy in the water. The position of the counterpoise will depend on that of the float; when the latter falls the counterpoise must rise, and *vice versâ*. The position of the counterpoise, therefore, will always indicate that of the float, and of the surface of the water on which the float rests.

There are other methods of indicating the quantity of water to the *eye* and the *ear* (see *Lardner on the Steam Engine*, p. 266. *et seq.*); but that which is most deserving of notice is one in which the indicator is made to govern the feeder, so as to supply water to the boiler in the same proportion as that in which it is evaporated. The wire supporting the float on the surface of the water above described, represented at N in the figure, is attached to the arm of a lever, of which the opposite arm is connected with a common puppet valve placed in the bottom of the small feeding cistern. When the surface of the water falls, the float falls with it, and draws down the arm of the lever, which raises the opposite arm and opens the valve. Water from the feeding cistern flows into the boiler through the tube P, and continues to flow into it until the level of the surface has been raised so high that the float no longer pulls down the arm of the lever, and therefore the valve in the bottom of the cistern is closed. In the actual operation of this self-acting feeder, however, the surface of the water so adjusts itself that the float opens the valve just so much as is necessary, and sufficient to admit as much water from minute to minute as is consumed by evaporation, and therefore the level of the water is maintained in a fixed position.

To secure the safety of boilers it is necessary to provide means for preventing the pressure of the steam contained in them from exceeding a certain limit, and also for indicating its pressure at all times. The former object is attained by safety valves, which are of various forms. The safety valve is a common puppet valve placed on the top of the boiler, which opens upwards, and which is held down by a pressure proportional to the limit within which the steam is intended to be kept. When the pressure of the steam exceeds that limit, this valve is raised by it, and the steam escapes until its pressure is reduced to below that of the valve. The magnitude of the aperture of the valve should be sufficient to enable the steam to escape faster than under any possible circumstances it could be generated. Safety valves differ one from another, chiefly in the manner in which the required pressure upon them is produced. In some weights of the requisite amount are placed directly upon the valve, as represented in the figure under N. In some the valve is held down by the elasticity of one or more springs. In others a lever presses on the valve by a sliding weight, the pressure being varied at discretion by shifting the position of the weight; and in others the lever which acts on the valve is held down by a spring similar to that of the common spring balances, which may be screwed up to any required tension. In *all* boilers true safety valves should be provided, one of which should be placed out of the reach of the engineer, so as to impose a major limit to the pressure which he can give to the steam.

The most ordinary indicator of the pressure of the steam in low-pressure boilers is the *mercurial steam gauge*, represented at O in the figure, which consists of a glass tube bent into the siphon form, the bent part and a portion of each leg being filled with mercury. One leg communicates with the steam within the boiler, and the other is open to the atmosphere. The difference between the levels of the columns of mercury in the two legs is always a measure of the difference between the pressure of the steam and that of the atmosphere. If the tube be of iron, which is most generally the case, the position of the surface of the mercury in it is indicated by a float having a wooden rod rising from it.

This indicator cannot be conveniently applied to high-pressure boilers, since the column of mercury supported by the pressure of the steam would have too great a height. In these boilers a thermometer is immersed, by which the temperature of the steam is indicated; and this becomes an indicator to its pressure, since the pressure varies with the temperature. *See* STEAM.

The safety of high-pressure boilers is sometimes provided for, by inserting in them a plug of metal capable of being fused at that temperature above which the boiler is exposed to the danger of explosion. If the water and steam exceed that temperature, the metal of the plug or of its solder will melt, and it will fall out, and the steam will escape from the opening which it leaves. An alloy composed of one part of lead, three of tin, and five of bismuth, will fuse at the common temperature of boiling water; and alloys of the same metals in various proportions will fuse at different temperatures from 200° to 400°.

When a boiler ceases to be worked and the furnace is extinguished, the space within it appropriated to steam will be left a vacuum by the condensation of the steam with which it was previously filled. The external pressure of the atmosphere acting on the boiler would, under such circumstances, have a tendency to crush it inwards. To prevent this a safety valve is provided, opening inwards, and balanced by a weight to keep it closed until it be relieved from the pressure of the steam within.

To render the strength of the fire proportional to the evaporating power, a plate called a *damper* is placed with its plane at right angles to the flue, so that by raising and lowering it like the sash of a window the space for the passage of air through the flue is increased or diminished. The force of draft and that of the fire can, therefore, be varied merely by shifting the position of the damper.

Such a damper can be regulated by hand, but more uniformly by connecting it with a float placed on a column of water or mercury, which measures the force of the steam, as represented in the figure, where the chain suspending the damper is seen at O and the float at P. If the force of the steam be suddenly increased, such a column will raise the float and lower the damper; and if the force of the steam be too feeble, the contrary effect will be produced. Such an apparatus is called *a self-regulating damper*.

The form of boilers is sometimes cylindrical, having an oval flue conducted through them from end to end. The ends are hemispherical. Such a form is favourable to strength, and is better adapted than the waggon shape to high-pressure boilers.

(For the boilers of railway engines, *see* LOCOMOTIVE ENGINE; and for those of marine engines, *see* STEAM NAVIGATION. For more minute details respecting steam boilers, see *Lardner on the Steam Engine*, 7th edition; also *Tredgold*, second edition, Appendix.)

STEAM CARRIAGE. A name usually applied to locomotive engines adapted to work on common roads.

The principle of the construction of these is, in its general conditions, similar to that of the locomotive engine used on railways (*see* LOCOMOTIVE ENGINE); but the engine adapted to common roads must have the same power, with a much less weight; or, in other words, the ratio of the weight of the engine to the evaporating power of the boiler is much less than in the case of railway locomotives.

Although the attempt made to adapt the steam engine as an accessory power on common roads has not hitherto been productive of any practical result of a permanent nature, this has not arisen so much from the failure of steam power to accomplish the traction of carriages, as from the greater expense of that power, as compared either with horse power on common roads or with steam power on railways. At the time when the construction of railways throughout the country was extensively undertaken, and when the great power and economy of the locomotive engine upon them was demonstrated by the results of the traffic on the Liverpool and Manchester railway, several projects for the application of the locomotive engine on common roads were in progress, and were attended with effects which presented a fair prospect of ultimate success. The establishment of the great lines of railway communication throughout the kingdom, by engrossing the traffic of all those districts in which the locomotive engine on common roads promised greatest advantage, and on which, if any where, it would have taken the place of horse power, discouraged speculators, and most of the projects which had been in progress fell to the ground. Among these were the steam carriages of Mr. Gurney, Col. Maceroni, Mr. Hancock, Dr. Church, Mr. Ogle, Mr. Russell, and various others.

The engine in steam carriages generally acts either directly on the wheels, and causes them to revolve, and thereby propels the carriage; or it acts on cranks formed on the axle of the wheels, and the wheels being keyed upon the axle are compelled to revolve with it. In either case, the revolution, whether of the wheels or the axle, is produced by a connecting rod jointed on the end of the piston rod, and receiving motion from the piston rod. The wheels are generally driven by two pistons working in two cylinders, so that one is at its dead point when the other is in the position most favourable for its action. The arrangement of this part of the machinery being similar to that of the railway locomotive, need not be here more fully described.

The steam carriages of different projectors differ one from another, chiefly in the boilers, and in the apparatus for generating the steam and admitting it to the cylinder. Mr. Gurney's boiler consisted of a series of strong iron tubes placed side by side, so as to form the bars of the grate of the furnace. These were connected with another system nearly at right angles to them, forming the back of the furnace; and these again with a third system, forming the roof of the furnace. The tubes forming the grate bars had their ends inserted in a strong iron cylinder, having it axis horizontal, and its length extended across the front of the furnace under the fire-door; and the tubes forming the roof of the furnace were inserted in a similar cylindrical vessel, extending in like manner across the front of the furnace *above* the fire-door. These two cylinders were likewise connected by upright cylinders of less diameter placed at each side of the fire-door. This system of tubes and cylinders being filled with water, the heat of the furnace acting on the tubes surrounding the fireplace, and the heated air and flame being afterwards conducted above the tubes forming the roof of the fireplace, before it escaped into the chimney steam was produced in the tubes, which by its lightness passed from them to the cylindrical vessel extending over the fire-

door. From that vessel the steam passed into a larger cylindrical vessel above it, called a *separator*, its purpose being to disengage the pure steam from the spray of water with which it is generally mixed when it first escapes from the boiling water in a state of violent agitation.

Every part of this boiler being cylindrical, has the form which is most favourable to strength, and which, within given dimensions, contains the greatest quantity of water. The tubes surrounding the furnace can freely expand in the direction of their length, without being loosened at the joints, and without straining any part of the apparatus. Proper means of opening the tubes at their ends are provided, by which they may be scraped on the inside, and cleansed from any deposit which may be left in them by the water evaporated in them.

In these engines the draught of the furnace was produced by projecting the waste steam into the chimney; but instead of dismissing it directly from the eduction pipe of the cylinder to the chimney, it was conducted to a receptacle called a *blowing box*. This box served the same purpose as the upper chamber of a smith's bellows. It received the steam from the cylinder in alternate *puffs*, but it let it escape into the chimney in a continued stream by a number of small jets. A regular draught was by this means produced, and no noise was perceived.

The pipe through which the boiler is fed was carried through this blowing box in a spiral form, so that an extensive thread of the feeding water was exposed to the heat of the waste steam as it passed from the cylinders. In passing throught his box the feeding water was raised from 60° to 212°, at which temperature it was forced into the boiler.

A steam carriage constructed by Mr. Gurney, weighing 35 cwt., working for eight hours, was found, according to Mr. Gurney's statement, to do the work of about thirty horses. The engine was placed on a carriage separate from that which bore the passengers, and the one drew the other after it in the same manner as the railway engine draws its train. Mr. Gurney stated that the weight of an engine sufficient to draw after it a carriage containing eighteen passengers would be about a ton; so that the gross weight of the whole, the engine and carriage for passengers taken together, would not exceed that of a common stage coach and four horses.

In the steam carriage proposed by Mr. Hancock, and which was worked for some time on the New Road and other roads about London, the engine and passengers were placed in the same carriage. In the boiler the subdivision of the water, so as to expose a sufficient surface to the action of the fire, was accomplished by dividing a case or box by a number of thin plates of metal like a galvanic battery, the water being allowed to flow between every alternate pair of plates, the intermediate spaces forming the flue through which the flame and hot air pass. In fact, a number of thin plates of water are exposed on both sides to the most intense action of flame and heated air; so that steam of a high pressure is produced in great abundance, and with considerable rapidity. The plates forming the boiler were bolted together by strong iron ties, extending across the boiler at right angles to the plates. The distance between plate and plate was two inches.

There were ten flat chambers of this kind for water, and intermediately between them ten flues. Under these flues was the fire-grate, six square feet in magnitude. The water spaces were filled to about two thirds of their depth with water, and the other third was left for steam. The water chambers throughout the whole series communicated with each other at top and bottom, and were held together by two large bolts. By releasing these bolts at any time, the chambers fell asunder; and by screwing them up, they might be all made tight again.

These boilers were constructed to bear a pressure of 400 or 500 lbs. per square inch; but the safety valve was screwed up to a pressure not exceeding 100 lbs. per inch. There were 100 square feet of surface exposed to the fire. The stages which the engine performed were eight miles, after which a fresh supply of water and fuel was taken in.

Mr. Nathaniel Ogle of Southampton obtained a patent for a locomotive carriage, which he worked for some time experimentally. In his evidence before the House of Commons, he has there described his contrivance. "The base of the boiler and the summit are composed of cross pieces, cylindrical within and square without; there are holes bored through these cross pieces, and inserted through the whole is an air tube. The inner hole of the lower surface, and the under hole of the upper surface, are rather larger than the other ones; round the air tube is placed a small cylinder, the collar of which fits round the larger aperture on the inner surface of the lower frame and the uuder surface of the upper framework. These are both drawn together by screws from the top; these cross pieces are united by connecting pieces, the whole strongly bolted together; so that we obtain in 1-10th of the space, and with 1-10th of the weight, the same heating surface and power that are now obtained in other and low-pressure boilers with incalculably greater safety. Our present experimental boiler contains 250 superficial feet of heating surface, in the space of 3 feet 8 inches high, 3 feet long, and 2 feet 4 inches broad, and weighs about 8 cwt. We supply these two cylinders with steam communicating by their pistons with a crank axle, to the ends of which either one or both wheels are fixed, as may be required. One wheel is found to be sufficient, except under very difficult circumstances and when the elevation is about 1 foot in 6, to impel the wheel forward.

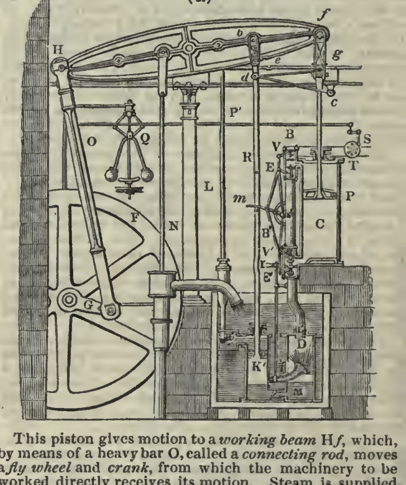
"The cylinders of which the boiler is composed are so small as to bear a greater pressure than could be produced by the quantity of fire beneath the boiler; and if any one of these cylinders be injured by violence, or any other way, it would become merely a safety valve to the rest. We have never, with the greatest pressure, burst, rent, or injured our boiler; and it has not once required cleaning, after having been in use twelve months."

For more full details respecting steam carriages, see *Lardner on the Steam Engine*, 7th edit.; also a Treatise on *Elemental Locomotion*, by Alexander Gordon, C.E.

STEAM-ENGINE. A machine in which the mechanical power developed in the evaporation of water is rendered available as a moving power. Steam engines vary much in magnitude, form, and proportions, as well as in the details of the machinery by which the power of the steam is adapted as a prime mover. We shall first explain those forms of steam-engine most generally used in the arts and manufactures, and shall afterwards give a succinct account of the history of the invention and progressive improvement of this machine. The forms of engine, and the mode of its application to transport by land and water, have been consigned to separate articles. *See* LOCOMOTIVE ENGINE, RAILWAYS, and STEAM NAVIGATION.

Double-acting Condensing Steam Engine.—This form of engine is that which is almost invariably used as a moving power in all manufactures in this country. It consists of a cylinder represented in section at C, in which a moveable piston P is driven upwards and downwards by the force of steam supplied by a boiler placed near the engine. *See* STEAM BOILER.

(1.)



This piston gives motion to a *working beam* H*f*, which, by means of a heavy bar O, called a *connecting rod*, moves a *fly wheel* and *crank*, from which the machinery to be worked directly receives its motion. Steam is supplied from the boiler to the cylinder by the steam pipe S. The *throttle-valve* T in that pipe, near the cylinder, is regulated by a system of levers connected with the *governor* Q. This governor is an apparatus consisting of two heavy balls attached to the ends of rods which are kept revolving on a vertical shaft by a cord or band, or by a train of cogged wheels connected with the fly-wheel. The velocity with which the balls of the governor revolve is therefore always proportional to that of the fly-wheel, and of the machinery driven by it. If by reason of too rapid a supply of steam an undue speed be imparted to the fly-wheel, the balls are whirled round with a corresponding velocity; and by reason of their centrifugal force they recede from the vertical spindle round which they turn, and acting thereby on the system of levers which connect them with the throttle-valve T, they partially close the latter, check or diminish the supply of steam to the cylinder, and moderate the velocity of the machine. If, on the other hand, the motion of the engine be slower than is requisite, owing to a deficient sup-

ply of steam through S, then the balls, not being sufficiently affected by centrifugal force, fall towards the vertical spindle, and acting on the system of levers in the contrary way, they turn the throttle-valve T more fully open, and admit a more ample supply of steam to the cylinder, so as to increase the speed of the engine to the requisite limit.

The piston P is accurately fitted to the cylinder, and made to move in it steam-tight by packing, with which it is surrounded. This piston divides the cylinder into two compartments, between which there is no communication by which steam or any other elastic fluid can pass. A case B B′ placed beside the cylinder contains the valves by means of which the steam which impels the piston is admitted and withdrawn as the piston commences its motion in each direction. The *upper steam-box* B is divided into three compartments by two valves ; above the upper steam-valve V is a compartment communicating with the steam-pipe S. Below the exhausting valve E is another compartment communicating with a pipe called the *eduction pipe*, which leads downwards from the cylinder to a vessel called the condenser, which we shall presently describe. By this eduction pipe the steam is withdrawn from the cylinder after it has driven the piston. By the valve V a communication may be opened or closed between the boiler and the top of the cylinder, so as to admit or intercept the supply of steam from the one to the other. By the valve E a communication may be opened or closed between the top of the cylinder and the condenser, so that the steam in the top of the cylinder, may either be permitted to escape into the condenser or confined in the cylinder. The continuation S′ of the steam-pipe leads to the *lower steam-box* B′, which like the upper is divided into three compartments by two valves V′ and E′. The upper compartment communicates with the steam-pipe S′, and the lower with the eduction-pipe. By means of the valve V′ steam may be admitted from the steam-pipe S′ to the bottom of the cylinder, and by means of the valve E′ this steam may be permitted to escape to the condenser.

The four valves V, E, V′, and E′ are in the engine represented in the figure connected by a system of levers with a single handle or *spanner*, *m*, which being pressed upwards or downwards opens and closes the valves in pairs. Thus when it is pressed *down* the levers connected with it raise the upper exhausting valve E and the lower steam valve V′, and close the upper steam valve V and the lower exhausting valve E′. On the other hand, when the spanner *m* is pressed *up* it opens the upper steam valve V and the lower exhausting valve E′, and at the same time closes the upper exhausting valve E and the lower steam valve V′.

The cylinder is closed at the top, and the piston-rod P, being accurately turned, runs in a steam-tight collar furnished with a shifting box, by means of which it is surrounded by a packing of hemp and constantly lubricated with melted tallow. A funnel is screwed on the top of the cylinder, through which, by opening a stop-cock, melted tallow is permitted to fall from time to time on the piston so as to lubricate it.

The condenser D is submerged in a cistern of cold water ; at its side there enters a tube I′ governed by a cock I, which being opened or closed to any required extent a jet of cold water may be allowed to play in the condenser. This jet throws the water upwards towards the lower orifice of the eduction pipe L′. From the bottom of the condenser D proceeds a tube having a valve M in it opening outwards ; this tube leads to the *air-pump* K′, which is a pump submerged in the same cistern with the condenser, worked by a piston having a valve in it opening upwards. The piston-rod R of the air-pump is carried upwards, and attached at *d* to a system of jointed rods called the *parallel motion*, to which is also attached at *g* the great steam-piston rod. On the rod of the air-pump is placed projecting pins, which as it alternately ascends and descends strike the spanner *m*, and thereby open and close the valves V, V′, E, E′, in pairs, as already described.

The upper part of the air-pump cylinder communicates by a valve opening outwards with a small cistern K, called the *hot well*, for a reason which will presently appear. A pump L, called the hot water pump, descends into the hot well and is worked by the great working beam to which its rod is attached.

If the machine thus arranged continued to be worked for any length of time, the cistern of water in which the condenser and air-pump are immersed would become warm, and the condenser would be rendered incapable of doing that for which alone it is useful, viz. of reducing the steam to water *by cold*. To prevent this a pump N is provided, called the *cold water pump*, by which a supply of cold water is constantly kept flowing into the cistern, the heated water being at the same time allowed to escape by a waste pipe. By this means the temperature of the water in the cold cistern is kept so low as to be capable of effectually condensing the steam.

The piston being supposed to be at the top of the cylinder, the spanner *m* will be raised by the lower pin on the air-pump rod, and the valves V and E′ will be opened, and at the same time the other pair of valves V′ and E will be closed. Steam will therefore be admitted above the piston, and the steam which had previously filled the cylinder below the piston will be drawn off to the condenser. It will there encounter the jet of cold water, which is kept constantly playing there by keeping the cock I sufficiently open. It will thus be immediately reduced to water or condensed (*see* STEAM), and the cylinder below the piston will remain a vacuum. The steam, therefore, admitted from the steam-pipe through the open valve V to the top of the cylinder, will press the piston to the bottom of the cylinder. As it approaches that position the spanner *m* will be struck downwards by the upper pin on the air-pump rod, and the valves V and E′ previously open will be closed, while the valves V′ and E previously closed will be opened. The steam which has just pressed down the piston, and which now fills the cylinder above the piston, will then flow off through the open valve E by the eduction-pipe to the condenser, where it will be immediately condensed by the jet of cold water which constantly plays there, and steam from the boiler admitted through the open valve V′ will fill the cylinder below the piston and press the piston upwards. When the piston has reached the top of the cylinder the lower pin on the air-pump rod will have struck the spanner *m* upwards, and will thereby have closed the valves V′ and E and opened the valves V and E′. The piston will then be in the same situation as in the commencement, and will again descend, and so will continue to be driven upwards and downwards by the steam.

While this process is going on in the cylinder a quantity of warm water is formed in the condenser, by the mixture of condensed steam with the cold water admitted through the condensing jet I′. It has been shown (*see* STEAM) that any quantity of water in the state of steam being condensed by cold water, will raise nearly six times its own weight of cold water from the freezing to the boiling point by the latent heat which is rendered sensible in the process of condensation. But since the jet of cold water, instead of being at the temperature of melting ice, is at the common temperature of the atmosphere, say 50°, and it is necessary to reduce the temperature of the water in the condenser to at least 100° (otherwise steam would be produced by it, which would seriously resist the motion of the piston), and to reduce water from 212° to 100° by mixture with water at 50° would require a quantity of the latter about twice the former, it follows that the quantity admitted through the jet must be more than twenty times the quantity which passes through the cylinder in the form of steam.

The warm water which is thus formed in the condenser, if allowed to accumulate there, would soon choke it up and stop the action of the machine. To prevent this the air-pump is provided ; when the air-pump piston ascends it leaves below it a vacuum, and the *foot-valve* M being relieved from all pressure, the weight of the water in the condenser forces it open, and the warm water flows from the condenser into the lower part of the air-pump, from which its return to the condenser is prevented by the closed valve. When the air-pump piston descends its pressure on the liquid under it will force open the valve in it, through which the warm water will pass ; and when the piston descends to the bottom of the pump-barrel the warm water which was below it will pass above it, and cannot return, as the valves which open upwards will be kept closed by its weight. When the piston next ascends it will raise the water thus collected above it, and will throw it through the valve into the hot well K.

The hot-water pump L is usually a suction and forcing pump, and draws up the warm water from the hot well, and drives it through a pipe called the feed pipe to a cistern placed over the boiler, from which the boiler derives its feed of water. *See* STEAM BOILER.

The system of jointed rods *c d e f g*, called the parallel motion, have for their object the maintenance of the rods of the steam-piston and air-pump in a truly vertical position. The steam-piston rod imparts motion to the beam, and the air-pump rod receives motion from it. The beam, however, moving as it does alternately upwards and downwards on an axis, every point on it must move alternately in the arc of a circle whose centre is in the axis of the beam. If the ends of the rods of the steam-piston and air-pump were immediately attached to the beam, they would move therefore not in truly vertical straight lines, but in the arcs of circles, and by reason of the curvature of such arcs they would be alternately reflected to the right and to the left. Such an effect would be quite incompatible with that smoothness and precision which are essential to the effective action of the steam engine. By the parallel motion the ends of these piston rods are not immediately attached to the working beam ; a rod *c d*, called the *radius rod*, moves on a fixed centre *c* attached to the framing of the engine ; a bar *d b* connects the other end of this radius rod with a pivot *b* on the

beam, so that as the beam ascends and descends the pivots b and d each moves in an arc of a circle, and these pivots are thereby drawn aside, but always in contrary directions. These deflections of the ends of the bar $d\ b$ are neutralized at its middle point e, which neither deviates to the right nor to the left, but moves in a vertical straight line. To this point e the end of the air-pump piston is attached.

At the end of the beam to another joint f is attached a bar $f g$, equal to $b\ d$, connected by pivots with another beam $d g$ equal in length to $b f$, so as to form the jointed parallelogram $b\ d\ g\ f$. By this arrangement, as the beam ascends and descends the point g is moved in a manner altogether similar to the point e, only that it moves through a greater space in the proportion of the distance of g from the axis of the beam to that of e from the same point. The point g, therefore, to which the steam-piston is attached, is moved upwards and downwards in a truly vertical straight line, while the end f of the beam with which it is connected is moved upwards and downwards in the arc of a circle.

When the piston is at the top of the cylinder the crank G placed on the axis of the fly-wheel F is at its lowest position, and when the piston is at the bottom of the cylinder it is in its highest position. In each of these positions the action of the steam on the piston could not impart any motion to the crank; for the connecting rod O being then in line with the crank, any force given to it, being necessarily exerted in the direction of its length, would only produce a pressure or strain on the crank-pin without the least tendency to turn the crank round the axis of the fly-wheel. In these positions the machine is therefore placed in a dilemma, in which the moving power ceases to have any influence on the object it is intended to move.

The machine is extricated from this dilemma by the inertia of the fly-wheel; that wheel being a large mass of matter, having once received a certain velocity of rotation on its axis, has a tendency to retain such motion, and will, in fact, retain it until it has been deprived of it by the continued resistance of friction and the air. When, therefore, the crank arrives at either of the positions above mentioned and the moving power ceases to be effective, the inertia of the fly-wheel causes it to continue its motion, and the crank is immediately turned out of the extreme position it had assumed, and thrown into a position in which the power of the piston on it becomes effective.

The functions of the fly-wheel are, however, not confined to carrying the machine thus through the dead points by the energy of the force it has received from the piston when the crank was in a more favourable position; it likewise equalizes by the same property the unequal effect of the crank: it is only when the crank forms a right angle with the connecting rod that it is fully effective. As that angle changes its leverage changes, until at length the leverage is reduced to nothing at those extreme positions just mentioned. When the crank is in and near the position in which it is rectangular to the connecting rod, its action is shared between the fly-wheel and the machinery driven by the engine, a part being engaged in accelerating and therefore giving momentum to the fly-wheel. As it passes towards the dead points this momentum taken up by the fly-wheel is given back to the crank in aid of the moving power, at those positions of the crank where the effect of the moving power upon it becomes enfeebled. In this manner the fly-wheel in the steam engine becomes a perfect equalizer of the mechanical action of the machine.

Although the system of rods called the parallel motion appears in the figure to consist only of one parallelogram $b\ d\ g\ f$ and one rod $c\ d$, it is in fact *double*, a similar parallelogram and radius rod attached to corresponding points, and acting in the same manner on the other side of the beam; but from the view given in the cut, the one set of rods hides the other. The two systems of rods thus attached to the beam are connected by cross rods, the ends of which form the pivots or joints, and extend between the parallelograms. The ends of these cross rods only are visible in the figure. It is to the middle of one of these rods, the end of which is represented at e, that the air-pump piston is attached; and it is to the middle of another, the end of which is represented at g, that the steam-piston rod is attached. These two piston rods, therefore, are driven not by either of the parallelograms, but by the bars extending between them.

To the working end H of the beam is attached the *connecting rod* O, formed of cast iron, the lower end of which is attached to the crank G by a pivot. The weight of the connecting rod is made to balance the weight of the piston rods of the air-pump and cylinder, and the weight of the piston rod N of the cold water pump, balances the weight of the piston rod L of the hot water pump. Thus, so far as the weight of the moveable parts of the machine is concerned, the engine is in equilibrium, and the piston would rest indifferently in any position in the cylinder.

The axis of the fly-wheel on which the crank is formed is square in the middle, where the wheel is attached to it; but has cylindrical necks at each end, which rest in bearings supported by the framing of the machine, in which bearings the axis revolves freely. On the axis of the crank is placed the fly-wheel, and connected with its axle is the governor Q already described.

The manner in which the crank affects the connecting rod at the dead points already mentioned produces an effect of great importance in the operation of the engine. When the crank approaches the lowest point of its play, and at the same time the piston is approaching the top of the cylinder, the motion of the crank pin becomes nearly horizontal, and consequently its effect in drawing the connecting rod and the end of the beam downwards, and the piston upwards, is extremely small. The consequence of this is, that as the piston reaches the top of the cylinder its motion becomes very rapidly retarded; and as the motion of the crank pin at its lowest point is actually horizontal, the piston is brought to a state of rest by this gradually retarded motion. A similar effect is produced at the other dead point. This suspension of motion at each end of the stroke affords time for the process of condensation to be effected, so that when the moving power of the steam upon the piston can come into action the condensation shall be sufficiently complete. As the piston approaches the top of the cylinder, and its motion becomes slow, the working gear is made to open the lower exhausting valve; the steam enclosed in the cylinder below the piston, and which has just driven the piston upwards, presses usually with a force of about 17 lbs. per square inch, while the uncondensed vapour resists with a force of about 2 lbs. per square inch. The steam will therefore have a tendency to rush from the cylinder to the condenser through the open exhausting valve, with an excess of pressure amounting to 15 lbs. per square inch, while the piston pauses at the top of the cylinder. This process goes on; and when the piston has been made to descend by the motion of the fly-wheel a sufficient distance from the top of the cylinder to call the moving force of the steam into action, the exhaustion will be complete, and the pressure of the uncondensed vapour in the cylinder will become the same as in the condenser. The pressure of the steam, and of the uncondensed vapour, varies within certain limits, and therefore the amount here assigned to them must be taken merely as an example.

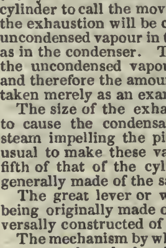
The size of the exhausting valves should be such as to cause the condensation to be completed when the steam impelling the piston is called into action. It is usual to make these valves with a diameter equal to a fifth of that of the cylinder, and the steam valves are generally made of the same magnitude.

The great lever or working *beam* was so called from being originally made of oak. It is now, however, universally constructed of cast iron.

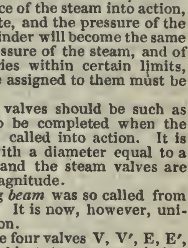
The mechanism by which the four valves V, V′, E, E′, are opened and closed, is subject to great varieties. Sometimes they are opened alternately in pairs by two distinct levers, and driven by two pieces attached to the air-pump rod; but more generally the admission of steam to the cylinder is regulated by a single moveable piece, called a *slide*.

Slides are very various in their form and arrangement; but that which has come into most general use is one which is called from the form of its cross section the D valve. This slide is represented in vertical section in figs. 2 and 3.

(2.)



(3.)

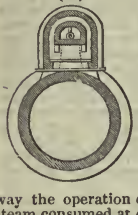


The rod E, by which the slide is moved, passes through a stuffing box F. The moveable piece or slide G is represented by a vertical section a, being a hollow passage through it extending from the top to the bottom; S is the mouth of the great steam pipe coming from the

boiler; P is the pipe leading to the condenser; T H is a hollow space formed within the slide, always in communication with the steam pipe S, and consequently always filled with steam from the boiler. A transverse section of the slide and cylinder is represented in fig. 4., where *a* represents the top of the passage marked *a* in fig. 2.

In the position of the slide represented in fig. 2. the steam filling the space T H has access to the top of the cylinder, but is excluded from the bottom. The steam which was below the piston, passing up the passage *a*, escapes through the tube P to the condenser. When the piston has descended the rod E moves the slide downwards, and throws it into the position represented in fig. 3. The steam in T H has now access to the bottom of the cylinder; while the steam above the piston, passing through P, escapes to the condenser. In this way the operation of the piston is continued, and the steam consumed at each stroke only exceeds the capacity of the cylinder by what is necessary to fill the passages between the slide and the cylinder. The steam filling the space T H has a tendency to press the slide back, so as to break the contact of the rubbing surfaces, and thereby to cause the steam to leak from the space T H to the back of the slide; this is counteracted by the packing *x* at the back of the slide.

(4.)

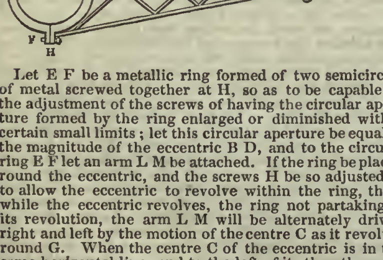


In engines of very long stroke, the extent of the rubbing surface of slides of this kind renders it difficult to keep them in steam-tight contact, and to ensure their uniform wear. In such cases, therefore, separate slides on the same principle are provided at the top and bottom of the cylinder, moved, however, by a single rod of communication.

A great variety of slides and cocks for regulating the admission of steam to the cylinder may be seen described in Dr. Lardner's work on the *Steam Engine*, p. 227—242.

The method of working the valves by pins attached to the air-pump rod already described has been, except in the case of engines of great magnitude and power, superseded by a contrivance called an *eccentric*, by means of which the slides or valves receive motion from the axle of the fly-wheel.

An eccentric is a metallic circle attached to the axle of the fly-wheel, so that its centre shall not coincide with the centre round which the axle revolves. Let us suppose that G (fig. 5.) is a square revolving shaft; let B D be a circular plate of metal, having a square hole cut in it through which the revolving shaft G passes; and let C be the centre of this circular plate. By the revolution of the shaft this centre C will be carried round it in a circle, the radius of which will be C G.



Let E F be a metallic ring formed of two semicircles of metal screwed together at H, so as to be capable by the adjustment of the screws of having the circular aperture formed by the ring enlarged or diminished within certain small limits; let this circular aperture be equal to the magnitude of the eccentric B D, and to the circular ring E F let an arm L M be attached. If the ring be placed round the eccentric, and the screws H be so adjusted as to allow the eccentric to revolve within the ring, then, while the eccentric revolves, the ring not partaking of its revolution, the arm L M will be alternately driven right and left by the motion of the centre C as it revolves round G. When the centre C of the eccentric is in the same horizontal line, and to the left of it, then the position of L M will be that which is represented in fig. 5. But after half a revolution of the main axle the centre C will be thrown to the right of G, and the point M will be moved to the right to a distance from its former position equal to twice C G. Thus, as the eccentric revolves, the ring, together with the arm L M, will be alternately driven right and left, through a space equal to twice the distance between the centre of the eccentric and the centre of the revolving shaft.

If we suppose a notch formed at the extremity of the arm L M, capable of embracing a lever N M moveable on a pivot at N, the motion of the eccentric would give to such a lever an alternate motion from right to left, and *vice versa.* If we suppose another lever N O connected with N M, and at right angles to it, forming what is called a *bell crank*, then the alternate motion of M from right to left will impart a corresponding motion upwards and downwards to the end O of the lever N O. If this last point O were attached to the vertical rod of the slide, it would move the slide upwards and downwards. The extent of this motion might be regulated at pleasure by varying the length of the arms of the levers, and the moment at which it would commence to move in either direction would be determined by the position of the eccentric on the fly-wheel shaft.

Expansive Engine.—As the operation of the steam engine has been explained, the power which moves the piston is the immediate force with which vapour is produced in the boiler. Each quantity of water which is successively evaporated obtains the space requisite for it in the form of steam, by pressing towards the cylinder an equal quantity of steam previously contained in the boiler; and it is the force with which the steam is thus pressed forward that impels the piston. But it has been shown (*see* STEAM) that great additional mechanical power will be obtained from the steam, if, besides this moving power which results from immediate evaporation, the expansive power of the steam separated from the water be used. This is accomplished by closing the valve through which steam flows from the boiler to the cylinder before the piston has completed its stroke. Thus, let us suppose that when the piston has advanced through half its stroke the steam valve be closed, the steam which is then acting upon the piston will still urge it forward; but as the piston advances, this steam assuming a proportionally augmented volume will acquire a gradually diminished pressure, so that through the remaining half of the stroke the piston will be urged by a pressure progressively decreasing, and at the termination of the stroke it will be a little less than half the force with which the piston was impelled while the steam valve was open.

Since the force of the steam from the moment the steam valve is closed is thus continually diminished, its moving power might be so much attenuated that it would be incapable of overcoming the resistance so as to complete the stroke; this would happen if the steam were cut off when only a small fraction of the stroke has been made, unless the pressure of the steam while the valve is open exceeds the resistance in a proportionate degree. It is for this reason that the expansive principle cannot be brought into operation to any considerable extent, unless steam be used of a greater pressure than is commonly adopted in low-pressure engines. It is also apparent that with an equal volume of cylinder greater length of stroke should be given when the expansive principle is used.

The mechanism by which the expansive principle is brought into practical operation consists merely in the adaptation of valves or slides which shall stop the admission of steam when the required fraction of the stroke has been made by the piston, but which shall leave the communication with the condenser open till the stroke is completed. If separate valves be used, this is accomplished by adapting the pins or other mechanism by which they are worked to open and close them independently of each other at the proper times. If slides be used, it is effected by regulating the form and aperture of the slide, so as to cover and uncover the passages to the cylinder at the proper times. Each species of valve, and each form of slide or cock, has its own peculiar provisions for accomplishing this, the details of which may be seen by a reference to *Lardner on the Steam Engine*, p. 232. *et. seq.*

Single-acting Steam Engine. — When the steam engine is applied to the purpose of pumping water, which in the first periods of its invention was its only practical application, the force which it exerts is only required in raising the pump rods with their load of water, their own weight being more than sufficient for their descent. As the pump rods are attached to the working end H (fig. 1.) of the beam, the force of the steam is only required to draw up that end, and therefore to draw down the end at which the steam piston is attached; the steam, therefore, being only required to press the piston downwards, it is not admitted from the boiler below it, as in the engine already described, which for distinction is called the double-acting engine. During the down stroke of the single-acting engine the performance of the machine is precisely similar to that already described; steam is admitted through the upper steam valve above the piston, while the space in the cylinder below the piston is kept in free communication with the condenser by keeping the lower exhausting valve open. The operation, therefore, of the upper steam valve, and the lower exhausting valve, is precisely the same as in the double-acting engine.

When the piston has reached the bottom of the cylinder, the two former valves being closed, a valve called the equilibrium valve is opened, by which a free communication is made between the top and bottom of the cylinder: by this means the steam which fills the upper part of the cylinder being allowed to flow equally to the lower part will press with the same force on both sides of the piston, and will therefore have no tendency whatever to move it. Under these circumstances the preponderating weight of the pump rods suspended from the other end of the beam will draw the piston to the top of the cylinder; while it is ascending the steam which was above will pass through the equilibrium valve below it, and when the piston has reached the top of the cylinder the cylinder under the piston will be filled with the same steam which previously had driven the piston down. In order to accomplish the next down stroke, the equilibrium valve is closed, and the upper steam valve and lower exhausting valve are opened; the steam pressure acts above the piston, and a vacuum is produced below it, and the piston descends as before.

Single-acting engines are frequently worked with expansion. In the application of this principle to them the upper steam valve is closed before the lower exhausting valve; but both these valves are open together. The mechanism for working the expansion valves does not materially differ in its principle from that already described in the double-acting engine.

The great theatre of the operation of single-acting engines is the mining districts, and especially that of Cornwall. The Cornish pumping engines are constructed of enormous power, and carry out the expansive principle to a great extent. Engines are there used for the drainage of mines with cylinders from 7 to 8 feet in diameter, and from 10 to 12 feet in the stroke. Steam having a pressure of from 20 to 30 lbs. per square inch, and upwards, is used for impelling them, and is cut off at a third or fourth of the stroke. A system of careful inspection has been for some years established by the mining companies, with a view to the improvement of the efficiency of the engines, and monthly reports of the performance of the engines have been regularly printed. The effect of this has been to stimulate the activity and skill of all concerned in the manufacture and working of these machines, and a rapidly progressive improvement in them has taken place. The efficiency of these engines is estimated by the number of pounds weight of water which they are capable of elevating one foot high by the combustion of a bushel of coals. This has been termed the *duty* of the engine. In 1769, when Mr. Watt first directed his attention to the steam engine, Smeaton computed that the average duty of the engines then in use was about 5½ millions; from that time to the year 1800, a period of thirty years, Mr. Watt's improvements in the steam engine were made, and the duty was gradually encreased to 20 millions, or very nearly quadrupled. In 1813, the system of inspection first mentioned was commenced, and the average duty was the same as in 1800. From this time to 1826, the engines underwent a progression of slow but steady improvements, and the duty was increased to 30 millions. This state of improvement continued; and, in 1828, the average duty had risen to nearly 77 millions. The increase since that time has been slower: the average duty for the last few years has been from 80 to 90 millions; but in one well-conducted experiment, it was found that by the combustion of a bushel of coals an amount of mechanical power was produced which raised the inconceivable load of 125 millions of pounds weight one foot high. Thus, by the improvements of Watt and their immediate consequences, the power of the steam engine was, within the space of seventy years, increased about 25 fold.

Non-condensing Steam Engines. — The form and structure of non-condensing engines differ in nothing from that of double-acting condensing engines, except in the absence of the condensing apparatus; that is to say, the condenser, the air-pump, and the cold water and hot water pumps. The steam, after it has impelled the piston, instead of being conducted to a cold vessel to be condensed, is simply allowed to escape into the atmosphere, and is commonly ejected into the chimney of the furnace.

The operation of such a machine is extremely simple. The valves by which the steam is admitted to, and allowed to escape from the cylinder, are exactly similar to those of the double acting engine. In the down stroke of the piston the upper steam valve being open admits steam from the boiler above the piston, and the lower exhausting valve allows the steam below it to escape through a tube which leads to the chimney, up which it rushes. In the up stroke, the lower steam valve being open admits steam from the boiler below the piston, and the upper exhausting valve being open allows the steam above the piston to escape to the chimney.

It is evident, in such a machine, that the piston is always resisted by the pressure of the steam escaping to the chimney. As such escape cannot be effected except by steam of greater pressure than that of the atmosphere, it follows that the piston is always resisted by a force somewhat greater than the atmospheric pressure. The steam which urges the piston is therefore only effective by the excess of its pressure above that of the escaping vapour, which may be taken at about 16 lbs. per inch, but which varies in different engines.

As the steam used in non-condensing engines must, of necessity, have a pressure considerably exceeding that of the atmosphere, such machines have been generally called *high-pressure engines;* while those which condense the steam have been, on the other hand, called *low-pressure engines.* These terms are not, however, correctly expressive of the nature of these engines respectively. Many engines in which condensation is used, especially those in which the expansive principle is applied with much effect, are worked with steam of a high pressure, not unfrequently with a pressure amounting to from two to three atmospheres. It is therefore not correct to call such machines low-pressure engines. It is, however, true that engines worked without condensation must, of necessity, be worked by steam of a pressure which is generally called *high pressure.*

All locomotive engines, without exception, used on railways or common roads, are high-pressure non-condensing engines. *See* Locomotive Engine and Steam Carriage.

High-pressure non-condensing engines are almost universally used for inland navigation in the United States. *See* Steam Navigation.

Rotatory Steam Engine. — This term is sometimes applied to the double-acting engine working a crank and fly-wheel, as distinguishing it from the single-acting engine used for pumping. But it is more properly applied to an engine in which a motion of rotation is produced immediately by the action of the steam, without the intervention of such mechanism as the working beam, crank, and fly-wheel. This is usually effected by a piston which, instead of moving longitudinally in the cylinder, revolves within the cylinder on an axis which coincides with the geometrical axis of the cylinder itself. The mechanism is so contrived that this piston shall revolve in steam-tight contact with the sides and ends of the cylinder; and that while steam from the boiler constantly presses it on one side, the steam on the other side shall continually escape to the condenser, if it be a condensing engine, or to the chimney, if it be a non-condensing engine. The various contrivances for rotatory engines which have been suggested differ one from the other only in the mechanical expedients by which these ends are attained. Such machines are very numerous and various; but as none of them have yet been found to be attended with sufficient practical advantages to force them into any use beyond the experimental trials of their inventors, it is sufficient here to have indicated the general principle of their structure.

Atmospheric Engine. — The engine so called was the first form of steam engine which was ever brought into extensive and durable practical application; and in districts where fuel is cheap and abundant the simplicity of its structure still keeps it in partial use. Steam, in the atmospheric engine, is only used as an agent for the production of a vacuum, in order to give effect to the atmospheric pressure.

The atmospheric engine, which is only applied to pumping, consists of a cylinder open at the top, having a piston which moves in it air-tight and steam-tight. The piston is thus maintained by being lubricated by oil or melted tallow poured above it. Supposing the piston to be at the bottom of the cylinder, steam is admitted from the boiler by a proper valve. This steam, having a pressure not much exceeding that of the atmosphere, will balance the pressure of the atmosphere above the piston, and will be sufficient also to overcome the friction of the piston with the cylinder. Under such circumstances the preponderating weight of the pump-rod at the other end of the beam draws the piston to the top of the cylinder, in the same manner as the piston is drawn up in the single-acting steam engine already described. The piston being thus suspended at the top of the cylinder, the valve admitting steam from the boiler is closed, and another valve or cock is opened, by which a jet of cold water is thrown into the cylinder. This immediately condenses the steam, and leaves a vacuum under the piston. The atmospheric pressure above it consequently takes effect, and forcing the piston to the bottom of the cylinder, draws the pump-rods, with their load of water, up. When the piston arrives at the bottom of the cylinder, the cock admitting the jet of cold water is closed and another is opened, by which the warm water formed by the mixture of the condensed steam with the cold water of the jet is discharged into a reservoir from which the boiler of the engine is fed. The steam is then again admitted from the boiler, the piston ascends, and so the process is continued.

The cocks or valves above mentioned are opened and closed at the proper times by means of a rod or beam,

called the *plug frame*, attached to the working beam, which is placed and which moves in a manner similar to the rod of the air-pump in the steam engines already described.

History of the Steam Engine. — Various attempts at the mechanical application of steam on a small scale were made at very early periods in the history of mechanical science. Hero of Alexandria has left a description of a small machine, in which a motion of continued rotation was imparted to an axis by the reaction of steam issuing from lateral orifices in arms placed at right angles to the revolving axis. The date of this invention is about a century before the birth of Christ. Branca, an Italian engineer, about the beginning of the 17th century, proposed to give motion to a wheel by a blast of steam blown against its axis; and about the same period De Caus, a French engineer, described a machine by which a column of water might be raised by a pressure of steam confined in the vessel above the water to be elevated. There is nothing, however, in the descriptions and developments which these projectors have left, to demonstrate that they were acquainted with those physical properties of elasticity and condensation (*see* STEAM) on which all the power of steam, as a mechanical agent, depends. In the middle of the 17th century, or somewhat later, the celebrated Marquis of Worcester published in his work, called *A Century of Inventions*, a description of a steam engine to be worked by steam of high pressure, which, though not minute and explicit in its details, is still such as it is difficult to conceive being written by any one unacquainted with the elastic force of steam. (See *Lardner on the Steam Engine*, p. 23. *et seq.*) Towards the close of that century, Papin, a French engineer, who was employed by the Landgrave of Hesse, in Germany, and was professor of mathematics at Marbourg, directed his attention to the properties of steam, and conceived the idea of obtaining a moving power by introducing a piston into a cylinder and producing a vacuum under it by the sudden condensation of steam by coal. In fact, he conceived the notion of the principle of the atmospheric engine; but there is no evidence of his having carried that or any other machine into practical application, even so far as the construction of a model, until after machines worked by steam had been constructed elsewhere.

The first actual working steam engine of which there is any record was invented and constructed by Thomas Savery, an Englishman, to whom a patent was granted for it in the year 1698. Savery reproduced the method of forming a vacuum by the condensation of steam, apparently without being aware of the paper written by Papin. He combined this with the elastic pressure of steam as applied by Lord Worcester, and constructed an engine, which, for a time, was used to a considerable extent for raising water. Papin's steam engine consisted of a strong iron vessel formed in the shape of an egg, having a tube or pipe at the bottom, which descended to the place from which the water was to be drawn, and another at the top, which ascended to the place to which it was to be elevated. This oval vessel was filled with steam supplied from a boiler, by which the atmospheric air by which it was previously filled was first blown out of it. When the atmospheric air was thus expelled, and nothing but pure steam was left in the vessel, the communication with the boiler was cut off, and cold water was poured on the external surface of the vessel. The steam within it was thus condensed and a vacuum produced, and the water was drawn up from below in the usual way by suction. The oval steam vessel was thus filled with water; a cock at the top of the lower pipe was then closed, and steam was introduced from the boiler into the oval vessel above the surface of the water. This steam being of high pressure, forced the water up the ascending tube, from the top of which it was discharged; and the oval vessel being thus again filled with steam, the vacuum was again produced by condensation, and the same process was repeated by using two oval steam vessels which would act alternately; one drawing water from below, while the other was forcing it upwards, an uninterrupted discharge of water was produced.

Owing to the danger of explosion, from the high pressure of the steam which was used, and from the enormous waste of heat by unnecessary condensation, these engines soon fell into disuse.

The demand for a moving power for the drainage of the mines less expensive and more efficacious than that of horses, which was then generally used, became at this time pressing, and probably led to the invention of the atmospheric engine already described. This machine was invented by Newcomen, a blacksmith, and Cawley, a glazier, at Dartmouth, in Devonshire. In the first engine constructed by them the condensation was effected by the affusion of cold water upon the external surface of the cylinder, which was introduced into a hollow casing by which it was surrounded: the discovery of condensation by jet within the cylinder, one of the most important steps in the improvement of the steam engine, was accidental. It happened that a small hole occurred in the bottom of the cylinder of an engine, by which the water let in to cool its external surface oozed in, forming a little jet. The effect was a much more rapid and perfect condensation than ever was or could be effected by external cold. Thenceforward, the method of condensation by jet was adopted, and has ever since been used.

In the early atmospheric engines, the cocks by which the steam was admitted and condensed, and by which the injected water and condensed steam were drawn off, were worked by hand; and as the labour was light and monotonous, and required no skill, boys were employed for the purpose, called *cock boys*. It happened that a cock boy, by name Potter, having an itch for play, and endowed with more ingenuity than industry, imagined that by tying strings to the cocks, and connecting them with the working beam above the cylinder, regulating the action by carrying them under or over certain pipes, he could make the beam, as it ascended and descended, open and close the cocks more regularly and effectually than he found himself able to do. This he accordingly accomplished, and was habitually absent from the engine-house, enjoying himself with his playfellows, when his employers were giving him credit for most extraordinary industry and regularity in the discharge of his duties. The engine, in fact, by this expedient, nearly tripled its efficacy. Thus, by the ingenuity of a child, the steam engine was first endowed with those qualities of an automaton which have ever since rendered it an object of admiration and interest. The atmospheric engine, thus improved, held its place as the great instrument for the drainage of mines until the epoch which was rendered memorable by the inventions and discoveries of the immortal Watt.

Watt was a mathematical instrument maker in Glasgow; and, being employed by the university of that place, it chanced, about the year 1763, that the model of an atmospheric engine used at the lectures of the professor of natural philosophy required some repairs, to make which it was placed in the hands of Watt. In the experiments which it became his duty to make with this model, he was struck with the fact that the quantity of steam it consumed for each stroke of the piston was many times more than the contents of the cylinder. The large quantity of water necessary to be injected in order to complete the condensation also excited his surprise. This led him to make experiments, by which he soon arrived at the discovery of some of the most important phenomena connected with the evaporation of water. He made a near approximation to the proportion of the volume of steam to that of water. He ascertained with great precision the latent heat of steam, and consequently determined the quantity of water necessary to condense any given quantity of steam. Filled with astonishment at these results, and more particularly at the nature of latent heat, and at the great amount of the latent heat of steam, he repaired to Dr. Black, then professor of natural philosophy in the university, and communicated to him the result of his discoveries. He then, for the first time, learned Black's celebrated theory of latent heat, and found that he had himself thus accidentally discovered one of the most striking facts on which that theory rested.

Considering the atmospheric engine in an economical point of view, Watt was forcibly impressed with the waste of expense which appeared to arise in the unnecessary consumption of steam involved in its operation. In the theory of that engine, one cylinderful of steam ought to be sufficient for each stroke of the piston. Watt, on the other hand, found that the actual consumption was at the rate of four or five cylinderfuls per stroke. On examination, he discovered the source of this waste to arise from the necessity, in order to make the piston ascend, not only to condense the steam, but to cool the whole mass of the cylinder down to 100°; and, to make the piston descend, it was necessary not only to fill the cylinder with steam, but to raise the temperature of the cylinder and piston from 100° to 212°. He soon perceived that this enormous waste of fuel was the inevitable consequence of condensing the steam in the cylinder.

Reflection on these circumstances happily led him to the idea of condensing the steam in a separate vessel, which should be kept immersed in a cistern of cold water, and in which a jet of cold water might be kept constantly playing, with the addition of a pump to draw off the injected water and condensed steam from such vessel. In fact, all the details of the steam engine as already described were soon carried into practical effect, and engines constructed according to these principles.

At the time of this invention the steam engine had never been used, except for the purpose of raising water. It became a substitute for horse power in working pumps. Although Watt perceived, in the first instance, the ease with which it might be adapted as a general moving power, his first efforts were to get it adopted in the mining districts for drainage. His first engines were, accordingly, the single-acting engine above described;

and it was not until about the year 1784 that he took a patent for the double-acting engine, which is adapted to give a motion of rotation to a shaft, and therefore capable of giving motion to every kind of mill work.

Notwithstanding the manifest advantages attending these improvements of Watt, the mining and manufacturing interests were slow and reluctant in their adoption of them; and, at the end of twenty years from the date of his first improvement, Watt and his partners found that the manufacture of the steam engine had not only not been a source of commercial profit, but had entailed upon them a loss of capital to the amount of about 50,000*l*. An application was made to parliament, on this ground, for an extension of the patent, which was, after much opposition, granted till the year 1800. Various improvements in the more minute details of the machinery of the engine succeeded this; and Watt lived to reap an ample reward for his ingenuity and perseverance, and to be acknowledged as one of the greatest benefactors of the human race.

The engine, as applied to drainage and to manufactures, has received no important improvement in its principle since it was dismissed from the hands of Watt. Those principles which he suggested and applied have been carried out to their fullest extent, and the efficiency of the engine has been proportionally increased. The engine has been successfully adapted to navigation. For an account of application to that purpose, see STEAM NAVIGATION.

For the details of the form and construction of the boilers by which steam is generated, and from which it is supplied to the different kinds of engines, see STEAM BOILER.

For further and more minute details respecting the structure and operation of steam engines of every variety of form, and respecting the history of the invention and progressive improvement of the steam engine, see *Lardner on the Steam Engine*, 7th edition, London, 1846.

STEAM GUN. A contrivance by which balls, or other projectiles used in warlike operations, may be projected by the expansive force of steam.

This invention, which is due to Mr. Jacob Perkins, so well known for various ingenious and useful contrivances in the mechanical arts, having been first brought forward since the general peace which succeeded the battle of Waterloo, has never been submitted to the test of actual experience either in military or naval operations, and consequently has not received the benefit of that stimulus to improvement which is always so necessary to bring mechanical contrivances of a novel kind to perfection, and which can only be derived from their practical application on a large scale. Of the probable or possible utility of the steam gun nothing, therefore, can be inferred from that safest source of information — experience; and we are left to judge of it by the general properties of vapour, and by the experiments on a small scale to which it has been submitted.

If a strong close iron vessel, having two valves, one opening inwards and the other outwards, the latter being loaded with some definite pressure, be *completely* filled with water, such a vessel may be heated to the temperature corresponding to the pressure with which the valve is loaded without causing any portion of the water in it to be converted into steam. To render the effect more easily understood, let us suppose that the valve is loaded with a pressure of fifty atmospheres. The temperature of water evaporated under that pressure being 510° (*see* STEAM), the vessel may be raised to any temperature not exceeding 500°, without having any of the water contained in it converted into steam. If the temperature to which the water is raised be 500°, and a cubic inch of water at common temperature be forced into the vessel through the valve which opens inwards, water being sensibly incompressible, a cubic inch of water at 500° will be forced out at the valve which opens outwards. This water being no longer subjected to the pressure which kept it in the liquid state, will suddenly expand and flash into steam, which at first will have a pressure of 45 atmospheres, but as it expands will have its pressure diminished in nearly the same proportion as the volume into which it swells shall be increased. Since, however, 500° is not sufficient heat to enable the whole of the water thus ejected to pass into steam (*see* STEAM), that part of it which will take the vaporous form will take the requisite amount of latent heat from the sensible heat of that portion which remains in the liquid state. As this latter portion will still retain a considerable temperature, it may be conducted to a vessel containing the feed for the heated vessel just mentioned, from which it will be again forced into that vessel.

Such was the principle of Mr. Perkins's *generators;* by which term he denominated those close vessels in which water was raised to a high temperature without being converted into steam.

Now if the valve through which the heated water is ejected be supposed to be in communication with the barrel of a gun or piece of ordnance, in the same manner as the barrel of an air gun is in communication with the hollow metallic ball in which air is compressed, a ball may be projected by the expansive force of the water ejected from the valve, in the same manner exactly as the ball of an air gun is projected by the expansive force of the compressed air.

As the water may be ejected from the valve either in a constant stream or by a rapid succession of jets, the balls may be discharged from the barrel as rapidly as it is possible for them to be brought under the action of the steam; and since the heating of the barrel only tends to increase the elastic force of the steam, there appears to be no other practical limit to the action of such an engine of offence except that which may be imposed on the heating power applied to the generator.

Of the abstract practicability of applying steam in this manner as an offensive engine there can be no doubt. Both theory and experiment conspire to establish it; but of the comparative efficacy, convenience, and economy of it, compared with gunpowder, many doubts will present themselves to all who duly reflect on the circumstances and purposes of war on the one hand, and the phenomena attending the explosion of gunpowder and the evaporation of water on the other. Not to mention any other, the fact that the steam gun cannot be brought into action until the generator has been raised to a high temperature by the application of an adequate furnace, would at once give to gunpowder an advantage over steam which would limit the application of the latter to a very few cases indeed, such as those of siege and other protracted military operations. In naval warfare it might possibly be more frequently available; but even in that case, great improvements in the details of its mechanism should be made before its use could be attempted with any reasonable prospect of advantage.

The steam gun is exhibited on a small scale in most mechanical museums and other exhibitions of a like kind; and such will probably be the limit of its use for a long period to come.

STEAM NAVIGATION. The art of applying the power of steam to the propulsion of boats and vessels in general, as well for inland communication by rivers and lakes, as for the general purposes of national commerce on the seas and oceans by which the various parts of the globe are separated.

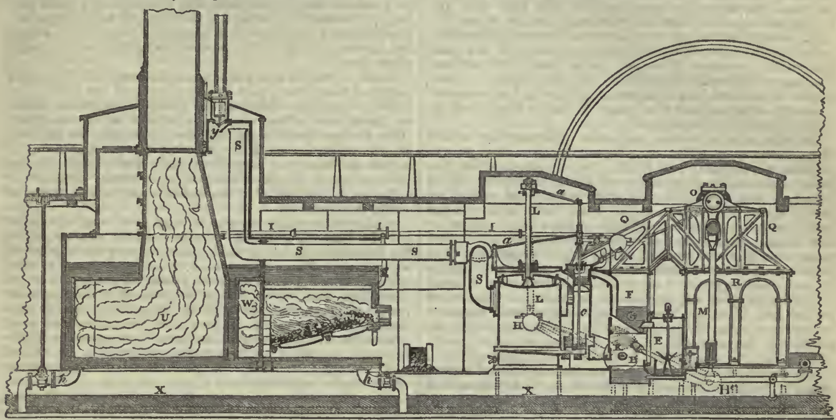
The manner in which the steam engine is rendered an instrument for the propulsion of vessels must, in its general features, be so familiar to every one as to require but short explanation. A shaft is carried across the vessel, being continued on either side beyond the timbers; to the extremities of this shaft on the outside of the vessel are attached a pair of wheels, constructed like under-shot water wheels, having fixed upon their rims a number of flat boards called *paddle boards*. As the wheels revolve, these paddle boards strike the water, driving it in a direction contrary to that in which it is intended the vessel shall be propelled. The moving force imparted to the water thus driven backwards by reaction on the vessel propels it. On the paddle shaft are constructed two cranks or winches, placed at right angles one to the other, so that whenever one of them is thrown into the highest or lowest position the other is horizontal. These cranks are worked by strong iron rods called *connecting rods*, which are themselves either driven directly by the pistons of two steam engines, or are worked by those pistons; thus the medium of working becomes similar to those used in the ordinary land engines. (*See* STEAM ENGINE.) The two cranks being placed at right angles, it follows that when one piston is at the top or bottom of its stroke, and the crank driven by it in the highest or lowest position, the other will be at the middle of its stroke, and the crank driven by it will be in the horizontal position. One of the pistons is therefore always in a position to produce the most advantageous effect on the crank at the moment that the other piston loses all power over the crank driven by it; and in the same manner it may be seen that while the power of one piston is augmented from zero to its greatest effect, the power of the other is decreasing from its greatest effect to zero. Thus the combined action of the two pistons is nearly uniform in its efficiency. If one engine only were used the motion of the wheels would be unequal, being most rapid when the piston is at the middle of the stroke and slowest at the extremities.

The steam engines used for navigation may be either condensing engines or non-condensing engines. If the latter are used, steam must be used having a pressure above the atmosphere of from 15 to 20 lbs. per square inch. Boilers in which steam is produced under this pressure are considered in Europe so unsafe, that non-condensing engines with low-pressure boilers are almost universally used for navigation. In America, however, high-pressure boilers with non-condensing engines are generally used.

The arrangement of the parts of marine engines is different in several respects from land engines. Steam

vessels being generally employed to navigate the open seas, and being, therefore, subject to the vicissitudes of tempestuous weather, the machinery must be protected by being placed below the deck. The space allotted to it being thus limited, great compactness is necessary. The paddle shaft being very little below the deck, the working beam and connecting rod could not be placed above it. The beam is therefore placed below the cylinder, and is driven by the pistons by means of a cross head attached to the piston rod, from the ends of which the rods of the parallel motion (*see* STEAM ENGINE) are carried downwards to the end of the beam. From the other end of the beam the connecting rod is presented upwards towards the crank.

The general arrangement of the parts of a marine engine will be easily understood by reference to the figure, in which is represented in section a marine engine with its boiler, as placed in a steam vessel. The



sleepers of oak supporting the engine are represented at X; the base of the engine is secured to these by bolts passing through them and the bottom timbers of the vessel. S is the steam pipe leading from the steam chest in the boiler to the slides *c*, by which it is admitted to the top and bottom of the cylinder. The condenser is represented at B, and the air-pump at E. The hot well is seen at F, from which the feed is taken from the boiler. L is the piston rod connected by the parallel motion *a* with the beam H, working on a centre K near the base of the engine. The other end of the beam H drives the connecting rod M, which extends upwards to the crank, which it works upon the paddle shaft O. The framing by which the engine is supported is represented at Q R.

The nature and operation of the several parts just mentioned will be understood by reference to the explanation of the structure and operation of the double-acting steam engine, given under the head STEAM ENGINE; for, in fact, the marine engine, such as is here represented, is nothing more than a double-acting condensing steam engine, adapted in its form to the circumstances in which it is used in navigation.

The beam exhibited in the figure is shown in dotted lines, as being on the further side of the engine. A similar beam similarly placed, and moving on the same centres, must be understood to be at this side, connected with the cross head of the piston in like manner by a parallel motion, and with a cross piece attached to the lower end of the connecting rod and to the opposite beam. The eccentric, which works the slides, is placed upon the paddle shaft O; and the connecting arm which drives the slides may be easily detached when the engine requires to be stopped. The section of the boiler grate and flues is represented at W U. The safety valve *y* is enclosed beneath a pipe carried up beside the chimney, and is inaccessible to the engine-man. The cocks for blowing aft the salt water from the boiler (a process which we shall presently explain) are represented at *h*, and the feed pipe at I. Those parts will be fully understood by reference to the explanation given under the head STEAM BOILER.

To save space, marine boilers are constructed so as to produce, within the smallest possible dimensions, the necessary quantity of steam. With this view a more extensive surface in proportion to the capacity of the boiler is exposed to the fire. The flues by which the flame and heated air are conducted to the chimney are so constructed, that the heat shall act upon the water on every side in thin oblong shells or plates. This is accomplished by constructing them so as to traverse the boiler backwards and forwards several times before they issue into the chimney. The bottom of the boiler is not, therefore, one uniform flat or arched surface, as in land boilers; but is divided by a number of plates placed in a vertical position side by side, having spaces between them alternately appropriated to the water to be heated and the air from the fire. This division is in some boilers not only made in the bottom on a level nearly with the furnace, but another stratum of similar flues and water spaces is constructed above the level of the furnace; so that the heated air first traverses the lower stratum of flues, and afterwards, being conducted upwards, traverses the upper stratum before it issues into the chimneys.

In steam vessels, instead of effecting the necessary evaporation by a single boiler, it is usual to provide two, three, four, or more independent boilers, according to the magnitude of the vessel and the power of her engines. By this means, when at sea, the engines may be worked by some of the boilers while others are being cleaned or repaired.

The greatest inconvenience and difficulty attending the application of the steam engine to navigation arises from the necessity of supplying the boilers with sea water. This water is injected into the condenser for the purpose of condensing the steam, and it is thence mixed with the condensed steam conducted as feeding water into the boiler. Sea water holds in solution certain alkaline substances, of which the principal is muriate of soda, or common salt. This forms about three per cent. of the water. This salt not being evaporated with the water, remains in the boiler, and enters into solution with the water remaining in it, rendering that water a solution more and more concentrated the longer the boiler is worked. At length the water in the boiler becoming saturated, the salt will begin to be precipitated in the form of sediment; and if this were continued, the boiler would finally be filled with salt.

Besides the deposition of salt in a loose form, some of the alkaline substances have an attraction for iron, and a crust is thereby formed on the inside of the boiler. This crust obstructing the passage of heat from the fire to the water, gives the boiler plates an undue or unequal temperature, causes them to open in the seams, and softens them, so as to expose the boiler to a liability to leak or even to burst.

These effects can only be prevented by either of two methods: 1st, by so regulating the feed of the boiler that the water it contains shall not be suffered to reach the point of saturation, but shall be so limited in its saltness that no injurious incrustation or deposit shall be found; 2ndly, by the adoption of some means by which the boiler may be worked by fresh water. This end can only be attained by condensing the steam by a jet of fresh water, and working the boiler always by the same water.

The method by which the water is prevented from being over salted has been usually to discharge into the sea a certain quantity of over-salted water (called *brine*), and to supply its place by sea water introduced through the condenser, and which, being mixed with the condensed steam, is rather less salted than ordinary sea water. To effect this cocks, called *blow-off cocks*, are placed in the lower part of the boiler where the brine collects. The pressure of the steam is sufficient to force the lower strata of water out through these cocks when they are open, and this process is called *blowing out*. It is, or ought to be practised, at such intervals as will prevent the water from becoming over salted.

The improper observance of this process is attended with injurious effects at sea. If too much water be blown out, a proportionate loss of heat and waste of fuel is incurred. If insufficient water be blown out, incrustation takes place, and its injurious consequences ensue. The Messrs. Seaward of Limehouse use a glass hydrometer gauge, to indicate the saltness of the water in the boiler by showing its increase of density compared with ordinary sea water. A vessel containing one ton of water is placed so as to communicate on one side with the boiler, and on the other with the sea. In this vessel is a cock, which turned in one direction *opens* the communication with the boiler, and *closes* that with the sea; and turned in the other direction *opens* that with the sea, and *closes* that with the boiler. By this means the engineer is enabled to discharge a definite and ascertained quantity of brine, and the gauge indicates when a sufficiency has been discharged.

But the most effectual method of keeping the boilers from being over salted is by means of the *brine pumps* of Messrs. Maudslay and Field. This method, which has been successfully applied in the Great Western (plying between Bristol and New York), consists of pumps by which water is drawn from the lower parts of the boiler and driven into the sea. These pumps are worked by the engine, and their operation is constant. The feed pumps are likewise worked by the engine; and they bear such a proportion to the brine pumps, that the quantity of salt discharged in a given time in the brine is equal to the quantity of salt introduced in solution by the water of the feed pumps. By these means the same quantity of salt is constantly maintained in the boiler, and consequently the strength of the solution remains invariable.

To save the heat of the brine, the current of heated brine is conducted from the boiler through a tube, which is contained within that by which the feed is introduced. The warm current of brine, therefore, as it passes out, imparts a considerable portion of its heat to the cold feed which comes in; and it is found by this expedient that the brine discharged into the sea may be reduced to the temperature of 100°.

This expedient is so effectual that where the apparatus is properly constructed, and kept in a state of efficiency, it may be regarded as nearly a perfect preventive against incrustation.

A method of condensing the steam without a jet, by cold surfaces, was practised by Mr. Watt, but abandoned because its effect was not sufficiently instantaneous. This was revived by Mr. Samuel Hall of Basford, with a view to working marine boilers with fresh water. The steam from the cylinder was drawn through a great number of small tubes, which were constantly surrounded by cold water. Being by this means condensed, without being mixed with any injected water, it was carried to the feeding cistern to be reconducted to the boiler. In this manner the same water circulated constantly through the boiler, condenser, and feeding cistern, and it was only necessary to make good the waste produced by leakage. The same supply of fresh water, therefore, would always work the boiler, the very small quantity of waste being made good by the distillation of sea water.

These condensers were adopted in several steam vessels. In some they were abandoned after the experience of a few months; and the results have failed to produce their use to any considerable extent, notwithstanding that the object their projector professed to attain was admitted to be one of great importance.

One of the remedies proposed against incrustation was the use of copper boilers. The attraction which produces the adhesion of the calcareous matter to the surface of iron has no existence in copper, and all the saline matter precipitated in a copper boiler will therefore pass away through the blow-off cocks. Besides the injuries attending incrustation, an evil of another kind attends the accumulation of soot mixed with salt in the flues. In the seams of the boiler there are always numerous apertures of dimensions so small as to be incapable of being rendered staunch by any practicable means, through which the water within the boiler filters, and the salt which it carries with it, mixed with the soot, forming a compound which rapidly corrodes the boilers. The evil is not removed by copper boilers, in which it equally prevails.

As the voyages accomplished by steam vessels have increased in length, the economy of fuel in working them has become a subject of vastly augmented importance. So long as steam navigation was confined to river or channel transport, or to coasting voyages, the speed of the vessel was a paramount consideration, at whatever expenditure of fuel it might be obtained; but since steam navigation has been extended to ocean voyages, where coals must be transported sufficient to keep the engine in operation for a long period of time without a fresh relay, greater attention has been bestowed on economising it. Since the resistance of a steam vessel to the moving power produced by the action of the paddle wheels varies with the state of the weather, the consumption of steam in the cylinders must undergo a corresponding variation; and if the production of steam in the boilers be not proportioned to this, the engines will either work with less efficiency than they might do under the actual circumstances of the weather, or more steam will be produced than the cylinders can consume, and the surplus will be discharged to waste through the safety valves. The firemen of a marine engine must therefore in a certain degree discharge the functions of a self-regulating furnace, rendering the force of the fire always proportionate to the wants of the engine. None but the most industrious and skilful stokers can be expected to accomplish this.

Until within a few years of the present time the heat radiated from every part of the surface of the boiler was allowed to go to waste, and to produce injurious effects on those parts of the vessel to which it was transmitted. This evil has been lately removed by coating the exterior of the boilers with felt, prepared for the purpose, by which the escape of heat from the surface of the boiler is very nearly if not altogether prevented. This felt is attached to the plates of the boiler by a thick covering of white and red lead.

A form of marine engine was some years ago proposed by Mr. Thomas Howard, in which steam was produced by projecting water in small quantities on the surface of a piece of mercury maintained at a temperature of from 400° to 500°. The steam thus produced contained much more heat than was necessary to sustain it in the vaporous form. The engine was worked expansively, and by condensation; but as the project does not appear to have produced any practical consequences of permanent importance, we need not here notice it further.

The method by which the greatest amount of practical effect can be obtained from a given quantity of fuel must mainly depend on the extended application of the expansive principle. (*See* STEAM, STEAM ENGINE.) The difficulty of the application of this principle in marine engines has arisen from the objections entertained in Europe against the use of steam of high pressure under the circumstances in which an engine must be worked at sea. To apply the expansive principle with great effect, it is necessary that the moving power at the commencement of the stroke shall considerably exceed the resistance, its force being gradually attenuated till the completion of the stroke, when it will finally become less than the resistance. This condition may be fulfilled without resorting to steam of high pressure, if a sufficient quantity of piston surface be used. This method of rendering the expansive principle available for navigation, and compatible with low-pressure steam, has recently been brought into operation by Messrs. Maudslay and Field. Their improvement consists in adapting two steam cylinders in one engine to work a single crank, both pistons ascending and descending together, the piston rods being both attached to the same horizontal cross head moving in guides.

Mr. Francis Humphrys has obtained a patent for a form of marine engine, by which some simplification in the machinery is attained, and the same power comprised within more limited dimensions, a matter of great moment in long voyages. In this engine, there is attached to the piston of the cylinder, instead of a piston rod, a hollow casing, which moves through a stuffing box in the cover of the cylinder. The cross section of this casing is a very narrow and elongated ellipse, extending across the cylinder, or rather a long narrow slit with rounded ends. One end of the connecting rod is attached immediately to the centre of the piston, while the other end is attached to the crank placed above the cylinder; the connecting rod, therefore, works within the casing just mentioned; and instead of being, as usual, driven by a piston rod, it is driven by the *piston itself*.

To obtain from the moving power its full amount of mechanical effect, it would be necessary that it should be exerted against the water in a horizontal direction, and with a motion contrary to the course of the vessel. No system of mechanical propellers has, however, yet been contrived capable of perfectly accomplishing this; patents have been granted for numerous ingenious mechanical combinations to impart to the propelling surfaces such angles as appear to the respective contrivers to be the most advantageous. In most of these, the complexity has been a fatal objection. No part of the machinery of a steam vessel is so liable to become deranged at sea as the paddle wheels; and therefore that simplicity of construction which is compatible with those repairs which are possible on such emergencies is quite essential for safe practical use.

In the ordinary paddle wheel, the paddle boards have the planes so placed as to radiate from the axle of the wheel. In fact, the geometrical axis of the wheel is the common line of intersection of the planes of all the paddle boards. On entering and leaving the water, therefore, these boards will be oblique to the water, and this obliquity will be increased with the immersion of the wheels.

When the vessel is in proper trim, the immersion should be equal to the depth of the lowest paddle board; and if this immersion can be preserved unaltered, nearly the whole of the propelling power will be effective with the common wheels. In river navigation, or in general in smooth water, and when the trip is so limited that the fuel consumed has no sensible effect on the immersion, this steady immersion may be preserved, and in such cases the common wheel is a highly advantageous propeller; but in a heavy rolling sea, the motion of the vessel will produce a constant change of immersion in the wheels, and in long voyages the fuel consumed will lighten the vessel, so as to produce a considerable change in her trim.

To remove this inconvenience, and economize as much as possible the propelling effect of the paddle boards, it would be necessary so to construct them that they may enter and leave the water edgeways, or as nearly so as possible: such an arrangement would be, in effect, equivalent to the process called feathering, as applied to rowing. Any mechanism which would effectually accomplish this would cause the paddles to work in almost perfect silence, and would very nearly remove the inconvenient and injurious vibration which is produced by the action of the common paddles. But the construction of feathering paddles is attended with great difficulty under the peculiar circumstances in which such wheels work. Any mechanism so complex that it could not be easily repaired with such implements and skill as can be obtained at sea would be attended with great objections, and the efficiency of its propelling action would not compensate for the damages which must attend the helpless state of a steamer deprived of her propelling agents.

Feathering paddles have been projected by a vast number of ingenious persons, and a greater number of patents have been granted for this than perhaps for any other contrivance whatever connected with the application of steam power to the useful arts; yet it is remarkable that in no case has there been so signal a failure in attaining the desired end. Some inventors have failed by not clearly understanding the mechanical conditions to be fulfilled by a perfect wheel, and others by the complexity and expense attending the construction of the wheels they proposed. The common paddle wheel, with very slight modifications, still maintains its place as the almost universal propelling instrument for steam vessels.

About the year 1832, a paddle wheel, with mechanism for shifting the paddle boards as the wheel revolved, was brought into partial use in the admiralty steam vessels. This was called Morgan's paddle wheel: the inventor was Elijah Galloway. Its propelling effect in a rough sea was found to be superior to the common wheel, but in smooth water the difference was not considerable. The expense of this wheel excluded it altogether from commercial vessels; and it seems to have been found, in practice, to have been attended with other objections, for it has been gradually relinquished by the government vessels, and is now, we believe, quite discontinued.

About the year 1833, Mr. Field, of the firm of Maudslay and Field, proposed the *split paddle*, which is now coming into very extensive use. In this wheel each paddle board is divided into two or more narrow slips arranged one behind the other, like the laths of a Venetian blind or the steps of a step-ladder. These wheels are as efficient in propelling when at the lowest point as the common paddle boards; and when they emerge, the water escapes simultaneously from each narrow board, and is not thrown up, as is the case with the common paddles.

The limit of the extent of the voyages capable of being made in one uninterrupted trip by a steam vessel will evidently depend on the efficiency of the fuel. As the means of economising this are improved, this limit will be more extended. In 1835, when it was first proposed to cross the Atlantic from Bristol to New York in a single trip, it was considered by persons who had given much attention to the subject that, in the state of steam navigation at that time, the expense would be so enormous, and the tonnage of the vessel so engrossed by the fuel, that the success of the project as a commercial speculation intended for permanent operation throughout all seasons of the year was more than doubtful. A long interval, however, elapsed before the experiment was brought into full operation; and, in the meanwhile, much improvement was effected in the application of the steam engine to navigation. The experiment has been happily at length brought into full practical effect by two companies. What the commercial result has been to the speculators, we are not able to say.

At the time referred to in 1835, those who were doubtful of the expediency of attempting the passage to New York recommended a trial of a line to Boston, touching at Halifax. This has since been accordingly effected, with every prospect of permanent success.

Steam Navigation in America. — The problem of the application of steam power to water transport presented itself in the United States under conditions very different from those under which it offered itself in Europe, and its solution has been accordingly productive of very different results. While the chief object of the commercial interests in Europe was the establishment of lines of steam vessels connecting the great cities and coast towns of the British dominions with each other, and with those of the Continent, and, as the art advanced, to extend the same social and commercial benefit to the coasts of the chief countries of Europe, so as to stimulate the social intercourse of nations too long disunited and struggling in unprofitable warfare, and thereby to diffuse equally among all the benefits of general commercial intercourse, America, standing alone in her vast extent of territory, having no near neighbours with whom to cultivate social or commercial relations, regarding her immense country intersected by some of the most noble rivers in the world, enriched by the largest sheets of inland water which can be found upon the globe, — thus situated, she saw that *inland navigation*, river and lake transport, was the great application of steam by which her rising and enterprising population would be most benefitted, and by which the necessary intercourse could be maintained between her great western emporiums erected on the banks of the Mississippi and Ohio; her more northern settlements on the coasts of the gigantic lakes Ontario, Erie, Michigan, and others; and on the eastern rivers, the Hudson, the Delaware, and the Susquehanna. It was therefore to the construction of steam boats suitable to such internal navigation that American genius was directed; and in this it has been eminently successful.

The American river steamers are in general long narrow boats with a small draught of water, supporting a platform or deck of vast magnitude projecting on either side considerably beyond the limits of the boat on which it rests. The paddle wheels are large, and are usually impelled by a single engine placed with its boiler and machinery *above the deck*. The engines are almost universally non-condensing high-pressure engines, and many of them are worked expansively. The fuel is generally wood; but in many cases, especially in the eastern vessels, coal. In the structure of the machinery there is much rudeness and simplicity, and none of that extreme precision of construction and fine finish is to be found which is almost always observable in European vessels. Owing to the form of the boats and the smooth water in which they work, a much greater average speed has been attained than in the sea-going steamers of Europe. Although we have reason to know that in common reports the average rate of the American steamers has been grossly exaggerated, there is no doubt that their rate of going is very considerable. On the Hudson, between New York and Albany, are the fastest steamers in the United States; and it is probable that if the average speed of these vessels, taken in all circumstances of weather and tide, be stated at thirteen geographical miles an hour, it is not overrated.

The principal theatres of river steamers in the United States are the Hudson and the Mississippi, with its branches. The Hudson is navigated by steam from its mouth at New York to a distance of about 160 miles, the chief point of traffic being the city of Albany, situated on its western bank, at about 145 miles from New York. Although this extent is not considerable, the intercourse upon it is quite enormous during the seasons of the year in which the river is open. It is obstructed by the frost during the winter months.

The Mississippi is navigated by many hundred steamers of very large tonnage. This steam traffic is carried on through a distance of nearly 2000 miles from the mouth at New Orleans. The towns of Natchez, Cincinnati, Louisville, Juttsburgh, and numerous others, maintain, by this means, an easy and constant intercourse with the capital of the southern states.

The steamers on the Mississippi and the Ohio are constructed with even less attention to safe engineering principles than those of the western rivers, and, consequently, more frequent and fatal accidents arise from explosion and other causes.

The dimensions of the steamers which ply on the Hudson are generally as follows: — The length of deck from 150 to 250 feet; the breadth of beam from 20 to 30 feet; and the depth of the hold from 8 to 10 feet. They are generally, but not always, worked by a single engine; the length of stroke is never less than 8 feet, but the most common length is 10 feet; the diameter of the piston varies from 40 to 66 inches, and the diameter of the paddle wheels from 20 to 25 feet; the breadth, or rather the thickness of the wheel, varies from 12 to 14 feet, giving a great extent of surface to the paddle boards, which have usually a dip of 2½ feet; the draught of water of these boats varies from 6 to 9 feet; the steam is generally worked expansively, being cut off at half the stroke, and often sooner; the wheels are said to make, on an average, from 25 to 30 revolutions per minute.

The Ohio steamers are inferior in magnitude to those on the western waters; their number must be very considerable. About seven years since, the number plying

on the river and its branches was about 200; and that number has probably since been nearly doubled. "Economy," says Mr. Stevenson in his *Engineering Tour*, "would seem to be the only object which the constructors of these boats have in view; and therefore, with the exception of the finery which the cabins generally display, little care is expended in their construction, and much of the workmanship connected with them is of a most imperfect and insufficient kind. When the crews of these frail fabrics, therefore, engage in brisk competition with other vessels, and urge the machinery to the utmost extent of its power, it is not to be wondered at that their exertions are often suddenly terminated by the vessel taking fire and going to the bottom, or by an explosion of the steam boilers. Such accidents are frequently attended with an appalling loss of life, and are of so common occurrence that they generally excite little or no attention."

The steamers of the Mississippi vary in magnitude from 100 to 700 tons; and, unlike the light mould of the Hudson steamers, they are heavily built, so as to give them abundant tonnage for goods. They are built with a flat bottom, with a draught of from 6 to 8 feet of water. A deck is supported by the hull at about 5 feet above the level of the water, and the space in the hull under this deck is appropriated to the cargo. The whole of the steam machinery is placed on this deck; the engine standing in the middle of the vessel, and the boilers and furnaces towards the bow. That part of the lower deck towards the stern is occupied by the crew and deck passengers, and is generally a scene of great filth and squalor. From the front of the paddle boxes, a staircase leads to a gallery or balcony of about 3 feet in width, which surrounds a structure raised upon the deck, and extending nearly the whole length of the vessel, presenting the external appearance of a long wooden house, the doors and windows of which open on this balcony. This structure is, in fact, the great cabin, extending from the two smoke funnels to within about 30 feet of the stern; this latter space, extending quite to the stern, is appropriated to the ladies' cabin. The large cabin, which contains the gentlemen's berths, is also used as the chief dining room. From the balcony just mentioned staircases on either side lead to the third, or upper deck, 30 feet above the level of the water. The wheel house, in which the steersman is placed, is erected on the fore part of this deck, and the motion is communicated to the helm by ropes or iron rods.

The engines are constructed with very small cylinders, worked with steam of great pressure. The diameter of the cylinder is often under 18 inches, while the length of stroke is from 5 to 6 feet. The safety valve is usually loaded with 100 lbs. per square inch, which, at the discretion of the captain, is sometimes increased to 150 lbs. Some of the large boats on the Mississippi are equal in magnitude to those on the Hudson, having a length of 230 feet, and a breadth of beam of 28 feet. With this great magnitude of deck and a capacity of not less than 1000 tons, they do not draw above 8 feet of water. For further details respecting steam navigation in general, and in the United States, see *Dr. Lardner on the Steam Engine*, 7th edition; Appendix to *Tredgold on the Steam Engine*; and *Stevenson's Civil Engineering in North America*.

STEA'RIC ACID. (Gr. στεαρ, *fat*.) One of the acids produced in the process of saponification by the action of alkalies upon *stearine*.

STE'ARINE. (Gr. στεαρ.) That part of oils and fats which is solid at common temperatures.

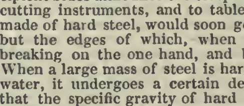
STE'ATITE. (Gr. στεαρ.) A soft mineral of an unctuous or soapy feel; hence called *soapstone*. It is a hydrated silicate of magnesia and alumina.

STEATO'MA. (Gr. στεαρ.) A tumour, the contents of which are of the appearance and consistency of hard fat.

STEEL. (Germ. stahl.) This most useful and curious substance is a compound of iron and carbon: their relative proportions vary in steel of different qualities; but in that used for ordinary purposes, the carbon rarely exceeds 2 per cent., and is generally below it. Certain kinds of iron are preferred to others in this manufacture; but this relates entirely to its purity, which is the essential requisite. Steel is made by a process called *cementation*, which consists in filling a proper furnace with alternate strata of bars of the purest malleable iron and powdered charcoal: atmospheric air is carefully excluded from the boxes containing the bars, and the whole kept for several days at a red heat. By this process carbon, probably in the state of vapour, penetrates, and combines in the above small relative proportion with the iron, the texture of which, originally fibrous, becomes *granular*, and its surface acquires a *blistered* character. The malleability of steel falls far short of that of iron; but it is harder, and more sonorous and elastic, and susceptible of a higher polish, and has less tendency to rust. At a red heat it admits of hammering into various forms, and of being *welded* or united by the blows of the hammer to another piece of steel or iron. Blistered steel, rolled or beaten down into bars, forms *shear steel*; and if melted, cast into ingots, and again rolled out into bars, it forms *cast steel*, which, when well prepared, has the great recommendation of perfect uniformity of texture, and a finer and closer grain. The peculiarity of steel, upon which its high value in the arts in great measure depends, is its property of becoming, by sudden quenching in water, when at a bright red heat, extremely *hard*, and of being again *softened* down to any requisite degree by the application of a certain temperature, which may be indicated by a thermometer, commencing at about 300°, and terminating at a dull red heat. This process is often called *tempering*; and the workman is sometimes guided in the extent to which it is carried by the *colour* of the polished surface of the heated steel, which is at first rendered of a pale straw tint, then yellow, brownish, purple, and blue, as the temperature rises from one extreme to the other. The latter colour indicates extreme softness and elasticity, such as belongs to watch springs, some sword blades, &c.; pale straw indicates great hardness, as for razor blades; yellow is somewhat softer, and shows a fit temper for penknives; and the incipient blues announce the temper that belongs to coarser cutting instruments, and to table knives, any of which, made of hard steel, would soon get spoiled and notched, but the edges of which, when duly tempered, resist breaking on the one hand, and bending on the other. When a large mass of steel is hardened by quenching in water, it undergoes a certain degree of expansion, so that the specific gravity of hard steel is somewhat less than that of soft. It has been attempted to improve the quality of steel for certain purposes by adding to it small portions of other metals: hence the term *silver steel*, &c.; but none of these alloys have on the whole proved superior to well-made common steel. There is a kind of steel imported from India, known under the name of *wootz*, the cutting instruments of which are celebrated for the toughness and durability of their edge. It appears probable that its peculiarities depend upon the presence of a little aluminum. When the surface of some kinds of steel is washed over with a weak acid, it acquires a peculiar mottled or *damasked* appearance, as if its texture consisted of an intimate mixture of two different kinds of steel, or of fine fibres of steel and iron. Steel, alloyed with a little nickel, often puts on this appearance; but these and some other imitations of the celebrated *Damascus* sword blades have not led to any important improvements in the manufacture of our cutting instruments. (See Stodart and Faraday, *Phil. Trans.* 1822.)

STEEL ENGRAVING. The art of engraving on steel. *See* ENGRAVING.

STEEL YARD. A balance by which the weights of bodies are determined by means of a single standard weight. The instrument, which is represented in the annexed figure, is a lever having unequal arms.



The load whose weight is to be determined is suspended from the extremity B of the short arm; and in weighing the constant weight or counterpoise P is slid along the longer arm until the equilibrium is established. Divisions traced on this arm indicate the weight at B corresponding to each position of P.

In the Roman steel yard, or *statera*, the lever was so constructed that the centre of gravity was brought immediately over the point of support; and the system being accordingly balanced upon its fulcrum F, the effect of the weight of the lever was neutralized. The longer arm was then divided into parts, each equal to the shorter arm, and those again equally subdivided. Suppose now the length of the shorter arm, or the distance F B, to be one inch, and the constant weight P to be one pound; then if P be placed at the distance of five inches from F, it will make equilibrium with a load of five pounds suspended from B; for, from the property of the lever, when the equilibrium is established the weight P is to the load at B as the distance of B from F is to the distance of P from F. Whatever proportion, therefore, F P has to F B, the same proportion has the weight suspended from B to the constant weight P.

The steel yard in common use is constructed somewhat differently, the beam being seldom made so as to balance itself on the fulcrum F; but the error that would arise on this account is compensated by beginning the divisions at that point where the weight P being placed the equilibrium is established. If, therefore, when P is removed the longer arm preponderates, the divisions commence from a point between F and B. For the purpose of increasing the range, there are also in general two fulcra, from either of which the beam may be suspended, and two corresponding scales of division are marked on opposite sides of the longer arm.

For weighing heavy loads the steel yard is a convenient instrument; but for smaller weights it is susceptible of less accuracy than the common balance. It should be con-

structed so that the point of support F, and the point of suspension at B, may be in the same straight line with the divisions of the beam.

STEEL YARD, MERCHANTS OF THE. A company of London merchants to whom the *steel yard* (see above) was assigned by Henry III. A. D. 1232. They were all foreigners, chiefly Flemish and German, and were long the only exporters of the staple commodities of England.

STEENING, or STEANING. In Architecture, the brick or stone wall or lining of a well.

STEEPLE. In Architecture, a tower of various forms, usually attached to churches and other public buildings, in which bells are frequently but not always suspended.

STEER. To keep the ship on a given direction. This is done by moving the rudder by the tiller, which last is moved from that side to which the ship's head is required to be moved.

STEERAGE. The steering of the ship. Also a place below in the fore part of ships, as distinguished from the *chief cabin*; but the term is of uncertain acceptation.

STEGANO'GRAPHY. (Gr. στεγανος, *covered*, and γραφω, *I write*.) The art of writing in cypher. *See* CYPHER.

STE'GANOPODS. (Gr. στεγανος, *covered*, πους, *a foot*.) The name of a family of swimming birds (*Natatores*) in the system of Illiger, including those species in which all the four toes are connected by the same web. It corresponds with the genus *Pelecanus* of Linnæus.

STEINHEILITE. A mineral of a blue colour; a variety of *iolite*.

STE'LA. (Gr. στηλη, from ἵστημι, *I stand*.) In Architecture, a small column without base or capital, usually with an inscription to record an event, or to perpetuate the memory of some deceased person. The ancients also used them for marking distances. There are several specimens of stelæ in the British Museum.

STELLA'TÆ. In Botany, a natural order of Exogens, also known under the name of *Galiaceæ*; which see.

STELLE'RIDANS, *Stelleridæ*. (Lat. stella, *a star*.) Star fishes. The name of the family of Echinoderms of which the genus *Asterias* is the type.

STE'LLIONATE. In the Roman law, a general term comprehending all sorts of fraud committed in matters of agreement which were not designated by any more special appellation. The name is said to be derived from *stellio*, a lizard, because the fraudulent man is comparable to that animal for versatility and address. The six common species of stellionate enumerated by Roman writers were, 1. When one sells the same thing to two purchasers; 2. When a debtor pledges to his creditors something which does not belong to him; 3. When one abstracts or damnifies something which he has pledged to creditors; 4. Collusion by two parties to the prejudice of a third; 5. When a vendor substitutes an object of less value for that which he has engaged to sell; 6. A wilful false declaration in an instrument.

STEM. In Music, the upright or downright line added to the head of a musical note; the head being that part filled in black or left open, as the case may be.

STENELY'TRANS, *Stenelytra*. (Gr. στενος, *narrow*; ελυτρον, *a sheath*.) The name given by Latreille to a family of Coleopterous insects, comprehending those in which the elytra become narrow at the posterior part of the body.

STENO'GRAPHY. (Gr. στενος, and γραφω, *I write*.) The art of short-hand, otherwise termed *tachygraphy*. This art has been practised from remote antiquity, and is said to have originated in the hieroglyphics of the Egyptians. Numerous systems of stenography have been invented in more recent times, many of them of great simplicity; but it would be out of place here to enter into any details respecting them.

STEP. A block of wood, or in large ships of late years a strong solid platform, upon the kelson, supporting the keel of the mast. It was found that the weight of the mast, yards, &c., added to the enormous force upon the rigging, especially during strong winds, forced the keel down.

STEPPES. (Russ.) The name given to the vast system of plains peculiar to Asia; synonymous with the prairies of North America and the Ilhanos of South America. The steppes of Russia are not unlike the heaths of Germany, being in part susceptible of cultivation, and affording pasturage for numerous herds of nomadic tribes.

STERCO'RIANISM. In Ecclesiastical History, a nickname which seems to have been applied in the Western church, in the 5th and 6th century, to those who held the opinion that a change took place in the substance of the consecrated elements, so as to render the divine body subject to the act of digestion. (See *Mosheim*, vol. ii. transl. 1790, p. 342.)

STERELMI'NTHANS, *Sterelmintha*. (Gr. στερεος, *solid*, and ελμινς, *an intestinal worm*.) The name of a class of internal parasitic animals or Entozoons, comprising those which are composed of a solid parenchymatous substance, in which the nutrient and generative canals are simply excavated, and not freely suspended in an abdominal cavity.

STEREOGRA'PHIC PROJECTION. (Gr. στερεος, *solid*; γραφη, *description*.) The projection of the sphere upon the plane of one of its great circles, the eye being situated at the pole of that circle. *See* PROJECTION.

STEREO'GRAPHY. In the Descriptive Geometry, the representation of solids on a plane.

STEREO'METER. (Gr. στερεος, *solid*, μετρον, *measure*.) In Hydrodynamics, an instrument invented by M. Say, a French officer of engineers, for determining the specific gravity of liquid bodies, porous bodies, and powders, as well as of solids. The instrument may be described as follows: — Let A E be a glass tube, about three feet long, and open at both ends, the upper part A B being about 4-10ths, and the lower 2-10ths of an inch in diameter. The upper edge is ground smooth, so that it can be shut air-tight by a piece of ground plate glass; and the upper part A B communicates with the lower by a very narrow slit at B, which allows air to pass, but prevents the passage of sand or water. In using the instrument, a powder (for instance) is placed in the tube A B, and the lower part B E is plunged into a vessel containing mercury till the fluid rises exactly to B. The ground glass cover is then placed upon the mouth A, and there is now no air in the tube except what is mixed with the powder. Supposing the barometric pressure to be 30 inches; let the tube be elevated until the mercury stands within it at a point C, 15 inches above its surface in the open vessel, and it is manifest that the air within the tube is pressed with exactly half an atmosphere. It consequently expands to twice its original bulk, and hence the tube A B now contains only half the quantity of air it contained at first. The part B C must therefore contain the other half, or the air in B C is equal to the air mixed with the powder in A B; and being half the original quantity under half the original pressure, it fills the same space which the whole occupied previous to the expansion. Let the powder be now removed from A B, and the process repeated when the tube is filled with air. The quantity of air being now greater, will, when expanded to twice its bulk, fill a larger space than B C, and the mercury will rise only to some point D; but as the expanded air occupies exactly the same space in B D or B C as the whole occupied in A B under twice the pressure, it follows that the cavity C D = B D — B C is equal to the bulk of the solid matter in the powder. If, therefore, we now find the number of grains of water which would fill the part C D, we determine the weight of water equal in bulk to the solid matter in the powder; and by comparing this with the weight of the powder, we obtain its specific gravity. (*Ency. Brit.* art. "Hydrodynamics.")

Say's stereometer was first described in the *Annales de Chimie* for 1797. An instrument on exactly the same principle was afterwards brought forward by Sir John Leslie under the name of a *coniometer*.

STE'REOTYPE. (Gr. στερεος, *solid*, and τυπος, *a figure*.) Masses of letters, called letter-press plates, of the size of a page, cast from a plaster mould, in which an exact representation of the types has been made, and thus forming the permanent plates from which books are afterwards printed. As the art of printing (*see* PRINTING) began with the impression of whole blocks, it may be said that in its progress towards perfection it has again reached the same point by the introduction of stereotype plates. The origin of the more modern invention is involved in greater obscurity than might at first sight appear probable from its comparatively recent date. By some writers the merit of the invention is ascribed to the Dutch, who had adopted the plan of printing with solid or fixed types in the 17th century; but it was not till the end of the last, and the commencement of the present century, that the process was perfected and generally introduced. In this useful invention, the most prominent names are Ged of Edinburgh, Tulloch and Foulis of Glasgow, Didot in Paris, and Wilson and Earl Stanhope in London. The process of stereotyping is very simple. A page of any work proposed to be stereotyped is set up with moveable types in the ordinary way. A plaster cast is then taken from it, which, being first dried, is immersed in fluid metal. The cast or plate, after being sufficiently cooled, is then withdrawn from the mould, and, at a subsequent stage, carefully examined with a view to removing any imperfections previous to its being printed from. The plaster used for forming the mould is pulverised gypsum, mixed with water to the consistence of cream. After the form of types has been surrounded with a brass frame, and slightly oiled on the surface, the fluid plaster is poured upon it, and, by the application of a brush, made to fill every cavity of the letters, the superfluous portion being scraped off. When the plaster has set sufficiently hard, it is by means of the frame lifted off the face of the type and detached from it. It is then

baked to dryness in an oven; and when quite hot it is placed in an iron box, or casting pot, which has also been heated in an oven. The box is now plunged into a large pot of melted type metal, and kept about ten minutes under the surface, in order that the weight of the metal may force it into all the finer parts of the letters. The whole is then cooled; the mould is broken and washed off; and the back of the plate turned smooth on a lathe, or planed by a machine. (*Conversations-Lexicon.*)

STE'RLING. The legal description of the English current coin, of which the most probable derivation is from *Easterling*, the popular name of the Baltic and German traders who visited London in the middle ages; but in what manner it came to be so applied is unknown. Camden says from the employment of German artists in coining. The silver penny was first called Esterling.

STERN. In Naval affairs, the after extremity of a vessel.

STE'RNA. A genus of web-footed birds, having a bill as long as or longer than the head, almost straight, compressed, and pointed; the mandibles of equal length, the upper one slightly inclined towards the point; nostrils pierced towards the middle of the bill; legs small, naked to above the knee; three anterior toes, united by an indented web; the hind toe free; wings very long and pointed; tail more or less forked. From the two latter characters, the species of *Sterna* are sometimes called "sea swallows:" their proper English name is "tern."

STERNO'XI. (Gr. στερνος, *sternum*, and οξυς, *pointed.*) The name of a tribe of Coleopterous insects, comprehending those in which the sternum is prolonged into a point at both extremities.

STE'RNUM. (Lat. sternum, *the breast bone.*) In Comparative Anatomy, the simple or compound bone which completes the thoracic cage anteriorly, and serves as a medium of union to a greater or less number of the ribs. The sternum is not present in the skeleton of Fishes, Amphibians, or Ophidians. In Saurians, the anterior portion is generally expanded, to be joined to the broad coracoids and clavicles. In Chelonians, this part of the skeleton is remarkably developed, and very complex, and constitutes the greater part of the plastron or floor of their defensive osseous case. In Birds, also, it is more or less complex at the beginning of its development; but the different ossifications are soon blended together, and form a single broad bone, principally remarkable for the keel-like process developed from the middle line of its under surface. This keel is subservient to the attachment of the muscles of the wing, and bears a direct proportion to the powers of flight; except where the wings, as in the penguin, are used as fins. In the Struthious birds, the keel of the sternum is wanting.

In Mammalia, the sternum is generally simple, and consists of a single chain of ossicles; except in the orang-utang, and occasionally in man, where a double series of ossifications are originally developed in the body of the bone, but which afterwards become confluent. The upper portion, or *manubrium sterni*, remains long distinct from the main body of the sternum; in man, the cartilaginous appendage of the lower edge of the sternum is called xiphoid or ensiform.

STE'THOSCOPE. (Gr. στηθος, *the chest*, and σκοπεω, *I explore.*) A cylinder of cedar wood, about 12 inches long, and 1 in diameter; perforated throughout its length, and divided into two parts for the convenience of using the whole or half its length. The end of each part terminates in a funnel-shaped cavity. Its use is adverted to under the head AUSCULTATION.

STEWARD, LORD HIGH, was anciently the first officer of the crown in England, with the Latin title of Magnus Seneschallus. The office was at one period annexed to the lordship of Hinkley, in Leicestershire, held by the family of De Montfort; but on the rebellion and fall of that noble house, it was in effect abolished as a permanent dignity, and is now only revived *pro hâc vice* on the occasion of a coronation, or the trial of a peer. In the former case, the lord high steward's commission is to settle matters of precedence, &c.; in the latter, to preside in the House of Lords.

STEWARD, LORD, OF THE HOUSEHOLD. An officer of the king's household in England; in Norman French, Seneschal. He is steward of the marshalsea or court of the household; an office which he performs by deputy. In his department is the counting house where the expenses of the king's household are taken; within which is the board of green cloth, an ancient court which has jurisdiction of offences committed within the king's palaces and verge of the court.

STHE'NIC DISEASES. Those which are the result of inflammatory or increased action; as opposed to asthenic, or diseases of debility.

STIBIUM. Antimony.

STI'CHOMANCY. (Gr. στίχος, *a line*, and μάντεια, *prophecy.*) Divination by lines or passages in books taken at hazard. Among the Romans, verses from the Sibylline books were written on slips of paper, which were thrown into a vessel; and future events were conjectured from the interpretation of one of these slips drawn out at hazard. Of the same kind were the *Sortes Virgilianæ, Homericæ*, &c.; a sort of literary superstition by which the works of authors were consulted, and the meaning of a line casually taken assumed as indicative of the fate of the person discovering it. Verses of the Bible selected in this way by chance have been, and are still, frequently taken by the superstitious as oracular. This sort of divination has been called *bibliomancy*, or *sortes biblicæ*. It was condemned by the council of Vannes in 465, and other early synods; but was long afterwards practised in France at the elections of bishops, abbots, &c. The custom of drawing by lots verses from the Bible on such occasions is said to have prevailed as late as 1740, in the cathedrals of Ypres, St. Omer, and Boulogne. *See* SORTES, SORTILEGE.

STICK, GOLD. The colonels of the two regiments of Life Guards are so called, whose duty it is to be in immediate attendance on the sovereign on all state occasions. These colonels do duty for a month alternately; the one on duty being called the *gold stick in waiting*. The field officer of the Life Guards, when on duty, is called *silver stick*. The term originated in the custom of the sovereign presenting the colonel of the Life Guards with a gold stick on his receiving the regiment.

STI'GMA. (Gr. στιγμα.) An impression such as that made by branding with an hot iron. Stigmatizing was a common practice among the ancients to mark their slaves as property; and it is pursued at the present day among slave-drivers. It was customary also to stigmatize the votaries of some of the gods with some recognized emblem of their divinity, such as the ivy of Bacchus, trident of Neptune, &c.; or with the initial of their names, or some mystical number. It is supposed that reference is made to this practice by St. John, Rev. ch. 13. *See* TATTOOING.

STIGMA. In Botany, the upper extremity of the style without a cuticle, in consequence of which it has almost uniformly a humid and papillose surface. It is the part upon which the pollen falls, and where it is stimulated into the production of the pollen tubes, which are indispensable to the act of impregnation.

STI'GMATA. In Theological language, the marks of the wounds of our Saviour. The text at the end of the Epistle to the Galatians, "From hence let no man trouble me, for I bear in my body the marks of the Lord Jesus," seems to have given rise to the superstitions promulgated in the Roman Catholic church respecting the impression of the stigmata on favoured saints; of which the legend of St. Francis of Assisi affords the most remarkable instance.

STILE. In Architecture, the vertical piece in framing or panelling. *See* RAIL.

STILL. (Lat. stillare, *to drop.*) An apparatus for the distillation of liquids upon the large scale. It includes the *body*, or *boiler*, which is usually set in brick-work over a furnace, and to which is annexed the *head*, forming the communication between the boiler and *condenser* or *worm pipe*; from the extremity of which the distilled liquid passes in successive drops, or a small continuous stream, into the *recipient*. There are an infinite variety of stills adapted to particular purposes, of which the most important are the distillation of spirituous liquors. (See *Ure's Dict. of Arts, &c.*)

STILT BIRD. The name of the *Himantopus melanopterus*, significative of its very long and slender legs.

STI'NKSTONE. A bituminous carbonate of lime, which exhales a fetid odour when rubbed.

STINT. In Coal Mines, a measure of work used under ground, 2 yards long and 1 broad, which each miner clears before he removes to another place, and which is proved by a boy appointed for the purpose, who is colloquially called "the judge."

STIPEND (Lat. stipendium), signified originally the pay of soldiers. In a legal sense it is applied to the salary or allowance given to some person for transacting the business of another; but in Scotland the term is almost exclusively confined to the provision made by law for the established clergy. *See* PRESBYTERY.

STI'PPLING. In Engraving, the method of producing shadows by means of dots of greater or less size, according to the intensity of shadow required. By this method the resemblance to chalk drawings is produced.

STI'PULA. In Botany, a small appendage situated upon each side of the base of a petiole, most commonly of a less firm texture than the latter, and having a subulate termination: the word is also used in describing *Hepaticæ*, to denote the appendages which are occasionally present at the bases of the leaves, but of which they seem rather to be lobes than distinct organs.

STOCK DOVE. The name of the wild species called *Columba Œnas* by Linnæus.

STOCK EXCHANGE. The name given to the system whereby the purchase, sale, and "carrying over"

of stock and shares are effected by certain parties called brokers. This curious and complicated subject may be explained and discussed under three different heads: — viz. first, the parties engaged in stock transactions, whether brokers or jobbers; secondly, money and time bargains; thirdly, the rules and regulations by which these operations are conducted.

The Clearing-house in Lombard Street affords the greatest facilities to the transactions of the Stock Exchange, inasmuch as, without its intervention, difficulties and embarrassments would present themselves in the final settlement or adjustment of those transactions of an almost insurmountable character. By means of this clearing-house, all the great monetary transactions of the day are brought to a close by 5 o'clock in the afternoon; whereas in the ordinary mode of paying or receiving money, whether in notes or hard cash, their settlement might not be finally effected for several days afterwards, to say nothing of the security afforded to all parties concerned by the operation of the clearing-house.

The members of the Stock Exchange are divided into two distinct classes: — viz. the brokers, and the jobbers. It is the business of the brokers to receive and to execute the orders of merchants, bankers, capitalists, and private individuals, who are "out of the house;" the Stock Exchange being amongst its own members honoured with that dignified appellation!

The jobbers remain stationary in the "house," and ready to act upon the orders thus received by the brokers. And here it may be as well to explain the nature and character of the business transacted by these jobbers, who, being men possessed of more or less capital, endeavour to turn it to account in the manner we are about to explain. It is their business to be always prepared to make a price to the brokers whenever the latter present themselves: the readiness which they display in offering to do business to large amounts at the apparently small difference of 1-8th per cent. would appear extraordinary, were it not that they are so numerous that an eager competition is excited amongst them for the favours of the brokers. When one of the latter appears in the market, he is surrounded by a knot of jobbers, who announce themselves ready to buy or sell whatever amount of stock he has to deal in at a price varying only 1-8th per cent. For instance, if a broker has to do business in 5000*l*. Consols (the market price being about 90), the jobber offers to buy his 5000*l*. at 90, or to sell him that amount at 90⅛, without being in the slightest degree aware whether the orders of the broker are to buy or to sell, and thus taking upon himself the risk of selling that which he does not possess, or of buying what he does not intend to keep; his only object being to undo his bargain, at a difference of 1-8th per cent., or even less, with another broker, who may have to effect an operation the very reverse of the other, which 1-8th or even 1-16th constitutes his profit.

Without the intervention of the jobber, therefore, it will be seen that there would exist a vast difficulty in effecting the transactions which daily take place. The jobbers are, in fact, the "middle men," who stand in the house in the character of dealers, always ready to buy or sell, thus obviating the necessity of the broker's going in quest of a second broker, with whom he might transact his business; or, in other words, whom it might suit to buy what the other broker had to sell, or *vice versâ*. Again, even if one were at hand, he might not be able to concur in the actual amount of stock which the other wished to deal in; whereas the jobber is ready to do business to any amount, even to the smallest fraction, and hence a great deal of time is saved. It often happens that a broker who has to dispose of shares not currently dealt in is frequently obliged to wait for months before he can find a purchaser; whereas, in the case of stock, the jobbers offer themselves as buyers or sellers at a moment's notice, and thus offer facilities for transactions in the public funds which could not be effected without them.

Having thus endeavoured to explain the difference between broker and jobber, and confined our attention hitherto to money transactions, we next proceed to describe the nature of "time bargains," which form so essential a feature in stock business. Indeed, the very existence of the Stock Exchange, as at present constituted, depends upon speculations in time bargains; for where there exists a body of 600 members, the actual *bonâ fide* business would not be sufficient to provide employment for them all, notwithstanding the magnitude of the national debt. Time bargains consist of purchases and sales of stock made for a certain fixed period, regulated by the committee. There can be little doubt that they had their origin in the business which has always been transacted in the funds during the periods when the stocks are shut. For instance, Consols usually close about the beginning of June and December; that is to say, the transfer books at the bank are shut for the space of five or six weeks, in order to afford time for the preparation of the dividend warrants, which are paid in the following July and January. Hence it is clear that a person wishing to buy or sell that particular stock during the period referred to would be unable to effect his object; but in order to secure the price of the day, he buys or sells the stock "for the opening," that is, for actual transfer on the day on which the transfer-books are reopened. This mode of doing business is legitimate enough; but this practice has no doubt given rise to operations of the greatest magnitude, founded, not on actual necessities, but merely on speculation; and this method being found convenient for one period, has been continued on other occasions, without, however, possessing the same pretext for its adoption. Periodical dates have consequently been fixed upon by the committee, similar to the "opening," at intervals of about six weeks, making altogether about eight "settling days," as they are called, in the course of a year. On these settling days are arranged and adjusted all the bargains made during the preceding six weeks for that particular day; those who sold stock having to deliver it on the one hand, and those who purchased having to accept and pay for it on the other. But as the majority of the speculators have no intention of doing either the one or the other, their bargains having been of a purely speculative character, founded on their anticipations of a rise or fall in the value of the securities, so whatever difference may exist between the price at which a party commenced his speculation and that at which he finally closed it is settled on this important day; and his operations most likely not having been confined to the same jobbers, but having been effected with several, it becomes necessary to balance them with the parties concerned, and much the same process takes place on this occasion as that practised at the bankers' clearing-house, by establishing balances between each other. Whatever balance remains unsettled is adjusted by the name of the *bonâ fide* purchaser of the stock (who intends to pay for it) being passed from one broker, or jobber, or speculator to another, until it comes into the hands of the party who intends to deliver or transfer the stock; by which means all the intermediate persons through whose hands it passes (the price given by the purchaser being marked on the ticket) are enabled to close their accounts with each other at that particular price, and to pay and receive the differences accordingly. In short, all transactions kept open until the settling day *must* then be closed; and the party who delays this operation until the last moment is often exposed to a loss, from the difficulty of finding others who, having adjusted their own accounts, are unable or unwilling to enter into a fresh transaction on this "day of reckoning," whereby he is compelled to pay something extra in the price to those who have it in their power to afford him this facility, in order to enable him to settle his account.

But, as many of the bargains made for this particular day are really *bonâ fide* transactions, the stock bought and sold being, in point of fact, delivered by the actual holder and taken by the new purchaser, let us briefly explain how this is effected. This process is one of daily occurrence, and is not necessarily confined to a settling day, although on such occasions it usually amounts to a considerable item, from its having extended over a wider period. In either case, however, the following is the way in which the matter is settled between the broker and his principal who has sold stock: — The broker usually passes his check for the proceeds of the sale to his principal, taking the precaution of crossing it, *i. e.* writing a banker's name across the check. When, however, Bank of England notes are demanded in lieu of crossed checks (as is sometimes the case), the bargain is made accordingly: in this case, the jobber who buys the stock provides them either by borrowing of those who happen to have large balances at their bankers', or from their own private bankers. The notes so borrowed by the jobber are then paid over to the broker, and by him to his principal. This operation is, however, seldom resorted to by men of business where there is no reason to doubt the credit of the party drawing the check.

The jobber, on the other hand, having sold the stock to some other broker, who buys for his principal, receives in return his check; so that, by this simple process of passing four checks, — viz. that of the purchaser to his broker, that of the broker to the jobber, that of the jobber again to the broker who first sold the stock, and that of the latter to his principal, — the whole transaction is completed.

To advert to another technical peculiarity appertaining to the Stock Exchange which may appear puzzling to the reader; the use, namely, of the terms "bull" and "bear." A *bull* is one who speculates for a rise; whereas a *bear*, on the contrary, is he who speculates for a fall. The "bull" would, for instance, buy 100,000*l*. Consols for the settling day, or, as it is technically termed, "for the account," with the object of selling them again during the intervening period at a higher price. The "bear," on the other hand, would sell the 100,000*l*. stock (which, however, he does

not possess) "for the account," with a view of buying them in for the purpose of balancing the transaction at a lower price than he originally sold them at. In stirring periods, when fluctuations of 4 or 5 per cent. often occur during "one account," vast profits may be realized, or equal losses sustained, by these gambling operations.

The transactions in the foreign market are carried on much in the same way as in that of the English stocks, with the exception that the settling days are much more frequent, occurring, as they do, once in every fortnight. The foreign "house" is quite of modern origin; but it is subject to the same rules and regulations as the English, with a few exceptions. The dealings are there carried on in all the foreign stocks, as well as in railway, mining, and other shares. The jobbers are distinct from those in the English house, although there is nothing to prevent them from dealing in both, if they possess sufficient intelligence to enable them to give their attention in two places at once.

In connection with time bargains may be noticed that important branch of business which goes under the denomination of "continuation," or "carrying over." This is nothing more than interest for money borrowed or lent on security of stock. The rate of this continuation or interest varies according to the abundance or scarcity of money, and the nature of the security offered. For instance, on British stocks, even when money is very scarce, it seldom exceeds the rate of 5 per cent. per annum from one account to another; whereas in the foreign market, where the security consists of foreign bonds of various and doubtful descriptions, it ranges from 5 to 10 per cent., or even more on particular occasions, when it reaches 15 per cent. per annum.

There are several causes which tend to produce this extraordinary variation in the rates of continuation; for in the case of Consols, which constitute the only stock for speculation in time bargains in the English market, the price varies so little in comparison with the value of the stock, in the course of an "account," that the security is considered good in itself; and therefore no extra charge is superadded by the party who lends his money. This is not the case with regard to foreign stocks, which are constantly fluctuating in value, a fact to be accounted for by the extremely precarious nature of this description of property. Most of the bonds in circulation in the foreign house have ceased to bear any interest whatever, and many of them bear upon them the marks of their shame and disgrace, in the shape of the arrears of interest, called *coupons*, overdue for several years. It is not, therefore, to be wondered at that foreign securities of this description do not command the same credit as our own English stocks; and it must hence follow, as a matter of course, that parties who wish to raise money upon them must consent to pay a higher rate of interest for the accommodation.

A great deal of business is transacted in this way; and some brokers, who possess the means of obtaining large sums of money without much difficulty, devote their entire attention to it. The process by which the operation is effected is simple, both in the English and foreign market. The present rate of continuation in the Consol market is 9-16ths per cent. until the opening; and if a person, we will suppose, wishes to lend money on that stock, from the shutting (on the 2d of December) to the opening (on the 14th of January, 1842), his broker procures him 1,000*l.* Consols as security, for which he furnishes the money at the actual price of the day, which is 90, making 900*l.*, and resells at the same time the said 1000*l.* stock for the opening (on the 14th of January) at $90\frac{9}{16}$, making 906*l.* 12*s.* 5*d.*, and thereby leaving a difference in his favour of 5*l.* 12*s.* 6*d.* for the loan of 900*l.* during the above period of forty-four days, which will be found to be at the rate of 5*l.* 3*s.* 8*d.* per cent. per annum. On foreign securities the principle is the same. Supposing he lends on the security of Spanish bonds, he receives as security 5100*l.*, for which he pays on the 30th of November, at the price of $24\frac{1}{2}$ per cent., 1249*l.* 10*s.*; but sells it to the same party for the 15th of December (the next settling day) at $24\frac{9}{16}$, producing 1252*l.* 13*s.* 9*d.*, leaving a difference in his favour of 3*l.* 3*s.* 9*d.*, or 1-16th upon the stock bought and resold, which, for fifteen days, is equal to 1-8th per cent. per month, or 12-8ths per cent. per annum, equal to 76*l.* 10*s.*, being at the rate of about 6*l.* 2*s.* 6*d.* per cent. per annum interest. This calculation is made upon the current rate of interest for the "continuation" of that stock on the 30th of November, which was considered as extremely low.

The continuation on shares, in which a great deal of business is also done, varies but little from the above; but a difficulty here arises, which offers a great obstacle to the lending of money for short periods.

The *stamps* which by law are necessary for the due transfer of property of this description, and without which transfer there could be no security to the lender of money, are so onerous, and press so heavily on all *bonâ fide* transactions, that notwithstanding the many attempts made at various times to evade them, they operate materially against the parties who lend money upon them, and, in fact, neutralize all profit for short periods.

Persons who have sold shares or stock, if they are not in immediate want of their money, frequently avail themselves of this method of "continuation," in order to obtain interest for it until they actually deliver the stock. On the other hand, speculators for the rise are by this means able to carry over their purchases from one account to another; and although it may appear strange that they should be paying at the rate of 5 and even 10 per cent. per annum interest on a stock which, in the instance of Consols, pays them only 3 per cent., and in that of Spanish pays them actually nothing, still, when viewed solely in the light of speculations, the rise in either security, if it take place, will more than compensate for this apparent inconsistency.

The proceedings of the Stock Exchange are regulated by a committee consisting of thirty members, who are elected from the general body every Lady-day, each member having one vote. They take care that the rules and regulations enacted for the admission and expulsion of members, and for the settlement of disputes, are properly observed; and although some of their laws are at variance with the established laws of the country, they are not so strictly enforced by the committee as to bring them into collision with the courts of justice: they fully answer the purpose for which they were intended, and all members previously to their admission subscribe to the conditions there laid down.

All members, on being admitted, are obliged to produce three securities of 300*l.* each for the first two years of their probation, which 900*l.* becomes forfeited in the event of their failure, and goes to the creditors of the new member. In consequence of their being interdicted from engaging in any other business, on becoming members of the Stock Exchange they are no longer subject to the bankrupt laws; and therefore, in the event of failure, all their assets are secured to the creditors *in* the house, to the exclusion of those *out* of it. This rule is enforced in order to secure the house from the loss which would ensue to its members, were the legal creditors (if any existed) to step in and lay claim to their property.

The tendency of the above regulation is to insure honesty amongst its members. Should any principal have reason to complain, he has only to appeal to the committee, who instantly take cognizance of the matter, and subject it to the strictest investigation. Defaulters whose conduct has been dishonourable are punished, and an example is made of them by publicly affixing their names in the house on what is termed the *black board:* this is the heaviest disgrace which a member can possibly experience. (For this elaborate account of the procedure of business in the Stock Exchange, we are indebted to the *Times* of 1841.)

STOCKS. A well-known kind of punishment. The practice of confining men by the legs was so common as to have given the ordinary name to a chain of any kind in several languages: *e.g.* Gr. πέδη, Lat. compes, Engl. fetter; all from πούς, *foot*. The stocks in England have been, generally speaking, rather used for restraint than punishment, constables being empowered to put disorderly persons into them; but it is likewise ordered by some statutes as a punishment on conviction. It is now almost disused; though, we believe, not entirely in remote districts.

STO'ICS. A celebrated sect of antiquity; so called from the *stoa* or *porch* in Athens, which was the scene of the discourses of their founder Zeno of Cittium (B.C. 300). The Stoics are proverbially known for the sternness and austerity of their ethical doctrines, and for the influence which their tenets exercised over some of the noblest spirits of antiquity. To give a connected and systematic account of the philosophical principles on which they grounded their moral precepts is a less easy task than, from the notoriety of the latter in some of their main features, might have been anticipated. Their speculations were not confined to ethical subjects, but aimed at embracing the whole circle of human knowledge; physics, theology, and logic, no less than morals and politics. Their system, as far as we can gather from the notices preserved by Cicero, Diogenes, and others, appears to be an attempt to reconcile a theological pantheism and a materialist psychology with a logic which seeks the foundations of knowledge in sensible experience, and a morality which claims as its first principle the absolute freedom of the human will. Of the mode in which they combined dogmas apparently so inconsistent into a philosophical whole, we have accounts sufficient to inspire us with respect for the earnestness and strength of character possessed by the leaders of their sect, and with admiration of their subtlety, ingenuity, and depth. We discern, at the same time, in all their speculations, equally a narrow and controversial spirit, most unlike the critical but comprehensive impartiality which marks the philosophical writings of their great predecessors; of Plato, and, in a still more eminent degree, of Aristotle. The

philosophy of the Stoics was essentially polemical. On every side it presented an armed front to an opponent. It sought to confute the academic scepticism by the strenuous assertion of the truth of sensible perceptions, and the validity of the judgments to which they lead by a vigorous protest in favour of the common sense of mankind as opposed to the theories of the schools. Sensation, they affirmed, is not merely a passive affection of the mind; it becomes, under certain conditions, perception or *comprehension* (κατάληψις), — a faculty whereby the mind reaches beyond itself, and *lays hold*, as it were, on outward being. From the acquisitions of sensible experience are formed conceptions and judgments of successive stages of generality, which it is the province of the reason to construct into philosophical system. Such is the stoical logic, which is consequently a *material*, and not, as with Aristotle, a *formal* science. An equally controversial bearing is perceptible in the remainder of their philosophy. Their greatest enemies, the Epicureans, had adopted the *mechanico-corpuscular* theory of Democritus, which accounted for all physical phenomena by the varieties in size and figure of the ultimate atoms of which all substances are the aggregate. The fortuitous concretions which thus became the first cause of all things, had attracted the partialities and won the assent of a sect averse in all things equally to limitation or constraint. The Stoics espoused the opposite doctrine of a one all-pervading substance, a permeating ether, a creative fire, the source of life and law to the material universe. On this they built their doctrine of a universal providence, excluding chance in the least things as in the greatest, and directing all events by irresistible necessity to the promotion of perfect good. The same hypothesis furnished them with a ground for the first principle of their ethical doctrines. "Live according to nature" is, with the Stoics, the expression of the coincidence which ought to exist between the human will and the universal reason, which, as we have seen, they identified with the life and power of nature. This coincidence is virtue, the only good; as vice, its opposite, is the only evil. All things else are in themselves indifferent; being approved or disapproved only by comparison. Virtue is the perfect harmony of the soul with itself; vice is, in its essence, inconsistent and self-contradictory. The wise man, the ideal of human perfection, is absolutely, and without qualification, free. His actions are determined by his free will. with a power as irresistible as that by which universal nature is guided and animated. In the one no less than in the other, freedom and necessity are one.

In these doctrines the controversial character to which we have adverted is sufficiently obvious. Much, however, that is exaggerated and paradoxical, both in the tenets of the Stoics and in those of their opponent Epicurus, is to be accounted for by a reference to the political circumstances of the age in which both lived. The pressure of public calamity and the utter extinction of national life in Greece, while they precluded all healthful exercise of the duties of a citizen, — duties which had entered so largely into the calculation of the earlier Greek moralists, — would drive the more virtuous and thoughtful part of mankind to seek in the development of the individual life for that satisfaction which they sought elsewhere in vain. It is easy to conceive that the same circumstances which would recommend to minds of a certain order the good-humoured apathy and the tranquil voluptuousness of the garden, might, with men of sterner temperament. be the occasion of drawing forth all the energies of their will. and of placing those energies at once in distincter consciousness to themselves, and in sharper antagonism with the evil that surrounded them. In the declining period of the republic, as well as in the darkest periods of the empire, we find the noblest Romans seeking for consolation in the doctrines of one or the other of these rival sects. Brutus, Seneca, Epictetus, and the philosophic emperor Aurelius, are among the names of the most celebrated Roman Stoics. Little, however, was done by the Romans to advance the speculative part of the stoical philosophy, which was indebted for its systematic form to Cleanthes and Chrysippus.

The chief sources of information concerning the doctrine of the earlier Stoics are the philosophical works of Cicero; for their logic, the *Academic Questions;* for their ethics, the treatise *De Finibus*, and the *Tusculan Questions;* and for their theology and physics, the books *De Natura Deorum*, and *De Fato*. See also *Diog. Laert.* l. vii. Plutarch, *Adv. Stoicos*, &c.; Ritter, *Hist. of Ancient Philos.* xi. part 5.

STO'LA. (Gr. στολη.) A dress of which the name was borrowed by the Romans from Greece, but acquired in their language a peculiar signification; being the habit appropriated to women. It was a long vest, coming down to the ankles; was worn within doors, and covered by the palla or cloak when they went out; as described by Horace, *Sat.* l. i. 2.: —

Ad talos stola demissa et circumdata pallâ.

Common prostitutes, at least in the age of Horace, were not permitted to wear this distinguishing garb of the Roman lady. The stole is a robe worn by deacons in the Roman Catholic church. *See* VESTMENTS.

STOLE, GROOM OF THE. An officer of the king's household in the lord chamberlain's department. He is first lord of the bedchamber; his title is derived from the long robe (stola) worn by his majesty on solemn occasions. His original duty, likewise, was to put the king's shirt on of a morning, which, in his absence, devolved on another lord of the bedchamber.

STO'MACACE. (Gr. στομα, *the mouth*, and κακος, *evil.*) A fetor of breath, arising from ulcerated gums. Mouth-washes, with tincture of myrrh and borax, and the internal use of tonics, are the remedies which relieve it.

STO'MACH, *Stomachus*. (Gr. στομα, *the mouth;* and χεω, *I melt*, from its receiving the contents of the mouth and melting them down into nutriment.) The human stomach is a somewhat oblong and rounded membranous bag, situated in the epigastric region. It is largest on the left side (or *cardiac* end), and gradually diminishes towards the right or lower orifice, which is called the *pylorus*. Like the intestines, the stomach has three coats or membranes, connected together by cellular membrane. The exterior or peritonæal coat is a dense firm membrane; the internal or villous coat is soft, mucous, and vascular; the central coat is muscular, and the glands of the stomach are situated between it and the villous coat. The stomach is largely supplied with nerves which come from the eighth pair and sympathetic. The are chiefly from the cæliac, and are accompanied by veins which empty themselves into the vena portæ. The lymphatics of the stomach proceed directly to the thoracic duct. *See* ANATOMY and DIGESTION.

STOMACH PUMP. A small pump or syringe with two apertures, the valves of which are so arranged as to admit of liquids being drawn out of, or injected into the stomach, by means of a flexible tube.

STO'MAPODS, *Stomapoda*. (Gr. στομα, *a mouth;* πους, *a foot.*) The name of an order of the class *Crustacea*, comprehending those in which the maxillary feet are formed like the first four thoracic feet.

STO'MATA. Passages through the epidermis of plants, having the appearance of an areola, in the centre of which is a slit that opens or closes, according to circumstances, and lies over a cavity in the subjacent tissue. They are universally regarded as spiracles or breathing pores.

STONE BORERS; called also *Lithophagi*. Molluscous Bivalves, which, by means of a fleshy foot, on which they turn as on a pivot, perforate or bore into rocks.

STONE-CHAT. A species of warbler, forming the type of the genus *Saxicola* of Bechstein. It is the *Sylvia rubicola* of Latham; *Motacilla rubicola* of Linnæus. Also called the "chick stone."

STONE CURLEW. The name of a large species of plover, the *Ædicnemus crepitans* of Temminck. It appears in England at the latter end of April; frequents open hilly situations; makes no nest, but lays two eggs on the bare ground; and emigrates in small flocks about the end of September.

STONE GALLS. A technical term applied to nodules of clay occurring in sandstone; they often fall out on exposure to weather, and render the stone unfit for architectural purposes.

STONE IN THE BLADDER. *See* CALCULUS.

STOO'KING. The Scotch term for setting up sheaves of corn in stooks, that is, shocks. The operation is performed soon after the corn is cut; it being previously tied into bunches or sheaves.

STOOL. The root of a timber tree, which throws up shoots. Coppice wood consists chiefly of the shoots sent up by the roots of stools of trees or shrubs which have been cut over by the surface. In general all Dicotyledonous trees are endowed by nature with the property of sending up shoots from the stump or stools; but this is not the case with most of the Gymnosperms or Coniferous trees. A wood of pines or firs, therefore, when once cut down, can never be renewed, except by seeds.

STO'RAX. A fragrant balsamic exudation from the *Liquidambar styraciflua*. It is generally much adulterated.

STORK. An English name, equivalent to the *Ciconia* of modern ornithologists. The white stork (*Ciconia alba*) is that species which visits, though rarely, in England.

STORM. The causes of those violent commotions of the atmosphere to which we give the names of storms, tempests, hurricanes, tornados, &c., are involved in great obscurity, chiefly from the difficulty of obtaining a precise knowledge of the various circumstances with which they are accompanied. In order to ascertain the general laws of these phenomena, it would be necessary to determine, in a great number of particular instances, the place and time at which the storm begins and ends, the path it describes, the extent of atmosphere disturbed, the di-

rection and force of the wind, and the barometric pressure at every part of the disturbed column during the whole time of its continuance. But several of these points could only be determined from the comparison of a great number of simultaneous observations on that tract of the earth's surface over which the storm passes; while, from the nature of the thing to be observed, it is evident that a few insulated observations is the most that can be expected in almost any case. Besides, a storm for the most part passes over some part of the sea, where, unless a ship unfortunately happens to be caught in it, no observation can be made, or even evidence be obtained of its existence.

It is in the torrid zone that storms display the greatest violence, and rage with most destructive fury. In our latitudes they are comparatively rare, and in the polar regions they seldom amount to more than a strong wind.

Until recently it was generally believed that during a hurricane the wind at every part of the agitated mass blows in a rectilinear and parallel direction, and a storm was considered to be sufficiently explained when it was described as a wind blowing with a velocity of 100 or 120 miles in an hour. A comparison of the recorded accounts of the circumstances attending several storms has of late years shown that this idea was erroneous, and that the phenomena are considerably more complicated.

Franklin appears to have been the first who remarked that storms travel in a direction opposite to the actual movement of the wind at the time the storm is raging; and he ascribed the phenomenon to a great but partial rarefaction of the air, arising from the sudden precipitation of vapours, or other causes, the consequence of which would necessarily be a simultaneous rush of wind from all quarters to fill up the vacuity; and the mass of air being thus set in motion by a sort of aspiration, the gale will be first felt at those places towards which it blows. (*Letters and Papers on Philosophical Subjects.*) In a work on winds and monsoons, published in 1801, Colonel Capper was led, from a comparison of the details respecting the hurricanes at Pondicherry and Madras in 1760 and 1773, to remark that these hurricanes must have been whirlwinds, whose diameters could not exceed 120 miles, and that the velocity of the wind at any point was due to the rotatory velocity of the vortex. He also supposed that, besides the gyratory movement which forms the characteristic of the whirlwind, a storm has probably also progressive motion. Colonel Capper's speculations, however, appear to have met with little attention until the subject was taken up by Mr. Redfield of New York, who, in a series of papers recently published in the American journals, has diligently collected and examined a great number of observations relative to the storms of the West Indies and North American coasts, and arrived at the similar conclusions. The following general phenomena appear to be established: — 1. The severest hurricanes originate in tropical latitudes to the north or east of the West India Islands. 2. They cover simultaneously an extent of surface from 100 to 150 miles in diameter, acting with diminished violence towards the exterior, and increased energy towards the interior of that space. 3. The tract over which the hurricane passes is not a straight line. South of the parallel of 30° north latitude, it proceeds in a westerly course inclined to the north; but when it comes to about this parallel, it changes rather abruptly to the north and eastward, and continues to incline gradually more to the east. The average progressive velocity appears to be from fifteen to twenty-five miles per hour. 4. The duration of a storm at any particular place depends of course on the extent of the mass of agitated air, and the progressive velocity; and storms of smaller extent move with even greater rapidity than large ones. 5. The direction of the wind in a hurricane is not in the direction of its progress. When the progressive motion of the storm is westward, the wind at the commencement is from a northern quarter, and during the latter part of the gale from a southern quarter of the horizon. When the progressive motion is eastward, the phenomena are reversed; the wind blows at first from a southern quarter, and towards the end of the gale from a northern quarter of the horizon.

From these phenomena, and particularly the last, Mr. Redfield concludes that the great body of the storm whirls in a horizontal circuit round a vertical or somewhat inclined axis of rotation, which is carried forward with the storm; and that to a spectator placed at the centre the direction of the rotation is invariably from *right to left*. It is to be understood, however, that the phenomena now described and the conclusion drawn from them apply only to the northern hemisphere.

Another fact deserving of attention is, that the barometer, in all latitudes, sinks during the first half of the storm in every part of its track, and rises during the second. This phenomenon is ascribed to the effects of the centrifugal force of rotation; and such is the regularity of its occurrence, that it has been considered as affording of itself a strong proof of the rotatory character of the motion.

Colonel Reid of the engineers having been officially employed to restore the government buildings at Barbadoes blown down by the great hurricane of 1831, was led to investigate the subject generally; and in his work, entitled *An Attempt to develop the Laws of Storms, &c.*, he has collected and given the results of an immense number of details, obtained from an examination of ships' logs furnished to him by the admiralty, and other sources. These results he considers as confirming in all respects the conclusions of Mr. Redfield respecting the gyratory motion of the gale from right to left; its progressive motion in a curve line, first westward, and then towards the north and east; the position of the vertex of the curve at or near the 30th degree of latitude; and the fall of the barometer during the first half of the storm, and its rise during the second. Colonel Reid has also given an account of several great hurricanes in the southern hemisphere, from which it appears that the southern storms follow exactly the same laws as the northern, but in a reversed order. The direction of the rotation is from *left to right;* the centre of the gyrating mass advances first eastwards, then turns towards the south, and falls off towards the south-west and west, the vertex of the curve being at the 30th degree of south latitude. In the northern hemisphere, the West Indies and Atlantic coast of North America appear to be the places where storms most frequently rage; in the southern, the focus of storms appears to be placed near the Mauritius.

The uniformity of the direction of the rotatory motion of the hurricane, and its opposite direction in the opposite hemispheres, was explained by Mr. Redfield from theoretical considerations respecting the origin of storms, which he supposes to be produced by the mingling and collision of two atmospherical currents near the outer border of the trade winds; namely, the superior or equatorial stream, and the polar stream, which constitutes the trades. On looking at the curves representing the paths of the hurricanes on the charts projected by Mr. Redfield and Colonel Reid, it is difficult not to believe that the direction of their progressive motion is mainly determined by the configuration of the American continent.

The fact of the whirling character of storms has been controverted by Mr. Espy, another American writer on the subject, who advocates Franklin's theory of progressive motion in radial lines. Mr. Espy states, that on comparing simultaneous observations in the middle of storms and all round their borders, he found that the wind blows *inward* on all sides of a storm towards the central parts, — towards a point, if the storm be round; and if oblong, towards a line extending through its greatest diameter; and that he had traced the effects of seventeen storms, without finding a single exception to the general rule. Professor Bache of Philadelphia maintains the same opinion; and has described a tornado which occurred at New Brunswick in 1835, in which he could find no proof of rotation, the objects thrown down by the wind being all directed to a centre. It is not improbable that there may be hurricanes of both characters. An outline of Mr. Espy's theory is given in the *Report of the British Association for* 1840.

Independently of the interest which attaches to the subject in a meteorological point of view, a knowledge of the general laws which regulate the phenomena of storms would be of immense importance, inasmuch as it would enable the navigator to avoid those tracts of the ocean in which they chiefly prevail at particular seasons, or at least, if surprised by a storm, to steer on the course by which he may soonest escape from it or fall into its wake. On either theory the direction of the wind at the commencement of the gale must indicate, with considerable certainty, the quarter where the storm is raging with greatest fury. (See, in addition to the works already cited, *Silliman's Journal* from 1831; Prof. Forbes's Reports on Meteorology, in the *Reports of the British Association* for 1832 and 1840; and the *Edin. Review*, vol. lxviii.) See also WIND.

STO'RTHING. The parliament of Norway. It is elected once in three years, and sits every year for the despatch of business. The election is double; every qualified person (an owner or liferenter of land paying taxes in the country, and every one possessing land or houses of 150 rix dollars value in towns) joining in the election of councillors, who elect out of their own body the representatives of the country. These must be from 75 to 100 in number. The storthing, when elected, divides itself into two houses: one fourth, chosen by the rest, joining the laything, or upper house; the remainder the odelsthing, or lower house. The storthing has the usual powers of a legislative assembly in a constitutional country, and the king has only a suspensive veto; which, if the storthing passes a law three times in six successive years, becomes of no effect.

STORY. In Architecture, a subdivision of the height of a house, comprehending the height ascended by one flight of stairs.

STORY POST. In Architecture, a vertical post to support a floor or superincumbent wall.

STOVE. (Dutch, *stove*.) A receptacle for the combustion of fuel for the purpose of heating houses, &c. The common fire-grate for the combustion of coal, with its various appendages, is generally called a *stove;* hence *register stoves*, *Bath stoves*, &c. These are often, and indeed generally, very unscientifically constructed, and calculated to consume a large quantity of fuel, with a proportionate waste of heat. They are generally intended to diffuse warmth principally or entirely by *radiation*, and should be placed as near the ground as possible; while the different parts into the contact of which the burning fuel is brought should be of fire-brick, or some similar composition, which is a bad conductor but a good radiator of heat. It is manifest that in our common fireplaces the enormous volume of hot air which passes up the chimney is not available as a source of heat; hence, in colder climates, and where greater economy of fuel is studied, the fireplace is frequently closed in, and contained in an iron box which projects into the room, while the heated air before it finally enters the chimney is made to circulate through tubes or pipes, to which it communicates much of its excess of heat, and these again impart it to the surrounding air. What are termed *German stoves* are usually made upon such principles; and in them the fuel is often introduced, and the air required for the support of its combustion admitted, on the outside of the room in which the stove with its flues and heating surfaces is placed.

In *Arnott's stoves* the heat is similarly but more scientifically economized. There is only enough air admitted to keep up the slow combustion of the fuel, and the heat is communicated to the radiating surfaces of the stove; so that before the air which has passed through the fuel finally enters the chimney it has been deprived of the greater part of its available heat. These stoves are also so constructed as, by means of thermometric or self-acting registers, to adjust with much nicety the supply of air, so that neither more nor less may enter than is required to maintain the combustion of a given quantity of fuel.

In *Feetham's air-stoves* the common open fire is retained; but the heat is to a certain extent economized by by causing the hot air before it enters the chimney to communicate a portion of its heat to an iron box, over which a current of air passes and is sent warm into the room.

It is manifest that our common open fires must act as powerful ventilators, and that the large quantity of air which is driven up the chimney must be supplied in some way or other through the apartment in which the fire is burning. This supply of air is generally left to chance, and finds its way into the room by crevices in the doorways and window sashes, or between the boards of the floor, or any similar accidental passage through which it can make its way; and as, in London at least, the air always abounds in fuliginous particles, these are carried in along with it, and show its track by the blacks which it deposits. If this supply of air is inadequate, and it generally is so in new and well-built houses, in consequence of the tightness of the doors, windows, and floors, the chimney of necessity smokes, and the door or window requires to be left open to prevent such an effect. This evil may usually be effectually prevented by admitting fresh air from without through some proper and adequate channel, and various ornamental or concealed apertures may be contrived for the purpose; in the best arrangement of which, however, much practical as well as theoretical skill is often essential.

When rooms are warmed by German or Arnott's stoves, the ventilating powers of which are very inferior to the open grate, *ventilation* requires to be strictly attended to. Where buildings are warmed by currents of hot air sent up from stoves on the basement story, great attention should also be paid to ventilation; and in such cases the leading object should be to send in a large volume of air very moderately heated (to about 100°), rather than a small quantity of very hot air: the latter does not readily mix with the surrounding cold air, but forms a distinct and rapidly ascending column, which does not diffuse itself where most wanted; and it is apt to have a disagreeable and burned odour, arising from the charring of the particles of organic dust which are carried with the air over the too highly heated surfaces of the stove or flues. A little aqueous vapour, sent in along with the warm air by placing a saucer of water in some convenient situation, is often effectual in preventing the disagreeable sensation occasioned by respiring too dry an atmosphere.

Stove. In Horticulture, a structure in which plants are cultivated that require a considerably higher temperature than the open air in Britain and similar climates. There are two or three kinds of stoves, but the principal are the dry stove and the damp stove. The dry stove is a structure, the atmosphere of which is heated to the temperature of from 55° to 60° during winter, in which are chiefly cultivated succulents; such as the different species of *Ceretus*, *Cereus*, *Staphelia*, *Euphorbia*, *Mesembryanthemum*, and other succulents having similar habits. During winter these plants require very little water, and during summer they require intense heat, and abundance of air and water during fine weather. The damp stove, sometimes also called the bark stove, requires a temperature of between 60° and 70° during winter, with a proportionate increase during summer; accompanied, in both seasons, with a high degree of atmospherical moisture. This moisture is produced partly by evaporation from the bark bed in which the plants are plunged, but chiefly by watering the floor of the house, and by syringing the plants. During summer the plants in the bark stove require all the light which the atmosphere in this country is capable of producing, together with abundance of air, as in the dry stove. Both stoves are heated by smoke flues, or by hot water or steam, circulated in metallic or other tubes. The plants cultivated in the moist stove are exclusively those of the tropics; and those which require the highest degree of heat are chiefly Monocotyledonous plants, such as the *Scitamineæ*, which include the ginger, plantain, banana, sugar cane, palms, *Orchidaceæ;* and such Dicotyledonous plants as the bread fruit, the yam, mangosteen, and other East Indian plants. The bark bed is chiefly employed for producing a uniform degree of moisture and heat to the roots, and also as a reservoir of heat for the atmosphere of the house in case of any diminution from the flues, water or steam pipes, or the sun. Stoves of every description require a constant degree of attention from the gardener throughout the year, more especially such as are devoted to the palms, the banana, the pine apple, and the *Orchidaceæ*.

STRABI'SMUS. (Gr. *στϱαβιζειν*, *to squint*.) An unnatural obliquity in the axis of the eye, arising from various causes. It may often be, to a great extent, overcome, especially in children, by blindfolding the sound eye, presuming one only to be affected. In very bad cases, especially those of squinting inward, and such are by far the most common, an operation which has lately been introduced is often effectual in greatly relieving the deformity; it consists in dividing the internal rectus muscle of the eyeball, which is done by a proper scissors without externally wounding the eyelid.

STRAIGHT ARCH. In Architecture, the arch over an aperture, whose intrados is straight, but with its joints drawn concentrically, as in a common arch.

STRAIGHT JOINT FLOOR. In Architecture. *See* Floor.

STRAI'NING PIECE. In Architecture, a piece of timber, whose office is to prevent the nearer approach of two pieces of timber in an assemblage of framing; such is the collar in a queen post roof. *See* Roof.

STRAIT, in Geography, signifies a narrow pass or frith separating one country from another.

STRA'MONY, or THORN APPLE. The *Datura stramonium:* an indigenous narcotic plant, the seeds and leaves of which are used in medicine. The dried leaves are occasionally smoked, like tobacco, for the relief of spasmodic asthma; and an extract of the seeds is used as a sedative in some painful chronic affections. *See* Daturia.

STRA'NGURY. (Gr. *στϱαγξ*, *a drop*, and *ουϱον*, *urine*.) A difficulty in voiding urine.

STRATH, in Scotland, is generally understood to signify a valley of considerable size, whose appellation is determined by some river running through it, or some particular characteristic.

STRA'TUM. When different rocks lie in succession upon each other, each individual forms a *stratum*. *See* Geology.

STREAK. The appearance which arises from scratching a mineral with the point of a knife. The streak is *similar* when the colour of the scratch is the same as that of the mineral, but *dissimilar* when the colour varies.

STREAM TIN. Native oxide of tin, or tinstone, which is found in rounded particles and masses, mixed with other alluvial matters. The finest grain tin is procured from this ore.

STRE'LITZ. (Rus. plural strelitzy, said to be derived from strelai; It. strale, *an arrow*.) A soldier of the ancient Muscovite militia was so called. The strelitzy were the only standing army of the empire; and, like the Turkish janissaries, constantly interfered with its government. Their last revolt was in 1698, during the absence of the Czar Peter I., who, on his return, cashiered the corps altogether.

STRENGTH, in Mechanics, is used in the same sense as force or power. Thus strength of animals is the muscular force or energy which animals are capable of exerting; strength of materials is the resistance which bodies oppose to a force acting upon them.

Strength of Animals. — It is obviously a matter of much importance to be able to estimate with tolerable accuracy the effort which an animal of the average strength employed in labour is capable of exerting, and accordingly very numerous observations have been made on the subject; but this species of force is subject to

variation from so great a number of circumstances, both physical and mechanical, that the results given by different authors present very little agreement with each other, though they are of great value as affording data for determining the modes in which animal labour is most advantageously employed.

The force which an animal is capable of exerting against an obstacle is greatest when the animal stands still. When it begins to move, a considerable part of its strength is expended in the transference of its own body; and the greater the velocity with which it moves, the less will be the load which it is capable of transporting. There must, also, be a certain velocity at which it can only move when it carries no load. Now, if from the total effect of the muscular force exerted we subtract the part which represents the transference of the weight of the animal's body, the remainder, which is called the *useful effect*, will be obviously measured by the load which the animal is capable of transporting to a given distance in a given time; therefore, putting w = the weight, v = the velocity, and t = the time, the useful effect is represented by the product $w\,v\,t$, and will be greatest when this product is a maximum. In order to determine this maximum it is necessary to establish a relation between w and v (for the time t may be taken as unity). The empirical formula given by Euler for representing the relation between the load and the moving power in machines generally may be adopted for this purpose, as it has been found to agree tolerably well with experiment. Let P denote the power of the animal, or the greatest load it is capable of moving, and c the greatest velocity with which it can move unloaded; then the equation between w and v is $w = \mathrm{P}\left(1 - \frac{v}{c}\right)^2$; and the product $w\,v$ becomes a maximum when $3\,v = c$, or v is one third of c. *See* MACHINE.

In order to compare the effects produced by different animals, or by the same animal under different circumstances, it is usual to express the effect numerically in terms of some conventional unit, which, as being the measure of a force, is called the *dynamic unit*. Thus, in the product $w\,v\,t$, we call w = 1 lb., v = 1 foot, and t = 1 minute; the measure of the force will be the effort necessary to raise or transport a pound through one foot of space in one minute of time. For example, Desaguliers asserts that a man can raise a hogshead of water 10 feet high in a minute. Now a hogshead of water, vessel included, weighs about 550 lbs.; and 550 lbs. raised through 10 feet must require the same exertion of muscular force as 5500 lbs. raised through one foot; therefore, the useful effect, which in this case is the whole effort, as the man stands still, is expressed by 5500 dynamic units, and may thus be compared with any other effort which is capable of being similarly expressed. Instead of a pound, a foot, and a minute, we might assume a hundred weight, a yard, a day, or any other denominations that may be convenient.

Strength of Men. — The measure of human force has been the subject of numerous experiments, principally by Desaguliers, Lahire, Guenyveau, Coulomb, Schulze, Buchanan, &c., whose results may be found in most treatises on practical mechanics. These results differ very widely, as indeed might be expected, considering the very great differences of the force which different individuals are capable of exerting, — differences which depend not only upon age, constitution, and habit, but even upon climate, temperature, and food.

Of the different modes of estimating human strength, the most practically useful is the observation of the average effect produced daily by a labourer who continues his exertions for a number of successive days. We shall state a few of the results; and for the sake of comparison reduce them to dynamic units, assuming the unit to be 1000 lbs. avoirdupois transported to the distance of one foot in one minute.

According to Coulomb, a man walking on a level road may travel at the rate of 30 miles per day, or 264 feet per minute, and continue his exertions 10 hours a day. Taking the weight of the man at 150 lbs., the quantity of action is 23,760 dynamic units.

If instead of walking on a level road he mounts a stair, the velocity is reduced to 26·4 feet per minute, and the labour can be continued only 8 hours a day. In this case, the effect produced is 1901 dynamic units.

A man walking on a level road, and carrying on his back a weight of 90 lbs., travels at the rate of a mile and a half per hour, or 132 feet per minute, and continues his exertions 7 hours per day. The *useful effect* is consequently 4989 dynamic units.

A man climbing a stair, and carrying on his back a load equal to his own weight or 150 lbs., proceeds at an average rate of only 7 feet per minute, during 6 hours a day. The useful effect is consequently 378 dynamic units.

A labourer transporting materials in a wheelbarrow, and returning unloaded for a fresh burden, transports a load of 130 lbs. with a velocity of 90 feet per minute, working 10 hours a day. The useful effect is consequently 7020 dynamic units.

The force which a man exerts in dragging a load has been variously estimated. Schulze estimates the absolute effect, or that which the man can exert for a short time without moving, as equal to a pressure of about 107 lbs.; Bernoulli at 75 lbs.; and Guenyveau found the absolute force of traction, when exerted by means of a rope passing over the shoulder, to be from 110 to 132 lbs. Allowing the accuracy of Euler's formula above given, and assuming the action to be a maximum when the velocity is 2 miles per hour, we shall have $c = 6$; and if we also assume the absolute force P = 72 lbs., then the formula will become $w = 2\,(6 - v)^2$, in which w represents the number of pounds corresponding to the force developed when the velocity is v miles per hour. Thus when $v = 0$, we have $w = 72$ lbs.; when $v = 2$, we have $w = 32$ lbs.; and when the velocity is 4 miles per hour, the force of traction becomes 8 lbs. In the extreme cases the formula is inaccurate, but for moderate velocities it affords a tolerable approximation.

The greatest velocity with which a man can walk for a length of time, having no load to drag, is, according to Schulze, 5·37 feet per second; according to Bernoulli, 6·56 feet; according to Guenyveau, from 6·56 to 9·84 feet per second, or from $4\frac{1}{2}$ to $6\frac{2}{3}$ miles per hour.

According to Mr. Buchanan (*Repertory of Arts*, vol. xv.), the effective strengths of men in working a pump, in turning a winch, in ringing a bell, and rowing a boat, are respectively as the numbers 100, 167, 227, 248. The last is one of the most advantageous modes in which human force can be exerted.

Porters in London carry from 200 lbs. to 300 lbs. at the rate of 3 miles per hour; chairmen walk at the rate of 4 miles an hour with a load of 150 lbs. each; and it is said that an Albanian porter will carry from 700 to 900 lbs., stooping forward and assisting his steps with a short staff.

The following results of experiments on the comparative strength of men of different countries, with Regnier's dynamometer, are given by M. Peron: — England, 71·4; France, 69·2; Timor, 58·7; Van Dieman's Land, 51·8; New Holland, 50·6.

Strength of Horses and other Quadrupeds. — Of all animals employed as first movers, the horse is, beyond question, the most useful, and that whose labour is susceptible of the most numerous and varied applications. It is therefore very important to ascertain his average force; and accordingly a great number of estimates have been published, both of the amount of labour he is capable of performing, and of his absolute muscular power. For the purpose of determining the latter, the dynamometer may be conveniently used; but as the action of the animal is very quickly reduced by continued exertion, it is more usual to estimate it according to the amount of daily labour performed. Desaguliers and Smeaton estimate the strength of a horse as equivalent to that of five men; the French authors have commonly stated it as equal to that of seven men; and Schulze makes it equal to that of fourteen men in drawing horizontally. According to Desaguliers, a horse's power is equivalent to 44,000 lbs. raised 1 foot high in one minute; Smeaton makes this number 22,916, Hachette 28,000, and Watt 33,000. This last estimate is what is commonly understood by the term *horse power* as applied to steam engines.

The quantity of action which a horse can exert diminishes as the duration of the labour is prolonged. Tredgold gives the following table, showing the average maximum velocity with which a horse unloaded can travel, according to the number of hours per day: —

Time of March, in Hours.	Greatest Velocity per Hour, in Miles.	Time of March, in Hours.	Greatest Velocity per Hour, in Miles.
1	11·7	6	6·0
2	10·4	7	5·5
3	8·5	8	5·2
4	7·3	9	4·9
5	6·6	10	4·6

The useful effect a horse is capable of producing depends much on the manner in which his strength is applied. One of the best modes is to make him draw a loaded carriage. The carriers in Scotland usually transport in a single-horse cart weighing about 7 cwt. the load of a ton, and travel at the rate of 22 miles per day. Neglecting the weight of the animal and of the cart, and supposing the journey to be accomplished in 10 hours, the useful effect reduced to dynamic units (1000 lbs. one foot in one minute) is 260,198 dynamic units.

Navier gives the following results: — A horse drawing in a cart a load of 1540 lbs. (700 kilogrammes) travels at the rate of $216\frac{1}{2}$ feet per minute, during 10 hours per day. Here the useful effect is 200,046.

A horse harnessed in a coach, and drawing a load of 770 lbs. avoirdupois, goes at a trot at the rate of 433 feet per minute, during $4\frac{1}{2}$ hours per day. The useful effect is consequently 90,020.

A horse carrying on his back a load of 264 lbs. can travel at the rate of 216⅔ feet per minute, 10 hours a day. The useful effect is 34,294 dynamic units. Going at a trot with double the velocity, during 7 hours a day, and carrying a load of 176 lbs., the useful effect is 32,007.

A horse harnessed in a mill, going at a pace of 195 feet per minute, and exercising a force equal to a pressure of 99 lbs., during 8 hours a day, produces a useful effect represented by 9266 dynamic units.

On the strength of mules, oxen, and the other animals employed in industry, there are few correct observations. The following are the principal results. Taking the useful effect of the daily labour of a man according to Coulomb's estimate as unity, then the comparative effects of the labour of some of the other animals applied in the same manner are thus estimated: —

For carrying loads in a horizontal plane.

Strength of a man	1	(Coulomb.)
— of a horse	4·8	(Brunacci.)
— of a horse	6·1	(Wesermann.)
— of a mule	7·6	(Brunacci.)

For transporting burdens with a wheel carriage.

Man with a barrow	1	(Coulomb.)
Horse in a 4 wheel waggon	17·5	(Wesermann.)
Horse with a cart	24·3	(Brunacci.)
Mule with a cart	23·3	(Brunacci.)
Ox with a cart	12·2	(Brunacci.)

The above comparisons are probably nearer the truth than the following, which are usually quoted from Hassenfratz (*Encyclopédie Méthodique*): —

In carrying loads on a horizontal plane.

Strength of a man	1	Strength of a dromedary	25
— of a horse	8	— of an elephant	147
— of a mule	8	— of a dog	1
— of an ass	4	— of a reindeer	3
— of a camel	31		

In drawing a weight along a horizontal plane.

Strength of a man	1	Strength of an ox	4 to 7
— of a horse	7	— of a dog	0·6
— of a mule	7	— of a reindeer	0·2
— of an ass	2		

On the subject of animal power and the best modes of its employment, reference may be made to the following works: — Coulomb, *Sur la Force des Hommes* (*Mém. de l'Acad.*); Prony, *Architecture Hydraulique;* Hachette, *Traité des Machines;* Guenyveau, *Essai sur la Science des Machines;* Coriolis, *Calcul. de l'Effet des Machines;* Borgnis, *Traité de la Composition des Machines;* Wesermann, *Taschenbuch für Strassen und Wegbaubeamte.*

STRENGTH OF MATERIALS. The force with which a solid body resists an effort to separate its particles, or destroy their aggregation, can only become known from experiment; nevertheless, if we assume an hypothesis to represent the manner in which the elementary particles are arranged and cohere, general formulæ may be deduced, which will represent the comparative strength of bodies of different forms and dimensions, or submitted to the action of forces applied in different manners, and will consequently be of great use in practical mechanics.

There are four different ways in which the strength of a solid body may be exerted: first, in resisting a longitudinal tension, or force tending to tear it asunder; secondly, in resisting a force tending to break the body by a transverse strain; thirdly, in resisting compression, or a force tending to crush the body; and fourthly, in resisting a force tending to wrench it asunder by torsion. We shall consider these separately.

1. *Longitudinal Tension.* — The resistance opposed by a solid body to a longitudinal strain is usually termed the *absolute strength*, or force of direct cohesion, of the body. Two points may be proposed for investigation: first, to determine the quantity by which a body of a given length is stretched or elongated under the action of a given force or weight; and secondly, the effect required to separate the parts or produce rupture. Experiments have usually been directed to the last of these only, but the first may be determined indirectly from experiments on flexure. In bodies of a fibrous structure, as the woods, the cohesive force differs greatly, according as the effect is applied in the direction of the fibres, or at right angles to it. When the strain is exerted in the direction of the fibres, the cohesive force obviously depends on two circumstances only — the strength of each fibre, and their number; and in general, in bodies of the same substance and structure, the strength is proportional to the transverse area of the body, and to a certain constant which must be determined by experiment.

Suppose the body to be a prism or cylinder, and let A be the area in square inches of a section perpendicular to its length, or to the direction of the force; W the weight in pounds which produces rupture; and s the absolute strength of the substance, or the weight in pounds which would overcome the cohesive force of a rod whose transverse section is one square inch; then $W = s\,A$, or $s = W \div A$. In a rectangular beam whose breadth and thickness are respectively a and b, we have $A = a\,b$; whence $W = s\,a\,b$, $s = W \div a\,b$. In a cylindrical rod whose radius is r, we have $A = \pi r^2$ ($\pi = 3{\cdot}14159$); whence $W = s\,\pi r^2$, and $s = W \div \pi r^2$.

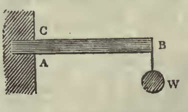
Under the term COHESION we have already given a table of the values of s in respect of different woods and metals. For further information, the reader is referred to *Barlow's Treatise on the Strength of Timber, &c.* (1837); but a much more ample collection of experimental results will be found in the work of Navier, *Resumé des Leçons, &c., sur l'Application de la Mécanique à l'Etablissement des Constructions et des Machines.* We may remark, that although the longitudinal tension is, with respect to mechanical action, the simplest of all the strains to which a solid body can be subjected, it is the most difficult to submit to experiment, by reason of the enormous forces required to produce rupture, and, in the case of fibrous bodies, the difficulty of applying those forces in the direct line of the fibres. If the fibres are not all subjected to the same strain, it is obvious that the direct cohesion will be estimated at less than its real value; and, as Mr. Barlow remarks, it is probably owing to this circumstance that so little agreement is found in the results of experiments.

2. *Transverse Strength.* — When a body suffers a transverse strain, the mechanical action which takes place among the particles is of a more complicated nature. Galileo was the first who attempted to give a rational explanation of this action, and to submit the strength of the materials used in the mechanical arts to the measures of geometry and arithmetic. He assumed that all solid bodies are composed of numerous small parallel fibres, perfectly inflexible and inextensible; and that when they break the several fibres give way in succession, the body turning on the last which give way as on a hinge, and the strain on each fibre, previous to the rupture, being proportional to its distance from the quiescent fibres. From this it follows that the resistance of a beam to a transverse strain is in the compound ratio of the strength of the individual fibres, the area of the cross section, and the distance of the centre of gravity of the cross section from the points round which the beam turns in breaking.

The first who attempted to submit the theory of Galileo to actual experiment was Mariotte, whose results were published in his *Traité sur les Mouvements des Eaux*, 1680. These experiments attracted the attention of Leibnitz, who, in the *Acta Eruditorum* for 1684, pointed out defects of the theory, and proposed a different hypothesis. Leibnitz assumes that every body before it breaks admits of a certain degree of extension, and consequently the fibres are neither inflexible nor inextensible. He further assumes a principle first proposed by Hooke; namely, that the strength of each fibre under the action of a straining force varies with the degree of extension, or is proportional to the distance of the fibre from the fixed point about which the beam is supposed to turn. In this hypothesis, the beam is still supposed to turn about its upper or lower edge, or that all the fibres, excepting the quiescent ones, are in a state of tension; although it had been remarked by Mariotte (and is indeed sufficiently obvious), that when flexure takes place part of the fibres only are in a state of tension, another part being compressed, so that the line about which the beam turns is somewhere within the section of fracture. Professor Robison appears to have been the first who distinctly showed that the position of the *neutral axis* is a necessary datum in the solution of the problem.

Although it cannot be doubted that the hypothesis of Galileo is at variance with the precise fact, yet it is found to be sufficient for practical purposes; and indeed the results which it gives appear to agree nearly as well with experiment as those which are derived from a more refined theory and more elaborate calculations. It has, therefore, on account of its great simplicity, been very generally adopted by writers on mechanics. We shall here briefly state the principal results.

Suppose a prismatic beam A B to have one end firmly fixed in a wall, and a weight W to be suspended from the other end, the beam lying horizontally. According to the hypothesis, the fibres are inflexible and inextensible, so that no bending takes place; and when the rupture commences the fibres first give way at the upper side C, and the beam turns about A as upon a hinge. The two forces brought into action are, therefore, the weight W acting at the end of the lever A B, and the resistance of the particles in the section A C; and at the instant previous to the rupture the two forces are in equilibrio, or their respective moments of rotation are equal. Now, the resistance of any fibre in the section A C is the absolute strength of the fibre multiplied into its distance from the point A; therefore the whole resistance of the beam is formed by multiplying each differential element of the area into its distance from the point A, and into the abso-



lute strength, and taking the sum of all the products. But this is equivalent to the product of the area of the section by the distance of its centre of gravity from A, and by the absolute strength; hence if we put $A =$ the area of the section, $c =$ the distance of its centre of gravity from the lowest point, $s =$ the absolute strength of the unit of surface, the resistance to fracture is $s\,c\,A$. Let $W =$ the breaking weight in pounds, and $l = A\,B$, the length of the beam; then the moment of the force tending to produce fracture is $W\,l$, and the equation of equilibrium is $W\,l = s\,c\,A$; whence $W = s\,c\,A \div l$, or $s = W\,l \div c\,A$.

In a rectangular beam whose breadth is b, and thickness or depth d, we have $A = b\,d$, $c = \frac{1}{2}\,d$; whence $W = s\,b\,d^2 \div 2\,l$; or the strength of the beam is directly as its breadth and the square of its depth, and inversely as its length.

In a square beam $b = d$, whence $W = s\,b^3 \div 2\,l$.

In a square beam whose diagonal is vertical, we have $A = a^2$, and $c = \frac{1}{2}\,a\sqrt{2}$; whence $W = s\,a^3\sqrt{2} \div 2\,l$. The beam ought, therefore, to be stronger in this position; but this result of the theory is contradicted by experience.

If the beam be cylindrical, and r be the radius of its section, then $A = \pi\,r^2$, and $c = r$; whence $W = \pi\,s\,r^3 \div l$.

In a cylindric tube, the radii of whose external and internal surfaces are respectively r and r', we have $A = \pi\,(r^2 - r'^2)$, $c = r$; whence $W = \pi\,s\,r\,(r^2 - r'^2) \div l$.

From the two last cases it may be shown that the strength of the tube is to the strength of the same quantity of matter formed into a solid cylinder in the ratio of r to $\sqrt{(r^2 - r'^2)}$; so that a tube may be much stronger than the same quantity of matter in a solid form. This principle furnishes an explanation of many facts in the economy of nature. To obtain the greatest strength with the least possible weight, the bones of animals and the quills and feathers of birds have the form of hollow tubes; and the same arrangement is observed in many of the vegetable tribes, as the *Gramina*.

In the preceding formulæ the weight of the beam is neglected, as inconsiderable in comparison of the weight applied; but since in similar beams of the same substance the strength increases as the square of the depth, while the weight increases as the cube, there is consequently a limit, which if a beam of a given shape and of a given materials were to reach it could only bear its own weight, and would be broken by any further increase.

Suppose a beam A B to be laid horizontally on two props, and to be broken by a weight placed at equal distances between them, the pressure will be equally shared between the props; and since by the hypothesis fracture takes place without bending, the effect will be the same as if the beam had been fixed at the middle, and each end acted upon by a force equal to half the weight, but directed upwards. The breaking weight is consequently double of that which would be required to break a beam of half the length having one end fixed in a wall; or the transverse length of the beam when supported at one end is four times as great as that of the same beam supported at one end only, and having the weight suspended from its other extremity. In this case, therefore, when the beam is rectangular, $W = 2\,s\,b\,d^2 \div l$; when the beam is square, $W = 2\,s\,b^3 \div l$; when cylindrical, $W = 4\,\pi\,s\,r^3 \div l$; and so with the other cases.

When the horizontal beam, instead of being merely supported, is firmly imbedded in a wall at each end, the resistance will be equal to that of the same beam merely supported at each end, added to the resistance of two beams of half the length fixed at one end only, and acted upon by half the weight. For it is manifest that three fractures must take place,—one in the middle, and one at each end; and the strain in the middle is equal to that of the supported beam, which has just been shown to be $2\,s\,b\,d^2 \div l$; and that at each end is one fourth of this, or $\frac{1}{2}\,s\,b\,d^2 \div l$; therefore the whole weight W, under which if suspended from the middle the beam will give way, is $W = 3\,s\,b\,d^2 \div l$.

On the same principle it may be shown that when a beam is supported at both ends, the weight which it is able to bear at any point is inversely as the rectangle under the segments into which it is divided by that point. Hence a beam supported at both ends is weakest in the middle, the rectangle under the segments at that point being a maximum. It also follows that when the pressure is equally distributed over the whole beam, twice the weight will be required to break it.

When the beam, instead of being laid horizontally, is inclined, its strength is increased in the ratio of unity to the square of the cosine of the angle of inclination. This consequence of the theory, however, can obviously hold only within certain limits; inasmuch as it would give the strength equal to infinity when the inclination is a right angle, or when the load is applied endwise.

In the hypothesis of Galileo, from which the preceding results have been deduced, the beam is supposed to be absolutely inflexible, which is not the case with any material substance; and although the results are sufficiently accurate in their application to architectural or mechanical purposes, yet in the comparison of experiments to determine the ultimate strength of different substances it becomes necessary to take the elasticity and consequent incurvation into the estimate. Mr. Barlow, assuming that the flexure takes place only at the section of fracture, and that the fibres remain inextensible in every other point, deduces the following formulæ for the transverse strain, which agree very well with the experiments.

As before, let l denote the length, b the breadth, and d the depth of the beam, all in inches; and let Δ be the angle of deflection, W the breaking weight, and S the resistance of a rod whose section is one square inch, W and S being expressed in pounds; then,

1. When the beam is fixed at one end and loaded at the other, $S = W\,l\cos.\Delta \div b\,d^2$;

2. When the beam is supported at each end, and loaded in the middle, $S = W\,l\sec.^2\Delta \div 4\,b\,d^2$;

3. When the beam is fixed at each end and loaded in the middle, $S = W\,l\sec.^2\Delta \div 6\,b\,d^2$.

The angle of deflection being small, its secant in the ordinary applications may be considered as equal to unity; and if we also write $\frac{1}{2}\,s$ instead of S in the above formulæ, they will become the same as those deduced from the hypothesis of Galileo.

The preceding results have reference to the absolute strength of the beam, or to the weight which it can just support without being broken; but it is also very important to know the amount of deflection which a given weight will produce in a beam of a given material and of given dimensions. Suppose a prismatic beam to be firmly fixed at one end, and to have a weight suspended from the other; then, if we adopt the hypothesis that the extension of the fibres at each point is proportional to the straining force, the curvature at the different points and the law of the action which takes place may be deduced from the properties of the elastic curve. (*See* Elastic Curve.) The following results of theory are confirmed by the experiments of Dupin and Barlow.

1. The deflections of a beam loaded with different small weights are proportional to those weights. 2. The deflection, *ceteris paribus*, is directly as the cube of the length, inversely as the cube of the depth, and inversely as the breadth. Hence if l denote the length, b the breadth, d the depth, and k the deflection (that is, the distance to which the loaded end of the beam is drawn below the horizontal line), all expressed in inches, and if w be the weight in pounds which the body can support without its elasticity being impaired, then k is proportional to $w\,l^3 \div b\,d^3$; or if we assume E as the constant modulus of elasticity, $E = w\,l^3 \div k\,b\,d^3$.

The deflection of a beam fixed at one end and loaded at the other is double that of a beam of twice the length supported at both ends and loaded at the middle with a double weight, supposing the strain to be the same in both cases; consequently, when the weights are the same, the deflection in the first case is to that in the second as 4 : 1; and when the length and weight are both the same, the deflections (which vary as the cubes of the lengths) will be to each other as 32 : 1. In the case of the beam supported at both ends, the formula therefore becomes $E = w\,l^3 \div 32\,k\,b\,d^3$.

From the table of *data* given by Barlow (*Strength of Timber*, p. 150.) we extract the following mean results of experiments (on beams supported at both ends), made in the dock-yard at Woolwich, for determining the elasticity and strength of various species of timber.

Description of Wood.	Elasticity. $E = \dfrac{w\,l^3}{32\,k\,b\,d^3}$	Strength. $S = \dfrac{W\,l}{4\,b\,d^2}$

From the mean of a number of experiments by Tredgold the values of E and S, for rectangular cast iron bars, were found to be $E = 2254000$, $S = 7620$.

3. *Resistance of Bodies to Forces tending to crush them.* — The resistance of a body to a crushing force might be supposed, *à priori*, to follow the same law as the absolute force of cohesion, and consequently to depend only upon the area of the section and the force of aggregation of the

particles. It is found, however, by experiment, that the thickness of the body (or length, if the force is applied endwise) has an important influence on the amount of pressure it is capable of bearing. Very thin plates are readily crushed; and the resistance appears to increase with the thickness up to a certain maximum, after which it diminishes. The theory of the resistance of pillars, which is of great importance on account of its application to architectural purposes, was investigated by Euler; and, according to the hypothesis adopted by him, the strength varies directly as the fourth power of the diameter or side, and inversely as the square of the length. This is confirmed by the recent experiments of Mr. Hodgkinson (*Phil. Trans.* 1840) in respect of pillars of wrought iron, or timber; but in the case of pillars of cast iron, the powers of the diameter and length were somewhat different. Mr. Hodgkinson found from a mean of experiments that a solid uniform pillar of cast iron, whose transverse section is one square inch, is destroyed by a weight of 98922 lbs., or 44·16 tons. Assuming this as a unit of measure, he gives the following formula (as representing his experiments), in which s is the strength or weight in lbs. that would crush the pillar, d the diameter, and l the length; viz. $s = 98922 \times d^{3\cdot55} \div l^{1\cdot7}$. This formula applies to pillars of which the lengths are twenty-five times the diameter and upwards, and which are perfectly flat at the ends. When the ends of a pillar are rounded, so that the load bears only on the middle fibres, the strength is greatly reduced. In pillars whose length is thirty times the diameter, or upwards, Mr. Hodgkinson found the strength of those with flat ends to be about three times greater than the strength of others of the same dimensions with round ends, the mean ratio being 3·167. In shorter pillars the ratio was not constant. The strength of a pillar is slightly increased by placing discs on the ends to increase the bearings.

Mr. Hodgkinson gives the following results of his experiments on the resistance to a crushing force of short pillars of some of the most common descriptions of wood, the force being applied in the direction of the fibres.

Description of Wood.	Strength per Square Inch, in lbs.
Alder	6831 to 6960
Ash	8683 — 9363
Bay	7518 — 7518
Beech	7733 — 9363
English Birch	3297 — 6402
Cedar	5674 — 5863
Red Deal	5748 — 6586
White Deal	6781 — 7293
Elder	7451 — 9973
Elm	10331
Fir (Spruce)	6499 — 6819
Mahogany	8198 — 8198
Oak (Quebec)	4231 — 5982
Oak (English)	6484 — 10058
Pine (Pitch)	6790 — 6790
Pine (Red)	5395 — 7518
Poplar	3107 — 5124
Plum (Dry)	8241 — 10493
Teak	12101
Walnut	6063 — 7227
Willow	2898 — 6128

The results in the first column were deduced in each case from experiments upon cylinders of wood turned to one inch diameter, and two inches long, flat at the ends. The wood was moderately dry. The second column gives the mean strength from similar specimens after being turned and kept dry in a warm place two months longer. The great difference in the strength frequently seen in the two columns shows strongly the effect of drying upon wood, and the great weakness of wet timber.

Mr. Tredgold found that cast iron is crushed by a weight of 93,000 lbs. upon a square inch, and will bear 15,300 lbs. without permanent alteration.

4. *Strength of Torsion.* — The resistance which bodies oppose to a force tending to wrench them asunder has frequently been made the subject of experiment. The following results, showing the comparative strength of various metals, as ascertained by resistance to torsion, is given by Mr. Rennie. For the law according to which the elasticity is evolved in the case of slender metallic wires or threads of fibrous substances, when the twisting force is less than is necessary to produce a permanent change of structure, we refer to the term TORSION.

Lead	1000
Tin	1438
Copper	4312
Brass	4688
Gun metal	5000
Swedish iron	9500
English iron	10125
Cast iron	10600
Blister steel	16688
Shear steel	17063
Cast steel	19562

Mr. Banks (*on the Power of Machines*) states, as the mean result of several experiments, that a bar of cast iron, one inch square, is wrenched asunder by a weight of 631 lbs. avoirdupois, applied at the extremity of a lever two feet in length. Other experiments on the force of torsion are given by G. Bevan (*Phil. Trans.* 1829), and Savart (*Annales de Chimie*, August, 1829).

For further information on this subject, in addition to the works already quoted, see Rondelet, *Art de Bâtir*; Girard, *Traité Analytique de la Résistance des Solides*; Tredgold, *Elementary Principles of Carpentry*, and *Practical Essay on the Strength of Cast Iron*; Banks, *Treatise on the Power of Machines*; Hodgkinson, *Transactions of the British Association*, vol. vi.; and *Phil. Trans.* 1840, &c.

STREPSI'PTERANS, *Strepsiptera*. (Gr. στρεπτος, *twisted*; πτερον, *a wing*.) The name given by Kirby to the order of insects which he discovered to possess rudimental elytra in the form of linear and spirally twisted scales.

STRETCHER. In Architecture, a brick or stone laid horizontally with its length in the direction of the face of a wall.

STRETCHING COURSE. In Architecture, a course in which the bricks or stones are laid horizontally with their lengths in the direction of the face of the wall. *See* HEADERS and HEADING COURSE.

STRE'TTO. (It. *narrow*.) In Music, a term indicating that the measure to which it is affixed is to be performed short and concise, hence quick. It is the opposite of *largo*.

STRI'ATE. (Lat. stria, *a groove*.) In Zoology, when a surface is painted or impressed with several narrow transverse streaks.

STRIGÆ. (Lat.) In Architecture, the flutings of a column.

STRIGI'DÆ. The name of the family of Nocturnal Raptores of which the owl (*Strix*) is the type.

STRING BOARD. In Architecture, a board with its face next the well-hole in a wooden staircase, which receives the ends of the steps.

STRING COURSE. In Architecture, a course running quite along the face of a building, the projecture whereof is small in proportion to its height.

STRO'BILE, or STRO'BILUS, is the fruit of the fir tree, to which the common name of cone is assigned. It may be defined to be a spike of very imperfect flowers subtended by bracts, which are woody, pressed close to each other, and in many cases consolidated.

STRO'MBUS. The name of a shell-fish in Pliny. This term was applied by Linnæus to a genus of the Vermes Testacea, characterized by the form of the shell, of which the aperture is much dilated, the lips expanding, and produced into a groove leaning to the left. The Mollusca to which this character is applicable form a group of Pectinibranchiate Gastropods in the system of Cuvier, which has been subdivided into the genera *Strombus* proper, *Pterocera*, Lam., &c.

STRO'NGYLUS. A genus of intestinal worms in Rudolphi's classification, characterized by having a cylindrical body, the anal extremity of which, in the male, is surrounded by a kind of pouch of a varied shape, from which is protruded a small filament or spiculum, probably subservient to generation. The mouth is orbicular, sometimes armed with spines, as in the *Strongylus armatus*, which infests the mesenteric arteries of the horse and ass, producing aneurisms; sometimes the mouth is surrounded by tubercles or papillæ, as in the *Strongylus gigas*, which is sometimes found in the kidney of the human subject.

STRO'NTIA. An earth contained in a mineral, generally of a pale green tint and radiated crystalline texture, found at Strontian in Argyleshire. It is a carbonate of strontia. Strontia is the oxide of a metallic base, the properties of which are very imperfectly known, called strontium; the equivalent of strontia, or oxide of strontium (composed of 44 strontium and 8 oxygen), is 52. It has a caustic taste, an alkaline reaction, and a degree of solubility in water intermediate between lime and baryta. The salts of strontia are generally obtained by dissolving the natural or artificial carbonate in the acids; those which are soluble give the flame of burning bodies a fine rose red colour: the nitrate of strontia is used for this purpose, and with beautiful effect, in theatrical exhibitions and fire-works. The sulphate of strontia is found native: it is an insoluble white powder when artificially prepared. Some of its native varieties have a pale blue tint, whence the term *cœlestine*. A colourless prismatic crystalline variety, of great beauty, is found associated with the native sulphur of Sicily.

STRO'NTIANITE. Native carbonate of strontia.

STRO'PHE. (Gr. στροφή, *a turning*.) A division of a Greek choral ode answering to a stanza. The name is derived from στρέφειν, *to turn*, because the singers turned in one direction while they recited that portion of the poem; they then turned round and sung the next portion, which was of exactly the same length and metre as the preceding, and was termed the antistrophe (ἀντι-

στροφή, from ἀντί, *opposite*). These were sometimes followed by another strophe and antistrophe, sometimes by a single stanza called the epode (ἐπῳδός).

STROPHI'OLÆ. In Botany, synonym of *Caruncula*, which see.

STROPHU'LUS. (Lat.) The *red gum*; an eruption peculiar to infants.

STRUMA. (Lat.) In Anatomy, an enlarged gland.

STRUMA. In Botany, a swelling that is present in some leaves at the extremity of the petiole, where it is connected to the lamina; as in *Mimosa sensitiva*. The term also used in describing mosses to denote a dilatation or swelling that is at times present upon one side of the base of the theca.

STRUT. In Architecture, a piece of timber obliquely placed from a king or queen post to support a rafter. It is sometimes called a brace. *See* ROOF.

STRUTHIO'NIDÆ. (Struthio, *an ostrich*.) The name of a family of terrestrial birds, incapable of flight, with very short or rudimental wings, and long and strong legs; including the ostrich and other congeneric species which constitute the order *Cursores* of Kirby, and the family *Brevipennes* in the system of Cuvier.

STRY'CHNIA. A poisonous vegetable alkaloid, discovered in 1818 by Pelleter and Caventou in the seed of the *Strychnus ignatia* and *Nux vomica*, and also in the upas poison. It is almost insoluble in water, but very soluble in boiling alcohol, from which it is deposited by careful evaporation in small white crystals. It is so virulently poisonous that half a grain blown into the throat of a rabbit occasioned death in five minutes; its operation is accompanied by lock-jaw and by other tetanic affections. The chemical equivalent of strychnia is about 238. It probably consists of 30 atoms of carbon, 16 hydrogen, 3 oxygen, and 1 nitrogen.

STU'BBLE. The root ends of stalks of corn, left in the field standing as they grew after the corn has been reaped by the sickle or scythe. In some parts of the country only a small portion of the straw is cut off with the ears of corn, and the stubble in that case is a foot or eighteen inches in length; but in others the corn is cut as close to the surface as possible, in which case the stubble is quite short. In general long stubble is a symptom of bad farming, because a quantity of straw is in this case left waste in the field, which might have been carried home and rotted into manure.

STU'CCO. (Ital.) In Architecture, a term applied to many sorts of calcareous cements. The sense in which it is most commonly used in this country is to denote the third coat of three-coat plaster, consisting of fine lime and sand. The better sort is hand-floated twice and well trowelled. There is a species called bastard stucco, in which a small portion of hair is used. (*See* FINISHING.) Rough stucco is merely floated and brushed with water, but the best is trowelled stucco.

STUDDING SAILS, called also Steering Sails, are narrow sails set temporarily at the outer edges of the square sails.

STUFA. (Ital.) A jet of steam issuing from a fissure in the earth: these jets are not uncommon in volcanic districts.

STUFF. A Commercial term, applied to various woven fabrics; it especially signifies a light woollen cloth formerly much used for curtains and bed furniture.

STU'RGEON. (Lat. sturio, from the German stoer, *a sturgeon*.) The type of a genus of Cartilaginous fishes, with free gills, having the body more or less covered with bony plates in longitudinal rows. The mouth is placed beneath the snout, is small and edentulous; but is protractile. Soft feelers or cirri are attached beneath the snout. The bodies of the vertebræ retain the primitive condition of an undivided gelatinous cord. The sturgeons ascend the larger rivers of Europe in great abundance, and are the objects of important fisheries. The flesh of most of the species is wholesome and agreeable food; their ova are converted into caviar, and their air-bladder affords the finest isinglass.

The sturgeon which is occasionally captured on our east coast is the *Accipenser sturio* of Linnæus. *See* ACCIPENSER.

STURIONIANS, *Sturionii*. (Lat. sturio, *a sturgeon*.) The name of the family of Cartilaginous fishes of which the sturgeon is the type.

STY. A little boil or tumour projecting from the edge of the eyelid.

STYLAGA'LMAIC. (Gr. στυλος, *a column*, and αγαλμα, *an ornament*.) In Architecture, a term used to denote figures which perform the office of columns. *See* CARYATIDES.

STYLE. (Lat. stylus, or stilus.) A kind of pencil made use of by the Romans for writing on waxed tablets. It was made of brass or iron, with one end sharp for writing, and the other blunt and smooth to make erasures with; hence to *turn the style* is a phrase used by ancient writers, signifying to make corrections.

In Literature, the word style may be defined to mean the distinctive manner of writing which belongs to each author, and also to each body of writers, allied as belonging to the same school, country, or age. It is that which, to use the expression of Dryden, individuates each writer from all others. The style of an author is made up of various minute particulars, which it is extremely difficult to describe, but each of which adds something to the aggregate of qualities which belong to him. Collocation of words, turn of sentences, syntax, rhythm; the relation, abundance, and the character of his usual figures and metaphors; the usual order in which thoughts succeed each other; the logical form in which conclusions are generally deduced from their premises; the particular qualities most insisted on in description; amplification and conciseness, clearness and obscurity, directness and indirectness, exhaustion, suggestion, suppression; — all these are features of style, in the largest sense of the expression, in which it seems to comprehend all peculiarities belonging to the manner in which thought is communicated from the writer to the reader. Excellence of style, particularly of the rhetorical parts of style, was more cultivated by the ancients than the moderns; and less, perhaps, at the present day, than at any former period since the English language began to be written in prose with correctness and elegance. Since the period when Bolingbroke, Junius, Johnson, Gibbon, and Burke became established as models, a certain superficial sameness of style, wanting in the roughness and vulgarity, but also in the force and individuality of old English composition, seems to prevail to such an extent as to render modern writing extremely monotonous and artificial. But it should never be forgotten that whatever quality may command a temporary popularity, no work, either in poetry or prose, has ever permanently maintained its hold on public admiration without excellence of style.

STYLE, in the Calendar, is a manner of reckoning time. The reformation of the calendar by Julius Cæsar consisted chiefly in restoring the equinox to its proper place in the month of March. This reformation took place in A. U. C. 707, which year was made to consist of fourteen months, in order to fill up the deficiency which had been produced by the former method of computing, and was styled the "year of confusion." By the Julian calendar an intercalary day was added to every fourth year (leap year). In consequence of this erroneous intercalation, the equinox receded a day in about 130 years; and, in the beginning of the sixteenth century, the vernal equinox fell on the 10th instead of the 21st of March. The calendar was reformed by Gregory XIII. in 1577. By this reformation ten days were dropped in the year 1582, the 15th of March being reckoned immediately after the 4th; and it was arranged that every 100th year (which by the former calendar was a leap year) should be a common year, except the fourth, *i.e.* 1600 remained a leap year; but 1700, 1800, were common years; and 1900 will be a common year likewise, after which the cycle of four centuries will again commence. The Gregorian calendar was immediately adopted in Catholic countries; but by Protestant nations the old style was for a long time continued. England adopted the *New Style* in 1752 by statute, after debates in parliament, of which a curious notice will be found in *Lord Chesterfield's Letters*. Previously to this time, dates according to the old style are frequently denoted by the initials O. S.; or thus, $\left.\begin{matrix}10\text{th}\\22\text{d}\end{matrix}\right\}$ of January, 1750, the upper line denoting the old, and the latter the new style. This mode of dating will still be found in the despatches and public papers of Russia and Greece, which are the only European states in which the Julian year is still in use. The time of the two styles now varies thirteen days. For further information on this subject, see CALENDAR.

STYLE, in Dialling, is the gnomon which projects the shadow on the plane of the dial. *See* DIAL.

STYLE, in Botany, is that elongation of the ovarium which supports the stigma. It is an extension of the midrib of the carpellary leaf, or is formed by the rolling up of the attenuated extremity of the latter.

STYLE. In the Fine Arts, the mode in which an artist forms and expresses his ideas on and of a given subject. It is the form and character that he gives to the expression of his ideas, according to his particular faculties and powers. Style may be almost considered as the refinement of *manner* (*see* MANNER): it is a characteristic essence by which we distinguish the works of one master from another. From literature this word has passed into the theoretic language of the fine arts; and as in that we hear of the *sublime*, *brilliant*, *agreeable*, *historic*, *regular*, *natural*, *confused*, and other styles, so we have almost the same epithets applied to styles of art. Indeed this is not wonderful, since the principles of taste, in both the one and the other, are founded in nature; and it is a well-known saying, that poetry is a speaking picture. This word is improperly used as applied to colouring and harmony of tints: we speak of the style of a design, of a composition, of draperies, &c.; but not of the style of colouring, but rather the *method*

or *manner* of colouring. The definition of this word by Sir Joshua Reynolds is as follows: — "Style in painting is the same as in writing, — a power over materials, whether words or colours, by which conceptions or sentiments are conveyed." But we can scarcely consider this definition sufficiently general.

STY'LITE. (Gr. *στυλος, a column.*) The title given to a peculiar class of anchorites from the places on which they took up their solitary abodes, being the tops of various columns in Syria and Egypt. This strange method of devotion took its rise in the second century, and continued to be practised by many individuals for a great length of time. The most famous among them was one St. Simeon, in the 5th century, who is said to have lived thirty-seven years upon various columns of considerable height in the neighbourhood of Antioch.

STYLO. Names compounded of this word apply to the muscles attached to the styloid process of the temporal bone.

STY'LOBATE. (Gr. *στυλος, a column*, and *βασις, a base.*) In Architecture, a term signifying the uninterrupted base below a range of columns.

STY'PTICS (Gr. *στυφω, I restrain*), in Medicine and Surgery, are remedies used for checking a flow of blood.

STYRAX. *See* STORAX.

STYX. (Gr. Στυξ.) In Mythology, a nymph: the daughter, according to Hesiod, of Oceanus and Thetis; but other mythologists relate the genealogy differently. She dwelt in a rock palace in the infernal regions, from whence one of the infernal rivers burst forth. This river, Styx, was one of the ten arms or branches of Oceanus. The gods of Olympus swore by the water of Styx; and a deity who took this oath in vain was banished from the heavenly mansions for ten years, to endure various torments. The river Styx has been sought for in various places; but the most remarkable stream of the name was in Arcadia. It forms a terrific waterfall.

SU'BALTERN. (Lat. sub, *under*, and alter, *other.*) Literally an inferior officer, but generally applied to all officers under the rank of captain.

SUBBRA'CHIANS, *Subbrachia.* (Lat. sub, and brachium, *the arm.*) The name of the order of Malacopterygious fishes comprising those which have the ventral fins situated either immediately beneath and between, or a little in front or behind the pectoral fins.

SUBCLA'VIAN. An Anatomical term applied to vessels, nerves, &c. under the shoulder or armpit.

SUB-CO'NTRARY SECTION. In Geometry, if an oblique cone on a circular base be cut by a plane not parallel to the base, but inclined to the axis, so that the section is a circle, then the section is said to be *sub-contrary.* The part of the cone thus cut off is similar to the whole cone; the plane of the section and the base of the cone being equally inclined to the axis, but the inclination being in opposite directions.

SUBDO'MINANT. (Lat. sub, *under*, and dominans, *governing.*) In Music, that note which is a fifth below the key note. It is a species of governing note, inasmuch as it requires the tonic to be heard after it in the plagal cadence. In the regular ascending scale of seven notes it is the fourth; the term, however, has its origin from its relation to the tonic as the fifth below.

SUBDU'PLICATE RATIO. In Arithmetic and Algebra, the subduplicate ratio of two numbers is the ratio of their square roots. Thus, the subduplicate ratio of the numbers 9 and 16 is the ratio of 3 to 4; and of the numbers a and b, it is the ratio of $\sqrt{a}$ to $\sqrt{b}$.

SU'BERIC ACID. (Lat. suber, *cork.*) An acid substance into which cork is converted by the long-continued action of nitric acid.

SU'BERIN. A name given by Chevreul to the cellular tissue of cork after the various soluble matters have been removed by the action of water and alcohol.

SU'BITO. (It. *suddenly.*) In Music, a term of direction; as *volti subito*, turn (the leaf) quickly.

SUBJECT. (Lat. subjicio, *I throw under.*) In the Fine Arts, that which it is the object and aim of the artist to express.

SU'BJECTIVE and OBJECTIVE. Terms expressing the distinction which in analyzing every intellectual act we necessarily make between ourselves, the conscious *subject*, and that of which we are conscious, the *object.* "I know," and "something is known by me," are convertible propositions; every act of the soul which is not thus resolvable belongs to the emotive part of our nature, as distinguished from the intelligent and percipient. For the distinction between subject and object, all-important in intellectual philosophy, and the neglect of which has been the cause of infinite confusion and perplexity, we are indebted to the schoolmen; from whom it was derived, through Wolf and Leibnitz, by Kant and the modern German philosophers.

SUBJECT OF A PROPOSITION, in Logic, is the term of which the other is affirmed or denied. *See* TERM, PROPOSITION, LOGIC.

SUBLAPSA'RIANS or INFRALAPSARIANS. In Ecclesiastical History. The greater number of the divines of the reformed or Calvinist churches have held that God *permitted* the fall of Adam, without positively predetermining it; a doctrine which has been termed sublapsarian, in opposition to the high Calvinistic or supralapsarian view. (*Mosheim*, cent. xvii. sect. 2.) *See* SUPRALAPSARIANS.

SUBLIMA'TION. (Lat. sublimatio.) A process by which solids are by the aid of heat converted into vapour, which is again condensed, and often in the crystalline form. This operation is frequently resorted to for the purpose of purifying various chemical products, and separating them from substances which are less volatile.

SUBLI'ME. (Lat. sublimis.) In the Fine Arts, high or exalted in style. That which in art is raised above the higher standard of nature or its prototypes. Sublimity is incompatible with our ideas of elegance, grace, or any of the other sources of beauty, though these may all enter into an object wherein those and many other qualities may be combined with sublimity. They have been, however, not unfrequently considered as some of the sources of the sublime. The nod of Jupiter, in the hands of such a master as Homer, is an indication of sublimity; but when Longinus tells us, that, as applied to literature, the constituent ingredients of sublimity are boldness in thought, the pathetic, proper application of figures, use of tropes and beautiful expressions, and, last, musical structure and sounds, we are inclined to think he had very indistinct notions of it himself. We cannot better exemplify the meaning of this term than by referring the reader to the works of Michael Angelo in the Sistine Chapel, wherein, as Fuseli has truly said, "His line is uniformly grand; character and beauty were admitted only as far as they could be made subservient to grandeur. The child, the female, meanness, deformity, were by him indiscriminately stamped with grandeur. A beggar rose from his hand the patriarch of poverty; his infants teem with the man, his men are giants." The *terribile via*, hinted at by Agostino Caracci, is indeed the sublime.

SUBME'DIANT. (Lat. sub, *under*, and medius, *middle.*) In Music, the middle note between the tonic and subdominant descending. It is the greater sixth in the major scale, and the lesser sixth in the minor scale.

SUBMU'LTIPLE, in Arithmetic and Geometry, is the same with *aliquot part* or *measure;* or it is such a part of a quantity as can be expressed by a whole number, as a third, a fourth, &c.

SUBNO'RMAL, in Geometry, is that part of the axis of a curve line which is intercepted between the ordinate and the normal. If y be the ordinate, and x the absciss of any curve, the expression for the subnormal is $y\,\frac{dy}{dx}$. The subnormal is always a third proportional to the subtangent and the ordinate. *See* SUBTANTENT.

SUBO'RDINARY. In Heraldry. According to some writers on this imaginary science, an ordinary, when it comprises less than one fifth of the whole shield, is termed a subordinary.

SUBORNA'TION. (Lat. sub and orno, *I provide, furnish, procure;* a meaning not classical.) Subornation of perjury, in Law, is the procuring a man to take a false oath amounting to perjury. The offence of subornation is not complete unless the oath be taken, so as to bring the offender within the stat. 2 G. 2. c. 25.; but it is a misdemeanor to attempt to procure false testimony.

SUBPŒ'NA. In Law, a writ of which there are several sorts. *Subpœna ad testificandum* is the common progress, both in equity and in the courts of common law, to compel the attendance of a witness. *Subpœna duces tecum* is a writ of the same nature with the former, with a clause requiring the witness to bring with him and produce books and papers. An action of damages lies against parties disobeying this writ.

SUB-SE'MITONE. In Music, the leading note or sharp seventh of the scale. It is a term more used by the German than by other writers.

SU'BSIDY. (Lat. subsidium, *assistance.*) In Politics, pecuniary aid granted by one government to another in pursuance of a treaty. The grants of public money made to the sovereign, or taxes imposed in this country, were called subsidies.

SU'BSTANTIVE COLOURS, are those which, in the process of dyeing, remain fixed or permanent without the intervention of other substances; they are opposed to *adjective colours*, which require to be fixed by certain *intermedes*, or substances which have a joint affinity for the colouring matter and the material to be dyed. *See* DYEING and MORDANT.

SU'BSTANTIVE, or NOUN SUBSTANTIVE. In Grammar, that part of speech which denotes a *substance* or *subject*, as distinguished from an *attribute* or *predicate*. *See* GRAMMAR.

SUBSTITU'TION, is defined by writers on the Civil Law to be the designation of a second, third, or other heir, to enjoy, in default of a former heir, or after him. Taken in this general sense, it includes all those modes of disposition which are expressed in our law by the

terms *entail*, *remainder*, *executory devise*, &c. Substitutions were of two classes: 1. *Vulgar* or common, by which a testator named a second devisee to receive the succession, if the first were unable or unwilling to do so; 2. Fidei-commissary, in which the second devisee was named to receive the succession *after* the first. *See* FIDEI-COMMISSUM.

SUBSTITUTION, in the language of Algebra, signifies the replacing of one quantity by another which is equal to it, but differently expressed.

SUBSTITUTION, CHORD OF. In Music, a name given to the chords of the ninth major and minor.

SUBSTRA'TUM. A stratum lying under another. The term *subsoil* is generally applied to the matters which intervene between the surface soils and the rocks on which they rest; thus clay is the common substratum or subsoil of gravel.

SU'BSTYLE, in Dialling, is the straight line formed by the intersection of the face of the dial with the perpendicular plane which passes through the gnomon. *See* DIAL.

SUBTA'NGENT, in Geometry, is the part of the axis of a curve intercepted between the tangent and the ordinate. The general expression for the subtangent of any curve whose equation is $y = F\,x$ (y the ordinate being a function of x the absciss) is $y\dfrac{dx}{dy}$.

SUBTE'NSE. (Lat. sub and tensus.) A term sometimes used in Trigonometry to denote the chord of an arc. *See* CHORD.

SUBTRA'CTION. (Lat. subtraho, *I draw away*.) In Arithmetic, the taking of one number or quantity from another in order to find their difference. The operation is precisely the reverse of addition.

SUBU'LICORNS, *Subulicornes*. (Lat. subula, *an awl*; cornu, *a horn*.) The name of a family of Neuropterous insects, including those which have awl-shaped antennæ.

SUBU'LIPALPS, *Subulipalpi*. (Lat. subula, and palpus, *a feeler*.) The name of a section of Caraboid beetles, including those which have the exterior palps or feelers awl-shaped.

SUCCEDA'NEUM. A medicine or remedy substituted for another.

SUCCE'SSION, APOSTO'LICAL. In Theology. By these words is meant the uninterrupted succession of priests in the church by regular ordination, from the first commission given by our Saviour to the Apostles, and recorded in the Gospels, down to the present day. And the doctrine of "the apostolical succession," as it is popularly called, means the belief that the clergy so regularly ordained have a commission from God to preach the gospel, administer the sacraments, and guide the church; that through their ministration only we can derive the grace which is communicated by the sacraments. It follows, of course, that those sects of Christians which have no regular succession (having seceded from Romanism without retaining ministers regularly ordained, or having subsequently interrupted the succession, that is, all Protestant bodies, except the church of England) have, properly speaking, neither church nor sacraments, since they possess no apostolical authority.

This doctrine was, by admission on all hands, of very great antiquity in the church; but whether that antiquity is primitive or not, is matter of discussion at the present day. The arguments from Scripture cannot alone be relied upon by either party. As to the historical part of the question, those Epistles of Ignatius which the learned have in the most part agreed to regard as genuine (commonly called the Greater), are much referred to by the maintainers of the doctrine in support of it. They do not, indeed, declare it in express terms; but the strict and repeated injunctions to honour and obey the bishop and presbytery, together with some insulated expressions (such as, "If a man be not within the altar, he faileth of the bread of God," &c.), have been thought important in the controversy; and, as Mr. Keble observes, "the discovery of those remains probably lent considerable force to the course of opinions among the clergy of England in favour of the doctrine in the 17th century."

At the Reformation it was almost entirely lost sight of; and that the succession was actually preserved in England is rather owing (humanly speaking) to political causes than to any deliberate intention on the part of the then leaders of the church. In fact, the Romanists contest the validity of English ordinations, partly on the ground that the succession was actually interrupted at the accession of Elizabeth; but there is no need to discuss an historical question on which there seems to be no substantial doubt whatever. The church of England does not affirm the doctrine in her articles; and the language of art. 19., although not excluding it, is plainly not such as would have been used by framers who wished to inculcate it. Many expressions of her services, borrowed as they are from ancient liturgies, more or less distinctly point towards it. The first school of Anglican divines did not rely on it in their controversy with Puritanism. They rather rested their argument on the fact, that the church *had* in early times appointed the episcopal government and regular ordination, and that it could not, therefore, be wise or prudent to swerve from it. It was at this point that Hooker took up the subject. Whether he actually held the tenet or no, has been much controverted. His recent editor (Mr. Keble) contends that he did; but, at the same time, admits that there is a marked difference between his language and that of the succeeding school of Laud, Hammond, and Leslie. (Preface to *Hooker*, p. lxxvii.) Under that school, it became the rallying point of high churchmen, and was zealously maintained by the divines of that section of the church down to and long after the Revolution. But since that time, without being renounced, it had certainly long ceased to be brought prominently forward in ecclesiastical controversy, until within the last seven or eight years.

In fact, the opposite ground had been constantly taken by ordinary Protestant reasoners, both in and out of this country, in their contests with the church of Rome. Chillingworth, as is well known, argues against the Romanist tenet, that "succession is a certain and perpetual mark of the true church," by maintaining that it is impossible to prove it; that is, that it is impossible that any individual can feel certain that *his* orders were derived by regular succession from the Apostles. If we assume, with the Romanist, *à priori*, that the church must have regular succession because of Christ's promise to it, then there is no room for such doubts; but if we are endeavouring to insist on the fact of succession as a test of the truth of a church, then it cannot be denied that this argument presents difficulties not easily surmounted.

SUCCESSION, LAW OF. In Political Economy, the law or rule according to which the succession to the property of deceased individuals is regulated. Generally speaking, this law obtains only in cases where a deceased party has died intestate, or in cases where the power of bequeathing property by will is limited by the legislature. It is plain that in cases of intestacy, where the deceased either leaves a number of descendants, or where he leaves no direct descendants, the law, in order to prevent endless disputes and litigation, must interfere to regulate the succession to the property; and it will necessarily follow that the succession will be determined in different countries by local circumstances, depending partly on the peculiar state and institutions of each country, and on the views entertained by its legislators of what is just and proper, and most conducive to the public advantage. Hence it is to no purpose in a matter of this kind to look for any general or fixed principles. The succession to the property of those dying intestate, and the power of bequeathing property by will or testament, depend wholly on the rules and regulations enacted in each country; and these necessarily vary with the varying circumstances of different countries and conditions of society.

In most countries a preference has been given, in regulating the succession to property vacant by intestacy, and in defining the power to leave property by will, in favour of male heirs; and in some countries, and especially in modern times, a marked predilection has been shown in favour of the eldest son, or, as it is usually termed, in favour of the *right of primogeniture*. Among the Jews, the eldest son was entitled to a double share of the paternal inheritance; but among the Greeks, Romans, and our Saxon ancestors, all inheritances, whether consisting of land or moveables, were equally divided, in some cases among all the male children, and in others among all the children, whether male or female. The growth of the feudal system appears, however, to have put an end to this rule of inheritance in most European nations. When titles of nobility were created, it was necessary to limit their descent to the eldest son; and it was also necessary that the estate required to maintain the dignity of the possessor of the title should descend according to the same rule of primogeniture. And even when estates were not held by noble proprietors, various inconveniences were found to result from their partition, in the division of military services; the number of infant tenants incapable of performing any kind of duty; and, more than all the rest (though its importance was the last to be perceived), the injurious influence of the system of equal partition in occasioning the too great subdivision of the land, in emancipating the younger sons from the control of their parents, in tempting them to remain at home and to indulge in the pleasures and idleness of a country life, and lastly, in overspreading the country with a proud and a beggarly gentry. In consequence, the old rule of succession to landed property was changed in most countries; and in England, except in Kent and a few other places, when a person dies intestate his estate descends entire to his eldest son. And it will be afterwards seen, notwithstanding the statements of Adam

Smith and others to the contrary, that this rule, though not without its disadvantages, is, on the whole, the best that can be devised.

Females being incapable of performing any personal feudal service, it is the common rule, when a person seised of an estate dies intestate leaving only daughters, that they should succeed as co-heiresses. Such is the law of England; and, when thus limited, little harm can ensue from the subdivision that is thus occasioned.

It has, speaking generally, been the usual practice in cases of intestacy to divide the money or other moveable property in equal portions among the children or kinsmen of the deceased, without respect to sex or seniority. This, however, though a general, is by no means to be regarded as a constant rule. Thus, in the case of the Jews, daughters were excluded from all participation in the inheritance, and, apparently, were left to depend on the bounty of their father's heirs. (Michaelis, *Law of Moses*, i. 420.) In Athens, also, daughters inherited nothing when there were sons alive; and when there was no son, and a daughter succeeded to the inheritance, she was bound to marry her nearest relation, so that the property might not be taken out of the family. (Michaelis, *ubi suprà.*) In Rome, however, all sorts of property were divided equally between sons and daughters. And as the inconveniences found to result in modern times from the splitting of landed property do not follow at all, or in anything like the same degree, from the subdivision of moveable property, it is the practice in this and most modern countries to admit females of the same propinquity to share in the succession to such property, when left intestate, equally with males, excluding all preference on account of primogeniture.

These notices, brief and imperfect as they necessarily are, will probably be sufficient to give the reader a general idea of the rules that have been most commonly followed in regulating the succession to property in cases of intestacy, or where there is no power to bequeath property by will or testament. Inasmuch, however, as this power exists to a greater or less extent in most civilized countries, we shall now proceed shortly to state some of the more important principles and limitations that either have been or should be attended to in the construction of such documents.

Bequeathing of Property by Will.—The power of bequeathing property by will or testament (the *libera testamenti factio*) is not usually recognized in the earlier stages of society. A man's property is then, for the most part, divided in equal shares among his children, who succeed to it as matter of right; and in their default it is inherited by his surviving relations, or nearest of kin. But experience begins at length to manifest the inconveniences resulting from the enforcement of this strict rule of succession, and power is, in consequence, given to persons possessed of property to make testaments, or to dispose of a part at least of their personal or real estate by will. At first, however, this power is usually confined within very narrow limits, being in general restricted to the making of alterations in the shares falling to the children or kinsmen of the testator; that is, to the increasing of the portion of some to the diminution of that of others. Thus, in Athens, there was no power to devise property from the natural heirs previously to the age of Solon; and that legislator confined the privilege to those who died without leaving issue. In Rome, three centuries elapsed before a citizen could dispose of his property by a deed *mortis causa*, except in an assembly of the people; and in that case his will, as Montesquieu has remarked, was not really the act of a private individual, but of the legislature. "With us in England, till modern times, a man could only dispose of one third of his moveables from his wife and children; and in general no will was permitted of lands till the reign of Henry VIII., and then only of a certain portion: for it was not till after the Restoration that the power of devising real property became so universal as at present." (*Blackstone*, book ii. cap. i.) In Scotland, down to a comparatively recent period, almost all landed property was inalienable from the lineal heir.

Not only, however, is the power of testators usually augmented as society advances, but in some countries they are permitted to exercise a nearly absolute control over the disposal of their property, and even to bequeath the whole, or the greater part of it, to strangers, to the exclusion of their children and relations, as is substantially the case at this moment in England. This, however, is an extension of the power of bequeathing, as to the policy of which much difference of opinion is entertained. It is contended that no one who has any property to dispose of should be allowed to throw his children destitute upon society; that the fear of total disinheritance should not be rendered an instrument of tyranny in the hand of fathers; and that before allowing a man to leave any portion of his fortune to strangers, he should be compelled to make an adequate provision for the individuals he has been the means of bringing into the world, and to whom, independently altogether of any considerations of personal merit or demerit, he is under the most sacred obligations. But though it must be owned that this is a question of considerable difficulty and nicety, and with respect to which it does not seem possible to come to any conclusion that will not be liable to objections, yet, on the whole, it would seem that the reasoning of those who argue in favour of the unlimited power of bequeathing to strangers is the most satisfactory and convincing; or if any restriction be laid on this, it would appear to be enough to enact that parents possessed of property should be obliged to appropriate a portion thereof sufficient to bring up and educate their children till they come to maturity, or be in a condition to provide for themselves, when all compulsory obligations on the part of the parents should cease. None but the strongest possible reasons can ever justify a legislature in giving their sanction to any measure having a tendency to weaken the spirit of industry and economy in the people. It is plain, however, that if it interfere to regulate the disposal of property, it must unavoidably do this: if it be enacted that how undutifully soever a man's children or relations may have behaved, they shall notwithstanding be entitled to the whole or a certain proportion of his fortune, this will, in the first place, render every one less anxious about the accumulation of that wealth which he is not to be permitted to dispose of at pleasure than he would otherwise be; and, in the second place, the securing of a certain provision to children, independently of their conduct, must in so far render them independent of their parents, and weaken that parental authority, which, though occasionally abused, is yet, in the vast majority of instances, exercised in the mildest and most indulgent manner, and with the best effect. The more, therefore, that this subject is inquired into, the more, we apprehend, it will be found that it is always the safest policy to abstain as much as possible from making the relations of private life the object of legislative enactments. The humanity of the law is but a sorry substitute for parental affection. If children be ordinarily well-behaved; if they be not extremely deficient either in filial affection or common prudence, we have, in the principles and instincts inherent in our nature, a sufficient security that but few parents will be found disposed to leave their property to others to their exclusion. The interference of the legislature in their behalf appears therefore to be, speaking generally, quite unnecessary. In countries like England and Holland, in which the greatest latitude is given to the power of bequeathing, the instances are extremely rare in which an affectionate and dutiful family have suffered from the circumstance of their father being permitted to leave his fortune to strangers; and it would be most impolitic to attempt to obviate an evil of such rare occurrence by exempting children from the constant influence of a salutary check on their vicious propensities, and compelling a man to bestow on profligacy, extravagance, and idleness, that property which is at once the fruit and the appropriate reward of virtue, economy, and industry.

The advantages resulting from the unrestrained power of bequeathing property by will are so striking as hardly to require to be pointed out. Perhaps, however, we may be excused for laying the following passage, from the valuable though little known work of M. Luzac, *De la Richesse de la Hollande*, before the reader. It strongly corroborates what has now been stated. "La liberté de tester, celle de disposer à volonté de ses biens, par un acte de dernière volonté peut encore être mise au nombre des causes, qui ont contribué à animer l'industrie des habitans. Quelque indifférent que l'on soit sur le partage des biens que l'on laisse en mourant, l'idée de pouvoir en faire jouir ceux qu'on veut en gratifier, est sûrement un aiguillon qui doit exciter au travail, ou du moins prévenir qu'on se dégoûte d'accumuler des richesses. Pourquoi travaillerai-je à augmenter ma fortune si je suis obligé de la laisser à ceux qui ne m'en sauront aucun gré, et qui ne la meriteront pas? *La liberté de disposer librement de ses biens par testament, est peut-être la principale cause que les fortunes des particuliers sont plus considérables en Hollande que par tout ailleurs.*" (i. 304.)

Entails.—The recognition of the right to bequeath property to any particular heir has, in several countries, been followed by an acknowledgment of the right of the proprietor of an estate to name an indefinite series of heirs, and to prescribe the conditions on which they shall be entitled to hold the property. This right is founded by lawyers on the maxim of the civil law, that every one has the absolute disposal of his own property: *unusquisque est rei suæ moderator et arbiter*. This, however, is not a natural but a civil right; and it is not to be judged of by referring to abstract or imaginary principles, but by its practical operation and real influence over the condition and interests of society. To enter fully into an examination of the advantages and disadvantages incident to the practice of entailing, would far exceed the narrow limits within which an article of this description must be confined; but we may, notwithstanding, glance at one

or two of the principal topics that should be attended to in forming a correct conclusion as to the influence of entails.

In the first place, it is alleged in their favour that they stimulate exertion and economy; that they hold out to honest industry and ambition the strongest and safest excitement, in the prospect of founding an imperishable name and a powerful family, and of being remembered and venerated by endless generations as their chief and benefactor; and, in the second place, it is said that entails form the only solid bulwark of a respectable aristocracy, and prevent generations from being ruined by the folly or misfortunes of an individual.

Now, it is not to be denied that the prospect of founding a powerful family, and of securing property, accumulated during a course of laborious and successful exertion and economy, from the risk of being squandered by the inconsiderate projects or extravagance of any future individual, must act as a very powerful spur to the industry and ambition of the *original founder* of a family. But here the beneficial influence of the system stops; its operation on the subsequent holders of the property is entirely different. An heir of entail is in a great measure emancipated from the influence of parental authority; his chance of succeeding to the property of his ancestors does not depend on the circumstance of his having deserved it, of his being industrious or idle, dissipated or sober. The succession to entailed estates is not regulated by the principle of *detur digniori.* Their occupiers have no power to change the established order of succession; they cannot exclude the worst to make room for the best of their descendants, but must submit to see the properties of which they are in possession descend, as, in fact, they not unfrequently do, to the most worthless and undutiful of their children or relations. Granting, therefore, that the institution of entails has a tendency, as it undoubtedly has, to make *one generation* active, frugal, and industrious, it is clear to demonstration that it must exempt every succeeding generation, that is, every succeeding heir of entail, from feeling the full force of some of the most powerful motives to such conduct. A system of entail makes the succession to property depend, not on the good or bad conduct of the individual, but on the terms of a deed written a couple of centuries, perhaps, before he was in existence. Its effect is, therefore, to substitute a species of fatalism in the place of an enlightened discrimination, to throw property indifferently into the hands of the undeserving and the deserving; and it is plainly impossible it can do this without weakening the motives which stimulate men to act the part of good citizens, and strengthening those of an opposite description. When, therefore, we refer, as we ought, to the decisive criterion of public utility, it is immediately seen that the industry of *one* generation is not to be purchased by the idleness of *all* that are to come after it; and that it is not much less injurious to allow an individual to appoint his remotest heirs, than it would be to deprive him of the power of nominating his immediate successors.

As to the second point, there can be no doubt that a system of entail affords the best attainable security for the permanence of property in particular families; and as individuals possessed of property act, generally speaking, with more independence, and are less liable to be biassed by purely selfish considerations than those who are comparatively poor, it would seem that the privilege of executing a perpetual entail of a certain amount of property might, with propriety, be allowed to noble families. Indeed, we are disposed to think that in the case of such families it would be advantageous to carry this principle a good deal farther; and that no individual should be advanced to the peerage unless he were able to establish a *majorat*, or to entail such an extent of landed property on the heirs of the title as might be sufficient to secure them, supposing they acted with ordinary prudence, from falling into a state of poverty, and becoming mere dependents on the crown. But though the power of entailing were conceded to noble families vested with the prerogative of hereditary legislation, it might be confined within certain limits, and made to vary with the entailer's rank in the peerage. Neither is there the shadow of a reason, on political grounds, for conceding this power to others. A system of perpetual entail is, in a general point of view, certainly injurious; and though constitutional considerations may require the privilege to be granted, under proper modifications, to a particular class, they can never require that it should be granted to all. It is not possible to interfere to protect the families of the commons from the casualties to which they are subject, by sanctioning a system of perpetual entail, without producing mischievous results. It is the duty of government to adopt such regulations as may most effectually call forth industry and economy among all classes of its subjects; but it is no part of its duty to inquire whether the frugality of those on the box, and the extravagance of those in the coach, bid fair to make them change places; and still less to attempt to prevent it by throwing artificial ramparts round the property of the latter.

In Scotland the practice of entailing has been carried to a very great extent, and in some counties hardly an acre of land is now to be met with that is not burdened with the fetters of a perpetual entail, chalking out an endless succession of heirs. Latterly, indeed, the system has been so far modified by the interference of the legislature, that money is allowed to be be raised on the security of entailed estates for the effecting of necessary improvements, and certain provisions may made for widows and younger children. In consequence of these modifications, and of the abolition of the practice of letting entailed lands by fine, the practice is by no means so injurious as has been supposed, and as it has been frequently represented. Still, however, there can be no doubt of its extreme inexpediency in a public point of view; though, owing to the number of third parties interested in the succession to entailed estates, the question as to the abolition of entails is one of the greatest difficulty.

In England, on the other hand, it seems as if the legislature had hit the happy medium between giving too much and too little power to those who have accumulated property over its disposal by will. An English gentleman may entail an estate on such heirs as are in existence when the deed is executed, or till the first unborn heir be 21 years of age; but here the destination stops, and the heir in possession has then the absolute disposal of the property. This gives to every one that degree of power over his property which is required to inspire him with the desire of accumulating a fortune; at the same time that it takes from him the power of legislating for future ages, or of creating rules to be obeyed in all time to come.

French Law of Succession.—We have already seen that it has been the practice in most countries, as society advanced, to relax the restraints imposed in early and less enlightened ages on the bequeathing of property by will. But the modern legislators of France have followed a different course, and have confined the power of testators within the narrowest limits. They have, in fact, gone far to make that rule of the Roman law, as to equal partition among all the children, that obtained in cases of intestacy, the imperative rule of succession to all property, whether landed or moveable.

According to the new French law, a person with one child may dispose at pleasure of a moiety of his property, the child inheriting the other moiety as matter of right; a person having two children is only allowed the absolute disposal of a third part of his property; and those having more than two must divide three fourths of their property equally amongst them, one fourth part only being left at their own disposal. The property of those dying intestate is equally divided amongst their descendants, without respect of sex or seniority.

This law was intended to subvert the foundations of that feudal aristocracy whose ascendency had been very prejudicial to France; and as the influence of an aristocracy must always be mainly dependent on the magnitude of their property, it was certainly well fitted to accomplish its object. It is seldom, however, that a law adapted to a particular emergency may be maintained with advantage as a general rule of national policy; and it would be singular were a device originally fallen upon for the express purpose of splitting estates found beneficial for regulating the succession to property in a great kingdom. Considered in a general point of view, this law seems infinitely more objectionable than a system of perpetual entail. By interfering to so extreme an extent in the disposal of a man's property, it must plainly lessen the motives to accumulation; while, by rendering all the children in a great measure independent, it weakens the parental authority, and has the same injurious operation in reference to an entire family that the law of entail has in reference to a single child. When the property of the father must be divided, all his descendants are aware, from their earliest infancy, that they are, without any peculiar merit or exertion on their part, to obtain a certain provision; and can any one doubt that this sort of certainty must tend to paralyse their efforts, and to render the younger children at least less enterprising than they would be, did they know that their condition in society was to depend principally on themselves, and that they had no security, other than their own deserts, for obtaining any thing from their parents? But even these do not seem to be its worst effects. The inevitable tendency of this, and of every similar system, is to occasion too great an increase of agricultural population; at the same time that it operates to reduce landed property into such minute portions as neither to afford sufficient employment to the families occupying them, nor to allow of their being cultivated and improved in the best and most efficient manner. The strong predilection entertained by the great bulk of the children of persons engaged in the business of agriculture for the pursuits of their fathers has been remarked by every

one in any degree familiar with rural affairs; and it is obvious that the existence of a law making the division of estates compulsory affords the greatest facilities for gratifying this inclination. It will give to many, who might otherwise have been obliged to emigrate, or to resort to some other employment, the power of continuing in that line of life in which they have been educated, and which is endeared to them by those early associations that exert so strong an influence over future conduct. Should a family be unusually large, or should the share of the paternal property falling to each of the children be insufficient to enable them to maintain themselves in nearly the same class as their father, some of the more adventurous spirits will probably be disposed to sell their portion, and to engage in other pursuits. But experience shows that, in the great majority of cases, they continue to reside on the little properties obtained from their ancestors; and the fair presumption seems to be, that the process of division and subdivision will continue, until the whole land has been parcelled out into patches, and filled with an agricultural population, destitute alike of the means and the desire of rising in the world.

It is no doubt true that the condition of the agriculturists of France, at this moment, is decidedly superior to what it was previously to the Revolution. But it cannot be truly affirmed that this improvement has been in any respect owing to the law of equal inheritance. It has taken place, not in consequence of that law, but in despite of it. The abolition of the feudal privileges of the nobility and clergy, and of the gabelle, corvées, and other oppressive and partial burdens and imposts, was of the greatest service to proprietors and farmers; and, in addition to these advantages, a great part of the property of the church and of the emigrants came into their hands at very low prices; so that small properties were augmented, and fresh energy given to agricultural pursuits. Still, however, it is certain that the rapid subdivision of landed property, and the continually increasing excess of the agricultural population, caused by the law of compulsory succession, have gone far to neutralize the effects of these advantageous circumstances, and form at this moment one of the most deeply-seated evils in the social condition of the people of France.

In every respect, therefore, this law would seem to be most inexpedient; and certainly the experience of France does not tend in any respect to shake our belief in the wisdom of those who contend that the interference of the legislature in respect to wills should, in all ordinary cases, be confined within the narrowest limits; and that in this, as in most other things, their object should rather be to prevent abuses, than to enact rules for the guidance of individuals in the distribution of their property under ordinary circumstances.

Bequeathing of Property for Charitable Purposes. — In the article FOUNDATIONS in this work, we have briefly glanced at some of the more prominent considerations that should be attended to in the endowment of hospitals, and in the appropriation of property for purposes of public utility. No doubt it is of the greatest importance, in a national point of view, that property should be bequeathed for such objects; and it would be easy to show that England has derived, and is deriving, the greatest advantage from the bequests of private individuals for the promotion of education, the support of the poor, and other charitable purposes. Still, however, it seems abundantly obvious that such bequests should in all cases be subject to the control of the state. It is difficult indeed, or rather impossible perhaps, to define, *à priori*, how far interference should be carried in such cases; but that, speaking generally, it is indispensable even to the proper carrying out of the views of the testators, is abundantly obvious.

To regard the instructions in the wills of those who have established foundations as immutable laws, which are in no case to be altered, is, in truth, to permit the ignorance, folly, or presumption of an individual to become a standard for all future ages, and to regulate the studies and the institutions of a more advanced and enlightened period by his crude conceptions and views. Surely, however, it is needless to say, that no select number of men, and still less individuals, should be allowed to erect themselves into infallible legislators for every succeeding generation. The regulations of the great Alfred and the other benevolent individuals who founded the Universities of Oxford and Cambridge may have been excellent at the time when they were framed; but had they been strictly adhered to, their chairs must now have been filled with Aristotelian doctors, and lecturers on the Ptolemaic system of the world and the infallibility of the Pope!

It is impossible to doubt the pious and benevolent views of many of those who, in the middle ages, left their property to monastic institutions; but still less is it possible to hesitate applauding the conduct of the reformers, who diverted this property to other purposes, and who justly considered that the terms of a will dictated in a comparatively barbarous period should not be permitted to consecrate and hallow a system which had been discovered to be most inimical to the interests of true religion, and productive only of injurious consequences.

The establishment of foundling hospitals is another instance of the same kind. They were projected, and have been kept up, with the best intentions; but it admits of demonstration, and is now, indeed, generally admitted, that they have been productive of an incomparably greater amount of crime and of mortality than they have obviated.

Even as respects the educational foundations established in many parts of England, no one can doubt that their utility is in very many instances greatly narrowed, and in not a few wholly nullified, by the injudicious rules laid down for their government; and, in fact, there is nothing that stands in greater need of revision and amendment than the constitution and administration of foundations.

SUCCE'SSION. In Civil Law. In that jurisprudence, and those modern systems which are derived from it, there is no distinction between moveable and immoveable property, considered as a subject of succession. Succession, whether of real or personal property, is either *ab intestato*, or by testament. The order of succession ab intestato, according to the civil law (*see* DESCENT), is to be found in the laws of Justinian (*Novell*, 118. 127, &c.). It admits three classes of successors, — descendants, ascendants, and collaterals, who are preferred in that order in the succession; so that if a man leave any descendants, all ascendants and collaterals are excluded; and ascendants exclude collaterals, except brothers of the whole blood and their children. The children of the deceased partake equally. Stepchildren are strangers to the succession of their step-parents. Children, the issue of several marriages, succeed equally to the property of their father; but severally to the property of their respective mothers. Grandchildren take *per stirpes*, or by right of representation; *i. e.* if a child die in the parent's lifetime, his children divide his share equally. Among descendants, he or she of the nearest degree is preferred, and there is no right of representation. Brothers and brothers' children per stirpes divide with parents; but it is doubtful whether or no more distant ascendants divide with them. Succession among collaterals is said not to extend beyond the 10th degree. The wife (by *Novell*, 53. c. 6.) succeeds, under certain circumstances, to a fourth.

SUCCI'NEA. (Lat. succinum, *amber.*) A genus of freshwater Gastropods, so called from the transparent texture and amber colour of the shell. Of this genus two species (*Succinea amphibia*, Drass., and *Suc. oblonga*) are British, and to be found occasionally in the river Wandle, and in Greenwich marshes.

SU'CCINIC ACID. (Lat. succinum.) An acid obtained among the products of the destructive distillation of amber; when pure it is a white crystalline substance. Its salts are termed *succinates;* of these the *succinate of ammonia* is occasionally used as a test for iron. It precipitates the peroxide of that metal in the form of a brown insoluble succinate.

SU'CCINITE. (Lat. succinum.) An amber-coloured garnet.

SUCKING PUMP, or SUCTION PUMP. The common construction of the pump, in which the two valves open upwards. *See* PUMP.

SUCTO'RIANS, *Suctorii.* (Lat. sugo, *I suck.*) The name of a tribe of Cartilaginous fishes, comprehending those which, like the lamprey, have a circular mouth adapted for suction.

SU'ET. The fat situated about the loins and kidneys, which is harder and less fusible than that from other parts of the same animal. That of the ox and sheep is chiefly used; and when melted out of its containing membranes it forms tallow, and is largely used in the manufacture of candles and the ordinary soaps. Beef and mutton suet, when fused, concrete at a temperature of about 100. Like other kinds of fat, it is a compound of carbon, oxygen, and hydrogen.

SUFFE'TES. (Said to be from the Phœnic. schopetim.) Certain Carthaginian magistrates, whose office bore considerable analogy to that of the Spartan kings and Roman consuls. Their number was two, and they were elected annually from the noblest families of the state. The functions of the suffetes seem principally to have been confined to the management of civil affairs. Thus it was their province to assemble the senate and preside in it, and also to propose the subjects of debate, and collect the votes; but there are instances recorded of suffetes leading the armies of their country. All the cities of note in the Carthaginian dominions had likewise their suffetes; but these, of course, were invested merely with municipal authority. (See *Mém. de l'Ac. des Inscr.* vols. xxxiv. xxxviii.)

SU'FFRAGAN. In Ecclesiastical Usage, every bishop is said to be suffragan, relatively to the archbishop of his province; thus the bishop of Carlisle is suffragan to the

archbishop of York, &c., either on account of the suffrages given by them in the provincial synods, or because they cannot be consecrated without the *suffrage* or consent of the archbishop. Titular bishops, ordained to assist a bishop in his spiritual functions, are also commonly, but rather improperly, styled suffragans; a title adopted by the stat. 26 H. 8. c. 14.

SU'FFRAGE. *See* PARLIAMENT.

SUFFRAGO. (Lat. suffrago, *the pastern.*) In Mammalogy and Ornithology, the joint of the tibia with the tarsus.

SUFFRU'TICOSE. (Lat. suffrutex, *an undershrub.*) Any plant which is not exactly either a shrub or an herbaceous plant; that is, which has not hard woody twigs and complete buds like the one, nor perishable succulent twigs like the other. Lavender is an instance of a suffruticose plant.

SU'GAR. (Fr. sucre, Germ. zucker.) The great commercial demand for sugar is almost exclusively supplied from the sugar cane (*Arundo saccharifera*), which contains it in greater quantity and purity than any other plant, and consequently affords the greatest facilities for its extraction. A large quantity of sugar is contained in the sap of the American maple (*Acer saccharinum*), and in the juice of the beet-root (*Beta vulgaris*), from both of which it may be economically obtained; it has also been extracted from grapes or raisins, and, as is well known, is contained abundantly in many ripe fruits and esculent vegetables. It is, however, in these, seldom so pure or in such quantity as to admit of ready separation.

The process, as carried on in our West India islands, consists in pressing out the juice by rolling mills, and carefully evaporating it till it has acquired the proper consistency for crystallizing; lime water is added during this operation, to neutralize any free acid, and to facilitate the separation of certain vegetable matters, which, in consequence of the action of the lime, rise more readily to the surface, and admit of being skimmed off. When duly concentrated, the syrup is run off into shallow wooden coolers, where it concretes; it is then put into barrels with holes in the bottom, through which a quantity of treacle or molasses gradually drips, and the remaining sugar acquires the granular crystalline state; it is packed into hogsheads, and comes to us under the name of *raw* or muscovado sugar. The following is a sketch of the process by which raw sugar is purified in this country. Raw sugar is chosen by the refiner by the sharpness and brightness of its grain; it is put into a copper pan or boiler, previously charged with a certain quantity of lime water, with which a portion of bullocks' blood has been well mixed by agitation, and is suffered to stand a night to dissolve. Early in the morning fires are lighted under the pans, and when the liquid boils the coagulated albumen of the blood rises to the surface and carries the impurities of the sugar with it. The liquid is kept gently simmering, and continually skimmed, till a small quantity, taken out in a metal spoon, appears perfectly transparent: this generally takes from four to five hours. The clear syrup is then run off into a cistern; the pans are reduced to half their former size, by taking off a moveable front, and a smaller portion of the purified syrup returned into each; the fires are now increased, and the sugar made to boil as rapidly as possible, till a small quantity taken on the thumb is capable of being drawn into threads by the fore-finger; the fire is then damped, and the boiling syrup carried off in basins to the *coolers;* a fresh quantity is then pumped into the pans and evaporated as before. In the coolers the sugar is violently agitated with wooden oars till it appears granulated. It is upon this agitation that the whiteness and fineness of grain in the refined sugar principally depend; the crystals are thus broken down whilst forming, and the whole converted into a granular mass, which permits the coloured liquid saccharine matter to run off, and which would be combined with the solid if it were suffered to form into larger crystals. This granular texture likewise facilitates the percolation of water through the loaves in the after process, which washes the minutely divided crystals from all remaining tinge of molasses. That this is the real theory of the whitening of sugar by the process of refining appears from a comparison with the process for making *sugar candy.* In this the raw material is cleared and boiled as above; but instead of being put into coolers and agitated, it is poured into pans, across which threads are strung, to which the crystals attach themselves; these are set in a stove, and great care is taken not to disturb the liquid, as upon this depends the largeness and beauty of the candy. In this state it is left for five or six days exposed to a heat of about 95°; when it is taken out and washed with lime water. This takes off the molasses from the outside; but a great quantity is combined in the crystal, and the consequence is that candy is never whiter than the sugar it is made from. When the sugar has attained the granular state in the coolers, as above described, it is poured into conical earthen moulds, which have been previously soaked a night in water; in these it is again stirred, for the purpose of extricating the air-bubbles, which would otherwise adhere to the surface and render it rough; when sufficiently cold, the loaves are carried to some of the upper floors of the manufactory, and the paper covers being removed from their points, they are set with their broad ends upward upon earthen pots. The first portions of the liquid molasses soon run down, and leave the sugar much whitened by the separation; afterwards, pipe-clay mixed with water to the consistence of cream is put upon the base of the loaves to the thickness of about an inch; the water from this clay gradually filters through the loaf, and carrying with it all remaining tinge of molasses, runs into the pot, the clay being of no other use than to retain the water and prevent its too rapid percolation, by which too much of the solid sugar would be dissolved. This process, called *claying*, is repeated four or five times, according to the nature of the sugar and the degree to which it has been boiled. When the loaves are thus cleansed from all relics of colour they are suffered to remain some time for the water to drain off; when this is completed, they are set with their points upwards, when all remains of it are equally diffused throughout; they are then *stove-dried* at a temperature between 95 and 100. The syrup, or drainings collected in the pots, is mixed with the raw sugar in the next boilings: it is divided according to its fineness; the first runnings, which are the foulest, being reserved for the coarsest loaves; while the last, being little else than clear syrup, is boiled into loaves of the same fineness as those from which it ran. The lowest syrups are boiled into what is called *bastard sugar*, from which the molasses runs with very little mixture of solid sugar: this it is which is sold under the name of *treacle*, being quite incapable of further crystallization. The average produce of 100 cwt. of raw sugar treated as above is 63 lbs. of refined, 18 of bastard, 27 of molasses, 4 loss in dirt, &c.

Mr. Howard, in his patent process for the refining of sugar, introduced a variety of modifications and improvements, the principal of which depended upon boiling under diminished atmospheric pressure, so that no part of the syrup was liable to be burned or otherwise injured by heat; he also employed recently precipitated aluminous earth to abstract part of the colouring matter; well-burned charcoal, especially animal charcoal, has been found very serviceable for the latter purpose, and a number of other improvements in and modifications of the process of refining have more lately been adopted.

The chemical characters of sugar are well defined, especially those of the crystallizable or cane sugar. Its specific gravity is about 1·6. It dissolves in all proportions in water, is less soluble in alcohol, and is recognized by its purely sweet taste. It is blackened by sulphuric acid; and when about one part of this acid is added to two of thick syrup, the mixture presently boils up into a black frothy mass, which is little else than carbon, acid, and water. In respect to ultimate composition, sugar belongs to that important class of proximate vegetable principles which are theoretically regarded as compounds of carbon and water; that is, of carbon and of oxygen and hydrogen, in the same relative proportions as they exist in water. The following shows the results of Dr. Prout's analysis of the finest loaf sugar in a dry and pure state, with its probable atomic constitution:—

	Atoms.	Equiv.	Theory.	Expt.
Carbon -	- 9	54	42·86	42·85
Hydrogen -	- 8	8	6·35	6·35
Oxygen -	- 8	64	50·79	50·80
	1	126	100·00	100·00

Several other varieties of sugar have been chemically examined; such as grape sugar, honey sugar, mushroom sugar, manna liquorice sugar, &c.

Consumption and Supply. — Sugar is to be ranked rather as a necessary than as the most desirable of luxuries; and a larger sum is, we believe, expended on sugar in this country than on anything else, excepting corn and butcher's meat. The sugar consumed in England is all derived from the *Arundo saccharifera*, or sugar cane, and was, for a lengthened period, almost wholly supplied by our colonies in the West Indies; but latterly we have derived very extensive supplies from the Mauritius and India. Foreign sugar is virtually excluded from our markets by the prohibitory duty with which it is loaded.

Besides the West Indies, South America, especially Brazil, the East Indies, the Mauritius, Java, Siam, the Philippine Islands, &c. are the countries which export by far the largest supplies of cane sugar, though it either is or may be produced in most tropical countries, and it is also cultivated to some extent in some countries within the temperate zone. During the last war, when the nations of the Continent experienced very great difficulty in getting supplies of sugar from tropical countries, attempts were made to raise it at home from beet-root; and this sugar being exempted from the heavy duty laid on colonial sugar, its culture has latterly

been very greatly extended, especially in France. But the general opinion seems to be, that were beet-root sugar subjected to the same duty as colonial sugar, its culture would have to be abandoned. We subjoin

An ACCOUNT of the Quantities of the different Descriptions of Sugar entered for Consumption in the United Kingdom during each of the Eleven Years ending with 1840; with an Account of the Amount of Duty received on the same, the average Price of Muscovado Sugar in Bond, &c.

Duty on East Indian sugar from 1830 to 13th of August, 1835	1	12	0	—
Duty on ditto of any British possession within the limits of the East India Company's charter into which the importation of foreign sugar is prohibited, and imported from thence from 13th of August, 1835, to 1840	1	4	0	—
Duty on ditto of any other British possession within those limits, and imported from thence from 13th of August, 1835, to 1840	1	12	0	—
Duty on foreign sugar from 1830 to 1840	3	3	0	—

Additional 5 per cent. on the above rates from 16th of May, 1840.

SU'ICIDE, or SELF-MURDER. (Lat. suicidium.) Few chapters in the history of the human mind are more singular than that of suicide, as showing the kind of honour and estimation which a practice so unnatural has attained in the feelings of many nations. The rank which religious suicide has held from immemorial antiquity, and still holds, in the opinion of the Hindoos, has been too often described, and is too familiar in its most notorious and painful instances, to need more than adverting to on the present occasion. It is said that the practice is condemned by their older books; if so, the traditionary sentiments of the people have been formed on some different model. The suicides of the Hindoos have proceeded partly from fanaticism, partly from an apathetic philosophy; those of the ancient Scandinavians, esteemed equally honourable, from the overflow of courage in warriors, who could endure any evil except the approach of helpless and unwarlike old age.

Among the Greeks, the first inquirers who reasoned out the principles of human life and action by a train of philosophical investigation, singularly vague and discrepant opinions on this subject seem to have prevailed; as might have been expected from a people to whom religion furnished so very few fixed data of reasoning, and by whom abstract truth was pursued with such unequalled ingenuity and earnestness. Socrates, the great master of ethics, was emphatic in his condemnation of suicide. Plato speaks in a more dubious strain: writing as a lawgiver, he reprobates it; and in his arguments on the subject is to be found the well-known illustration which has figured ever since in all such discussions, in which he compares it to the desertion by a soldier of his post; yet he expressly excepts from his censure those cases in which it is committed under the pressure of immitigable calamity. Pythagoras, at an earlier period, denied its lawfulness. (See *Athenæus*, l. iv.) In the later days of Greek philosophy, both Stoics and Epicureans found arguments for its defence in their respective principles. The former sect was most notorious for its tenets on this subject; Zeno and Cleanthes, its great masters, having both put an end to their own lives, as Democritus had done before them, from the mere tedium of old age.

Cum jam matura vetustas
Admonuit memorem motus languescere mentis,
Sponte suâ letho caput obvius obtulit ipse.

The argument of an Epicurean philosopher on the topic may be collected from *Cic. Tusc. Disp.* v. 41.; and, indeed, may be compressed in the pithy Greek motto for a drinking party, 'Η πῖθι, ἢ ἄπιθι — *drink, or begone.* "Stoical academics" (says Dr. Moore in his *Essay on Suicide*, i. 233.), "if such an expression be warrantable, would plead a dismission whenever their diginity was affronted or their glory diminished; whilst Epicurean academics would care nothing about such matters, as long as their personal indolence and tranquillity were not superseded." The influence of Greek philosophy had, as is well known, a great share in producing that tendency to suicide which distinguished the higher society of Rome in the later days of the commonwealth. The "Roman death," as it is emphatically called, was not really a national habit; the older manners of the commonwealth repudiated it; its prevalence was owing to foreign doctrines, acting on minds affected by the violent passions, engrossing luxuries, and rapid vicissitudes of fortune which distinguished that momentous era. Virgil returns to the Pythagorean view; and, without inveighing against suicide, represents it as a sad and mournful death, the perpetrators of which are doomed to a long and shadowy existence, — without torment, but without enjoyment; one which they would willingly exchange for the bitterest poverty and labour in the cheerful light of day. Perhaps the courtier-poet was a little affected by the feelings of those in power, who loved to have contented, orderly, and not too irritable subjects, and disliked the fashion among the noble Romans of escaping in this manner from tyranny and persecution. At a later period suicide committed by criminals under accusation was made criminal by the Roman law. This was with a view to preserve the forfeiture of the criminal's property to the government. Suicide, as such, does not seem to have been the subject of legislation.

Although Christianity was not slow in effecting a reform in the feelings of mankind on this important subject, yet some relics of the ancient sentiments lingered awhile, even in the minds of enlightened believers. The fanatical Donatists were greatly addicted to suicide, and are justly condemned on this account among others by the early writers of the church. Nor did these latter ever esteem suicide lawful, even under the severe persecutions to which the church was subjected, except perhaps in one case — when committed by virgins to preserve their chastity. The cherished sentiments of the fathers of the church on this subject rendered them not only lenient to such victims of honour, but some of them have even gone so far as to commend them. Augustine, with his usual strong sense of moral right, only pities them; and expressly classes all suicide as homicide. (*De Civ. Dei*, l. i. c. 19.) There was, at an early period, no commemoration for the souls of suicides in the early church. And the council of Bracara, A. D. 563, refused them Christian burial; a measure which has been pretty generally adopted throughout Christendom.

There have been a few paradoxical writers who have contended in favour of the lawfulness of suicide, arguing on Christian premises. In *Hume's Essay on Suicide* this ground is taken, with the author's usual adroitness in pointing out supposed deficiencies in the scheme of Revelation. A more remarkable instance is Dr. Donne's "*βιαθανατος*; or, a declaration of that paradox or thesis, that self-homicide is not so naturally sin that it may never be otherwise." It is remarkable, however, less from the force of the argumentation, than the circumstance that a man of a religious, though eccentric turn of mind, should have defended such positions. Some of his arguments, those derived from the silence of Scripture on the specific subject, have been commonly repeated: others seem very puerile. Those who wish it will find them seriously refuted, at much length, by the painstaking Dr. Moore, in his *Essay on Suicide*, already quoted, from which we have taken most of this historical sketch. To say the truth, his refutation is in some instances as weak as any part of Donne's paradox.

Among the writings of another class of thinkers, the reasonings *pro* and *con* urged by Rousseau in the *Nouvelle Heloise* are well known. Though there is little convincing in the logic of the antagonist of suicide, yet the side he takes is made to appear the generous and noble one; and in this case, as in several others, Rousseau must be owned to have done service to the cause of morality, considering the incredible influence which he exercised on the fervid heads and hearts of his time. It is remarkable that Lord Edward, in the work above

alluded to, is made to admit one exception in favour of suicide, in the case of acute and irremediable pain. Madame de Staël, in her *Essay on the Influence of the Passions*, advanced a sort of defence of suicide; in her later work (*Reflexions sur le Suicide*, published in 1810) she has enforced the more customary doctrine with much eloquence and feeling. We are not acquainted with the work of the Swedish professor Robeck in defence of suicide (who killed himself after writing it), except through the mention made of it by Dr. Moore and Madame de Staël.

In discussions on the subject of proneness to suicide in particular classes or nations, it is impossible to disconnect it from that of insanity; because the miserable delusions of that disease constantly impel their victim to its commission. In societies, therefore, where insanity is most common, the number of suicides will be greatest. It does not follow that the number of suicides committed by persons not insane will also be greatest in such societies; that is, when we disregard the refinements of those who profess to consider suicide itself as a proof of greater or less derangement of the mental functions. What we mean by the suicide of a sane person is, the suicide of one of whose insanity there is no evidence except such as may be considered to arise from the act itself. Considered in this light, the tendency to deliberate suicide has been almost epidemic in many communities. Nor does it arise from similar causes, or in similar states of society. Among the old Scandinavians, as at this day with some tribes of savages, it was the offspring of the intolerance of fierce dispositions of the helplessness of age and disease. It prevails, too, sometimes in effeminate communities, where there is little zest or excitement in life, with mean habits, little self-respect, and much apathy: thus it is extremely common in China, even, it is said, among the lower classes, notwithstanding the proclamations, full of ethical saws, which the magistrates issue against its commission. Among people of minds thus disposed, the act is generally deliberate, and unconnected with insanity; so, again, where it results from a cold temperament, and a sarcastic and contemptuous view of life, which was the notion formerly entertained by foreigners of the English mania for suicide; a notion which probably had not much foundation in truth at any time. Sixty years ago, Mercier (*Tableau de Paris*, vol. iv.) thought it prevailed less in England than France. At present, in communities civilized on the European model, it would probably be found that the number of suicides was pretty nearly in proportion to that of insane persons, and that the same causes which produce mental disturbance lead likewise to self-murder. Perhaps the principal predisposing influences, as they affect society in the mass, may be reduced to four: — the spirit of mercantile speculation, leading to sudden and overpowering vicissitude of prosperity and want; mental excitement, produced chiefly by misdirected education, literature, and philosophy; absence of self-restraint, especially on religious principles; and intemperance in spirituous liquors. Either of these causes alone may be sufficient: for example, in various parts of northern Germany, and in Geneva, where there is little of commercial movement, and where the body of the people are orderly and well-conducted, suicide is nevertheless extremely common among the educated classes, and may be referred almost wholly to mental excitement. But where they all combine, the effect is fearful; as may be witnessed in the great cities of France and the United States. On the other hand, suicide is rare in nations where fatalism prevails, as among the Turks and Spaniards; in nations in which a love of order is joined with an unrefined mental organization and great love of physical enjoyment, such as the south Germans, and to a certain extent the Italians. The following table exhibits some of the results given by M. Quetelet, from researches extending over a number of years, from 1820 downwards; but we give them, premising our doubt as to the possibility of obtaining accurate returns in many countries.

Number of Suicides annually, compared with the Population.

Russia	1 in 49,182
Austria	— 20,900
France	— 18,000
Pennsylvania	— 15,875
Prussia	— 14,404
New York (State)	— 7,797
City of London	— 5,000
City of Berlin	— 2,941
City of Geneva	— 2,941
City of Paris	— 2,400

With regard to classes, the number of suicides is probably distributed in a pretty equally diminishing proportion from the highest to the lowest: with the exception, however, of crowned heads; for it has been observed that no sovereign, at least in modern times, was ever known to commit self-murder. There is a remarkable paper in the first volume of the *Journal of the London Statistical Society*, showing its prevalence among the military in this city. The suicides in the Dragoon Guards and Dragoons are said to amount to one twentieth of all the deaths; while among the members of the Equitable (to make the comparison with a body of grown-up persons) they are only 1 in 110.

With respect to the causes of suicide, some curious results have been obtained by statisticians; but, in giving them, we must profess our doubts concerning the value of such statements, from the very vague data on which they must necessarily be founded. It appears from a classification of 134 suicides committed in ten years at Geneva (by M. Prevost, in the 15th vol. of the *Annales de Hygiène*), that the following causes produced them: —

Disease	34
Mental alienation	24
Pecuniary misfortunes	19
Domestic "chagrins"	15
Melancholy, cause unknown	13
Misconduct, drunkenness	10
Fear of punishment, remorse	6
"Chagrins" of love	6
Gambling and lotteries	4
Mysticism	2

Comparing these with other accounts, it would seem that love produces at Paris $\frac{1}{26}$ of the suicides committed, at Geneva $\frac{1}{22}$, at Petersburg $\frac{1}{5}$, if Mr. Schön is to be believed; a singular contrast to the commonly supposed effects of climate. Domestic griefs at Paris (from 1794 to 1823), $\frac{1}{9}$; at Geneva the same. Misconduct at Paris $\frac{1}{23}$, at Geneva $\frac{1}{13}$, at Petersburg $\frac{1}{4}$. Gambling at Paris $\frac{1}{43}$, at Geneva $\frac{1}{14}$. Some of these results, in Paris and Geneva, are certainly remarkable for their correspondence. (See an Essay of M. Brouc, in the 16th vol. of the *Annales de Hygiène*, already cited. The reader may consult also M. de Villeneuve Bargemont, *Econ. Politique Chrétienne.*)

The following statement is extracted from the official tables of revenue, trade, and population for 1839: —

Number of suicides in England and Wales during the year ended 30th of June, 1839...Males, 751; Females, 307.

The Ages of 1044 Suicides.

Between the ages of 10 and 15	8
— 15 — 20	73
— 20 — 30	151
— 30 — 40	172
— 40 — 50	217
— 50 — 60	221
— 60 — 70	141
— 70 — 80	54
— 80 — 90	14
— 90	2

From this it appears that the greatest number of suicides (relatively to the numbers living) are between the ages of fifty and sixty (which appears from M. Prevost's calculation to be also the case at Geneva); the tendency to suicide regularly increasing up to the latter age. Between seventy and eighty the number is still very considerable.

The Season of the Year.	Males.	Females.
January, February, March	163	66
April, May, June	210	94
July, August, September	214	73
October, November, December	164	74
	751	308

Thus the proportion of male to female suicides is $2\frac{1}{4}$ to 1; at Geneva exactly the same (95 to 38). The subject must not be dismissed without noticing the great increase of suicide which most observers represent to have taken place in the last twenty years, especially in the large towns of northern Europe. But there must be a certain degree of doubt how much of the apparent increase is owing to more accurate observations.

Suicide is ranked by the English law as a peculiar species of felony; and, like other felonies, cannot be committed by persons under the age of discretion, or insane. From very ancient times (see *Bracton*) the law imposed the forfeiture of personal property as a consequence of it; and a felo de se (as a wilful suicide is termed) forfeits all chattels, real and personal. But the offence was never attended with corruption of blood, or the forfeiture of lands of inheritance; so that the will of a felo de se stands good as to realty. In order to vest these chattels in the crown, the fact of self-murder must be proved by an inquisition, which the coroner is the proper officer to hold. In addition, the law formerly required that a self-murderer should be buried in a highway, with a stake driven through his body. Now, by 4 G. 4. c. 52. his remains are to be privately buried at night in the churchyard. But the canon law (confirmed by the rubric in the Common Prayer Book) forbids the performance of Christian rites over them.

SUIT. In Law, the same as *action;* which see.

SULCATE. (Lat. sulcus, *a furrow.*) In Zoology, when a surface is deeply impressed with longitudinal parallel lines.

SU'LPHATES. Salts containing sulphuric acid; green vitriol is a *sulphate* of the protoxide of iron. Glauber's salt is a *sulphate* of soda.

SU'LPHITES. Salts of the sulphurous acid.

SU'LPHOCYA'NIC ACID. This acid was discovered in 1808, by Mr. Porrett, who ascertained it to be a compound of sulphur, carbon, hydrogen, and nitrogen; he called it *sulphuretted chyazic acid*, the term chyazic being composed of the initials of carbon, hydrogen, and azote. It is best formed by distilling a strong solution of sulphocyanuret of potassium with phosphoric acid, when sulphocyanic, or more properly *hydro-sulphocyanic*, passes over into the recipient, and phosphate of potassa remains in the retort. So obtained, it is a liquid of a slight pink hue, and smells somewhat like vinegar. The strongest solution has a specific gravity of 1·022; boils at 217°, and crystallizes at 55° in six-sided prisms. It gives a very characteristic deep red solution with persalts of iron; with a salt of copper it gives a white precipitate. It is composed of

	Atoms.	Equiv.
Sulphur - - -	2	32
Cyanogen - - -	1	26
Hydrogen - - - -	1	1
	1	59

Sulphocyanuret of potassium is obtained by mixing equal weights of powdered sulphur and ferrocyanate of potassa, and keeping them in fusion for half an hour in a flask; when cold, reduce the mass to powder, and digest it in water; filter the solution, and add a sufficiency of liquid potassa to throw down the iron.

SU'LPHONAPHTHA'LIC ACID. A compound of sulphuric acid and naphthaline, discovered by Mr. Faraday. (*Phil. Trans.* 1826.)

SU'LPHOSINA'PISIN. (Lat. sulphur, and sinape, *mustard.*) A crystallizable substance obtained from mustard seed; it appears to contain sulphur, carbon, hydrogen, and nitrogen.

SULPHOVI'NIC ACID, *Œnothionic Acid.* An acid formed by the action of sulphuric acid upon alcohol. From Mr. Hennel's experiments (*Phil. Trans.* 1826 and 1828) it appears to be a compound of

	Atoms.	Equiv.
Sulphuric acid - - - -	2	80
Quadri-hydrocarbon - - -	1	28
	1	108

SU'LPHUR, *Brimstone.* A yellow brittle mineral product, found in various parts of the world; but apparently most abundant in volcanic regions. Europe is chiefly supplied with it from the south of Italy and from Sicily. It most commonly occurs massive; but it is sometimes met with crystallized in the form of an oblique rhombic octoedron. Fine specimens of this description are seen in our mineral cabinets, and bear a high price. A considerable quantity of sulphur is also obtained from some of its metallic combinations, such as the sulphurets of copper and of iron. These ores are heated, or roasted, as it is termed, in furnaces so constructed that the sulphur vapour may be condensed, and from time to time collected; this, when purified by fusion, is cast into moulds, and forms common or *roll brimstone.* Small quantities of sulphur also occur in several animal and vegetable products, and are frequently recognized by the odour of sulphuretted hydrogen which they evolve during putrefaction. Sulphur is a non-conductor of electricity, insipid, and inodorous, unless rubbed or heated, when it evolves a sulphurous smell. Its specific gravity is 1·99. It melts at about 216°; and when heated to about 250° it becomes a limpid, amber-coloured liquid; if the heat be raised to about 450°, it again becomes viscid and deeper coloured; at 480° up to its boiling point it acquires rather more fluidity; at about 600° it rises rapidly in vapour, and in close vessels condenses in the form of a fine yellow powder, composed of crystalline grains: in this state it is called *flowers of sulphur.* The earthy and metallic impurities which, with a portion of sulphur, remain in the subliming vessel, were formerly called *sulphur vivum.* When sulphur in its viscid state of fusion is poured into water it becomes a ductile mass, which slowly hardens, and which is often used for taking impressions of seals and medals. When sulphur is in the form of vapour it is of a dense orange colour; its specific gravity in that state is about 6·6, and 100 cubic inches of it should therefore weigh about 206 grains.

There is another form of sulphur which is sometimes called *milk of sulphur* (lac sulphuris), and which is a *hydrate of sulphur;* it is obtained by precipitating sulphur by muriatic acid from certain of its alkaline solutions. When sulphur which has been melted is suffered to cool slowly, its interior often exhibits prismatic crystals, and very beautiful specimens of this artificial crystallization of sulphur may be obtained by melting a few pounds of it in a crucible or ladle, and when partially cooled piercing the outer crust and inverting the vessel, so that the interior liquid part may run out; on breaking the mass when cold, the cavity will be found lined with prismatic crystals.

The results of the combustion of sulphur, its equivalent number (16), and several other details respecting its combinations and uses, are given under the heads of SULPHURETTED HYDROGEN, and of SULPHURIC and SULPHUROUS ACIDS.

Sulphur is insoluble in water; it dissolves in boiling oil of turpentine, and is deposited often in crystals as the solution cools. It is also soluble in alcohol, if both substances be brought together in the state of vapour. It combines also with chlorine, bromine, and iodine. Its native combinations with the metals form some of the most important ores. It is from the sulphurets of lead and of copper that the commercial demands for these valuable metals are almost exclusively supplied.

Sulphur is of great importance in the arts. It is used extensively in the manufacture of gunpowder, and in the formation of sulphuric acid, or oil of vitriol. It is also used in medicine, and for other purposes of the arts. The entries for home consumption in 1838 and 1839 amounted, at an average, to 695,056 cwt. a year. The duty on refined or roll brimstone varies from 6*s.* to 9*s.* 9*d.* a cwt., whereas on rough it is only 6*d.*; so that the imports consist almost wholly of the latter. The largest portion by far of the imports come from Italy, or rather Sicily. The price of rough brimstone in bond in the London market usually varies from 6*l.* 10*s.* to 7*l.* 10*s.* a ton.

SU'LPHURETS. Compounds of sulphur with electropositive or inflammable bodies. The most common ores of copper and of lead are *sulphurets* of those metals.

SULPHURETTED HYDROGEN, *Hydro-sulphuric Acid.* A gaseous compound of 1 atom of sulphur = 16 + 1 atom of hydrogen = 1. The equivalent, therefore, of sulphuretted hydrogen is 17. This gas was first examined by Scheele in 1777. It may be obtained by acting upon sulphuret of antimony by muriatic acid, or upon protosulphuret of iron by diluted sulphuric acid, and is immediately recognized by its peculiar fetid odour, which is so diffusible that a single cubic inch of it escaping into the atmosphere of a large room is soon every where perceptible by its smell. It is very deleterious to respiration. 100 cubic inches weigh about 36 grains, its specific gravity compared with air being as 1180 to 1000, or, compared with hydrogen, as 17 to 1. It is liquefied by a pressure of 17 atmospheres at 50°. Water agitated with this gas takes up its own volume, and acquires a bitterish nauseous flavour, and the odour which characterizes Harrowgate and Aix-la-Chapelle waters, and which derive their chief peculiarities from the presence of this gas. Sulphuretted hydrogen extinguishes flame; but is itself inflammable in the contact of air, burning with a blue flame, and depositing during its slow combustion a portion of its sulphur. When mixed with excess of oxygen and inflamed, it explodes, and the mixture is converted into sulphurous acid and water. One volume of the gas requires one volume and a half of oxygen for its entire combustion, and the results are water, and 1 volume of gaseous sulphurous acid. This gas is immediately decomposed by chlorine and by iodine, which, if not added in excess, throw down its sulphur and combine with its hydrogen. It is unequivocally recognized by its peculiar odour, and by its blackening the salts of lead. Sulphuretted hydrogen, diluted with 20,000 measures of pure hydrogen, sensibly blackens a piece of paper which has been dipped into a solution of acetate of lead: white lead is also immediately discoloured by it; hence the mischief which it does to white paint, and to pictures. The aqueous solution of sulphuretted hydrogen reddens litmus; and inasmuch as it combines with certain bases, it is properly considered as a weak acid.

SULPHURIC ACID, *Oil of Vitriol.* This most important acid was discovered by Basil Valentine towards the end of the 15th century. It was formerly obtained by the distillation of green vitriol, and from its oily appearance it acquired the name, which it still bears, of *oil of vitriol.* In this country it is procured by burning a mixture of 7 or 8 parts of sulphur with 1 of nitrate of soda or of potash. The mixture is burned in a furnace so contrived that a current of air carries the products of the combustion into a large leaden chamber, the bottom of which is covered to the depth of a few inches with water. The principal products of the combustion of the above-mentioned mixture of nitre and sulphur are sulphurous and nitrous acids; and these, together with atmospheric air and aqueous vapour, form the contents of the chamber.

The sulphurous and nitrous acids, with a portion of water, combine to form a white crystalline substance, which, upon falling into the water of the chamber, is instantly decomposed. The nitrous acid imparts oxygen to the humid sulphurous acid, and so converts it into sulphuric

acid; whilst the nitrous acid, having lost oxygen, reverts to the state of *nitric oxide*, which is given out into the air of the chamber, from which it immediately again abstracts oxygen, and becoming nitrous acid, is again ready to acidify a new portion of sulphurous acid. The oxygen, therefore, is thus indirectly transferred to the sulphur, or to the sulphurous acid, from the atmosphere, through the medium of the attractive power of the nitric oxide for that element; and the circumstance of this process being repeated over and over again by the same portion of nitrous gas, accounts for the small quantity of nitre required in this curious process.

When the water in the chambers is rendered sufficiently acid, which is judged of by its specific gravity, it is drawn off into leaden boilers, where it is evaporated down to a certain density; after which, as it would then act upon the lead, it is transferred to platinum boilers supplied with still-heads, and there is brought to its proper degree of concentration by further distilling off a portion of the residuary water. This last process was formerly conducted, at great risk and inconvenience, in glass retorts: its present improvement shows a most important application of platinum, which is not acted upon by the boiling acid. Of late, sulphuric acid has been largely manufactured from the sulphur obtained by roasting common pyrites (sulphuret of iron); one of the objections to which is, that it almost always contains more or less arsenic, by which the resulting acid is therefore contaminated. The acid made from Sicilian sulphur is indeed not always free from this mischievous impurity.

Sulphuric acid is a limpid colourless fluid, of a specific gravity of 1·8. It boils at 620°; it freezes at 15°. But the temperature at which the diluted acid congeals is singularly modified by the quantity of water which it contains. When of the specific gravity of 1·78 (which may be regarded as a compound of 1 atom of dry acid and 2 of water), it freezes at 40°, and remains solid for a long time at several degrees above that point: if the density be either diminished or increased, a greater cold is required to congeal it.

It is acrid and caustic, and intensely acid in all its characters, even when largely diluted. Its attractions for bases is such that it separates or expels all other acids more or less perfectly from their combinations. Its affinity for water is such that it rapidly absorbs it from the atmosphere, and when mixed with water much heat is evolved: thus by suddenly mixing 4 parts of the acid and 1 of water at 60°, the temperature rises to 300°. Its attraction for water also causes the sudden liquefaction of snow; and if mixed with it in due proportion, an intense cold is the consequence. It acts energetically upon animal and vegetable substances, generally charring them, and often, as in the case of *sugar*, with singular rapidity.

This acid, as it usually occurs in commerce, under the name of *concentrated sulphuric acid*, is a compound of 1 atom of anhydrous acid and 1 of water. The anhydrous sulphuric acid is constituted of 16 sulphur (1 atom), and 24 oxygen (3 atoms); its equivalent, therefore, is $16 + 24 = 40$: this is the composition of the acid as it exists in the *anhydrous sulphates*. The strongest liquid acid consists of 40 of the dry or anhydrous acid (1 atom), and 9 water (1 atom), and is therefore represented by the equivalent $40 + 9 = 49$.

Sulphuric acid is an article of great commercial consumption; its purity and value are judged of by its specific gravity. Upon this subject Dr. Ure's tables may be consulted, which show the quantity of real or *dry*, and of commercial acid, in diluted acid of all densities.

By the term real, dry, or anhydrous sulphuric acid, we mean that which exists in the sulphates, and which may be obtained in a separate state by distilling protosulphate of iron, or green vitriol, at a high temperature: there comes over a dense brownish liquid, which emits vapour when exposed to air, and has hence been termed *fuming sulphuric acid*. On putting this into a retort to which a receiver surrounded by ice or snow is carefully adapted, and heating it gently, a vapour passes over, which condenses into a white crystalline solid; this, which is *anhydrous* or *glacial* sulphuric acid, liquefies at about 70°, and evaporates at about 112°. Yet, when combined with such portion of water as constitutes the above described liquid acid, it is one of the most fixed of fluids. It hisses when dropped into water in consequence of the great heat evolved.

The ready test of sulphuric acid is a soluble salt of baryta; the solution of chloride of barium is generally used, which, when dropped into any solution of free or combined sulphuric acid, announces its presence by a white cloud, or precipitate of *sulphate of baryta*, which is insoluble in nitric acid: this precipitate, when collected, and well washed and dried, consists of 77 baryta and 40 sulphuric acid; so that 117 is its equivalent, and this weight indicates 40 of the dry acid. In the same way sulphuric acid, and the sulphates, are tests of baryta.

SULPHURIC ETHER. *See* ETHER.

SULPHUROUS ACID. This acid consists of 16 sulphur + 16 oxygen; its equivalent being 32. It is obtained by heating sulphuric acid in contact with certain metals, which abstract an atom of its oxygen; such, for instance, as silver or mercury. It is also formed by burning sulphur in oxygen gas. One volume of water takes up about 30 volumes of sulphurous acid gas; so that it requires to be collected and preserved over mercury, or in dry stoppered phials. It has the well-known suffocating odour of burning sulphur, and is possessed of considerable bleaching powers; so that the fumes of burning sulphur are often used to whiten straw, and certain silk and cotton goods; and when certain flowers, such as violets, dahlias, &c., are exposed to such fumes, or to sulphurous acid, their colours are mostly destroyed. Upon other colouring matters it has little effect. 100 cubic inches of sulphurous acid gas weigh between 67 and 68 grains; its specific gravity compared with atmospheric air being 2·22. It extinguishes flame, and kills animals. When subjected to the pressure of about two atmospheres, or when cooled down to 6°, it assumes a liquid form; and in this state it evaporates with such rapidity at common temperature as to produce a most intense degree of cold, so that by its aid chlorine may be liquefied and mercury frozen. It combines with bases, and produces a class of salts called *sulphites*; they are characterized by emitting sulphurous acid when acted upon by sulphuric acid, and by becoming converted into sulphates by oxidizing agents.

SU′LPHUR SALTS. Chemists have lately applied this term to the *double sulphurets*. The sulphurets of the most electro-positive metals have been termed *sulphur bases*, such as the protosulphuret of potassium, sodium, barium, &c.; whilst the sulphurets of arsenic, antimony, &c., the bisulphuret of carbon, and sulphuretted hydrogen, have been called *sulphur acids*; and the compounds resulting from the union of a sulphuret of the former with one of the latter class are *sulphur salts*.

SU′LTAN. (Sultaun.) In Arabic, *mighty*. Various Mohammedan princes are styled by this title besides the Ottoman emperor or grand sultan, to whom it is commonly given by Europeans, but whose peculiar title of Padishah is more dignified. The princes of the deposed family of the khan of the Crim Tartars are also styled sultan: so also the pacha of Egypt in that country, although not by the court of Constantinople.

SUMACH. (Eng. and Fr.) The powder of the leaves, peduncles, and young branches of the *Rhus coriaria* and *Rhus cotinus*, shrubs which grow in Hungary, the Bannat, and the Illyrian provinces. Both kinds contain tannin, with a little yellow colouring matter, and are a good deal employed for tanning light-coloured leathers; but the first is the best. With mordants, it dyes nearly the same colours as galls. In calico-printing, sumach affords, with a mordant of tin, a yellow colour; with acetate of iron, weak or strong, a gray or black; and with sulphate of zinc, a brownish yellow. A decoction of sumach reddens litmus paper strongly; gives white flocks with the proto-muriate of tin; pale yellow flocks with alum; dark blue flocks with red sulphate of iron, with an abundant precipitate. In the south of France, the twigs and leaves of the *Coriaria myrtifolia* are used for dyeing, under the name of *rédoul* or *rodou*. The imports for home consumption amount to about 200,000 cwt. a year.

SU′MMER. One of the four seasons of the year. The summer season, for the northern hemisphere, begins when the sun reaches the tropic of Cancer, and ends at the following equinox.

SUMMER. (Quasi trabs summaria, *an upper beam.*) In Architecture, any large piece of timber supported on two strong piers or posts, and serving as a lintel to a door, window, &c.

SU′MMONS, WRIT OF. In Law. By the Uniformity of Process Act, 2 W. 4. c. 39. s. 1., it is provided that wherever (in personal actions) it is not intended to hold the defendant to special bail, or to proceed against a member of parliament under 6 G. 4. c. 16., this writ, or process, shall be the commencement of the action. It may issue from either of the four superior courts of common law; and a copy of the writ must be personally served on the defendant against whom it is intended to proceed. The duration of a writ of summons is four calendar months, inclusive, from the day of issuing; but it may be continued by renewals, termed *alias* and *pluries* writ of summons. The amount of the debt claimed (if the action be to recover a debt), with other requisite particulars, must be indorsed on the writ of summons. If the defendant do not appear either personally or by his attorney in answer to the writ, the plaintiff may enter an appearance for him in the proper court, and proceed to declare as if he had appeared.

SU′MPTUARY LAWS. (Lat. sumptus, *expense.*) Laws intended to restrain the expenditure of citizens. Ancient legislation abounded in them. Thus, among the Romans, the Lex Orchia limited the number of guests at a feast; the Lex Fannia restricted the cost of an ordinary entertainment to ten *asses*, and so forth. There were anciently many laws in England to restrain excess

in apparel; but they were all repealed by 1 J. 1. c. 25. It is said, however, that one ancient statute, 10 E. 3. st. 3., which orders that no man shall be served at dinner or supper with more than two courses, remains unrepealed. It is truly said by Montesquieu, that sumptuary laws are of all laws the most inefficacious and most constantly violated.

SUN. (Ger. sonne.) In Astronomy, the central body of our system, about which all the planets and comets revolve, and by which their motions are regulated and controlled. In Physics, the sun is the source of light and heat; and therefore the primary cause of all the motions and changes effected on the surface of the earth by those great agents of nature.

Apparent Magnitude of the Sun. — The sun presents to the naked eye the appearance of a luminous circular disc, subtending an angle of rather more than half a degree. But on measuring accurately the diameter of the disc by means of a micrometer, it is found to be not always the same, but subject to an annual variation. In fact, as the earth describes an ellipse, of which the sun occupies one of the foci, its distance from the sun is constantly changing, and the variation of the sun's apparent diameter is a necessary consequence of the change of distance. When the earth is in its perihelion, or point of its orbit nearest to the sun, the sun's apparent diameter is 32′ 35·6″; and when the earth is at its aphelion, or most distant point, the apparent diameter is 31′ 31·0″. The mean apparent diameter, or diameter at the sun's mean distance, is 32′ 2·9″.

Distance of the Sun. — The sun's true distance is found from his horizontal parallax. This is so small a quantity that it would scarcely be possible to determine it in the usual way by observations made on opposite sides of the earth; but the astronomical phenomena of the transits of the planet Venus over the sun's disc afford the means of determining it with the utmost precision. From such phenomena the parallax has been found to be only 8·6″; that is to say, if an observer could be placed at the centre of the sun, the earth's semidiameter would be seen by him under an angle of 8·6″. From this it follows that the mean distance of the sun from the earth must be at least equal to 24,047 times the earth's radius; and as the radius of the earth is nearly 4000 miles, it follows that the sun's true distance from the earth must be about 96,000,000 miles. *See* PLANET.

In order to obtain a more distinct idea of this enormous distance, we may compute the time in which it would be passed by some of the swiftest motions with which we are acquainted. A 24 lb. cannon ball, fired with a charge of 8 lbs. of gunpowder, is projected with a velocity of about 1600 feet in a second. Supposing it were to continue to move towards the sun with the same uniform velocity, it would require ten years to reach his surface. A body travelling with the velocity of sound would require about five years to pass from the sun to the earth. Light itself, which travels with the astonishing velocity of 192,500 miles in a second, only reaches the earth eight minutes and eighteen seconds after leaving the sun's surface.

Knowing the distance and apparent diameter of the sun, it is easy to compute its real dimensions. A body which subtends an arc of 32′ 3″ of a circle, whose radius is 96,000,000 miles, must have a real diameter of 892,000 miles; which, therefore, is the diameter of the sun. Or, since the true diameter of the sun must have to the diameter of the earth the same ratio which the sun's apparent diameter as seen from the earth has to the earth's apparent diameter as seen from the sun, that is, a ratio of 32′ 3″ to 8·6″, or of 111·8 to 1, it follows that the sun's diameter must be nearly 112 times the diameter of the earth. Hence the volume of the sun must be 1,397,415 (the cube of 111·8) times, or, in round numbers, 1,400,000 times the volume of the earth. The mean distance of the moon being rather less than 60 times the earth's radius, if the sun's centre were placed at the centre of the earth its surface would be at twice the distance of the moon's orbit; and the volume of a sphere whose radius is equal to that of the moon's orbit would only be an eighth part of the volume of the sun. The sun's volume is 500 times greater than the volumes of all the planets taken together.

Mass and Density of the Sun. — The magnitude and distance of the sun are determined by direct observation; his mass as compared with that of the earth is deduced from the law of universal gravitation, and the theory of central forces. The earth revolves round the sun at a given distance, and in a given time; and from these data the centrifugal force becomes known. But the force which counteracts this centrifugal force, and compels the earth to move in its elliptic orbit, and prevents it from flying off in a tangent to that orbit, is the sun's attraction. Hence the solar attraction is equal to the centrifugal force. But the earth's attraction at its surface is a known force, being that which causes a heavy body to fall through $16\frac{1}{10}$ feet in a second of time; and consequently, from the known law of diminution proportionally to the inverse square of the distance, the earth's attractive force at any distance from the surface also becomes known. Now, on comparing the centrifugal force due to the earth's motion in its orbit with the force of terrestrial gravity on a body at the distance of the sun, it is found that the former exceeds the latter in the ratio of 354936 to 1. But when the distance is the same, the attractive forces of two bodies are directly as their masses or quantities of ponderable matter; and hence the sun's mass is 354936 times greater than that of the earth. It is also found to be about 800 times greater than the aggregate of the masses of all the planets and satellites.

The density of a body is directly as its mass, and inversely as its volume. If, therefore, we call the density of the earth 1, the ratio of the density of the sun to that of the earth will be as 354936 ÷ 1397415 to 1, or as ·0254 to 1; whence the sun's density is about one fourth of that of the earth.

In order to compare the force of solar gravity at the sun's surface with that of terrestrial gravity at the earth's surface, we must recollect that the attraction of a body on an exterior point is directly as the mass of the attracting body, and inversely as the square of the distance of the point from its centre. Hence, since the sun's mass is 354936 times that of the earth, and the radius (or distance of the surface from the centre) 111·8 times that of the earth, if A denote the force of solar gravity at the sun's surface, and B that of terrestrial gravity at the earth's surface, then

$$A:B::\frac{354936}{(111\cdot 8)^2}:\frac{1}{(1)^2};$$

or A is to B as 27·9 (nearly) to 1. A body, therefore, which at the earth's surface weighs one pound, would weigh 27·9 pounds if carried to the surface of the sun. "An ordinary man would not only be unable to sustain his own weight on the sun, but would be literally crushed to atoms under the load." (*Herschel's Astronomy.*)

Rotation of the Sun. — The sun's surface, when viewed through the telescope, is frequently diversified with a number of dark patches or *spots*, which being observed from day to day are found not to remain in the same place, but to move across the surface, without, however, changing their relative positions. These phenomena are accounted for by supposing the sun to have a rotatory motion about an axis from west to east. From a comparison of the best observations Delambre found the period of rotation to be about 25 days; and that the sun's equator is inclined to the ecliptic in an angle of about 7° 20′, and intersects it in a line which makes an angle of 80° 21′ with the line of the equinoxes. The observations of the spots are, however, subject to great uncertainty; but the *fact* of rotation from west to east, or in the same direction as the earth and all the other planets, is established.

Spots of the Sun. — The solar spots, to which allusion has just been made as furnishing the elements of the sun's rotation, present very remarkable appearances, and have been the subject of numerous theories respecting the nature and physical constitution of the sun. They began to attract attention soon after the discovery of the telescope, and their phenomena are described with sufficient accuracy by Hevelius and Scheiner. In form they are exceedingly irregular; and, when watched attentively for some time, are observed to enlarge and contract, and to change perpetually their form and outline. Frequently they disappear without approaching the edge of the disc, and break out suddenly in places where none were seen before. Sometimes a spot has been seen to break up into several parts, and the fragments to separate from each other, as if acted upon by an explosive force. The *nucleus* of a spot is perfectly black, and sharply defined; and is surrounded by an *umbra*, or border of a fainter shade. In the neighbourhood of large spots, or in places where they are numerous, bright streaks, or portions more luminous than the general surface of the sun, called *faculæ*, are frequently seen. Among these faculæ spots are often observed to break out; and when this does not happen they are generally succeeded by spots, larger in proportion to the brightness of the antecedent faculæ. The region of the spots is generally confined to the equatorial parts of the sun, within about 30° of the equator; but occasionally they are observed over the whole disc.
